Above the ionization voltage, e_1 and c_2 remain nearly constant. c_1 and e_2 both increase very rapidly (Fig. 13.) From our experimental data with both the cable models and with flat air spaces (Appendix IV) we know that immediately above the ionization voltage e_2 increases more rapidly than c_1. Hence, the expression under the radical sign increases rapidly, which causes a rapid increase in sine ψ or in the power factor of the combination. Also, when ionization commences, the left-hand term becomes small in comparison with the right-hand term. At higher values of the voltage E, c_1 commences to increase very rapidly also, and the rate of increase of the right-hand expression becomes less than the rate of increase in E. As a result, with further increase in E. sin ψ and hence the power factor of the combination commences to decrease. Therefore, above the ionization voltage, sin ψ at first increases rapidly, reaches a maximum and then decreases.

We realize that in a cable the air films are not all ionized simultaneously, but the films nearest the conductor probably ionize first, due to the higher gradient there, and a greater and greater number further from the conductor become ionized as the voltage is increased. Hence, the power factor is determined by the summation of the effects of the separate films. This results in power-factor curves which rise less rapidly and which have more gradual changes in slope, as is shown by comparing the curves taken with actual cables with those of model cables.

Determining as closely as possible the constants of our glass cable models, we have calculated the power factor for the model whose curves are shown in Fig. 5 using the foregoing equation. We assumed that the ionization voltage began at a definite value of 7.5 kv. In Fig. 15 the experimental curve and the calculated curve are plotted. In our opinion, the agreement between the curves is unusually good, particularly for dielectric phenomena of this character. These curves show that the foregoing theories are correct not only in a qualitative sense, but substantially so in a quantitative sense as well. They also show that the decreasing power factor is not caused by such phenomena as saturation of ionization but is merely the natural result of a combination of series capacitances, of this character. We conclude from this that when ionization exists in cables the power factor alone cannot be used to determine the degree of ionization in any one cable or to compare the ionization characteristics of different cables.

It is apparent that it is possible to calculate with a fair degree of precision the effects which may be expected in solid and gaseous dielectrics, provided we know the constants of the solid medium and the con stants of the gaseous films.

It has been recognized for some time past that, although the paper itself has lower dielectric strength than the impregnating compound, the dielectric strength of the cable is increased by using paper in combination with the compound. This is probably

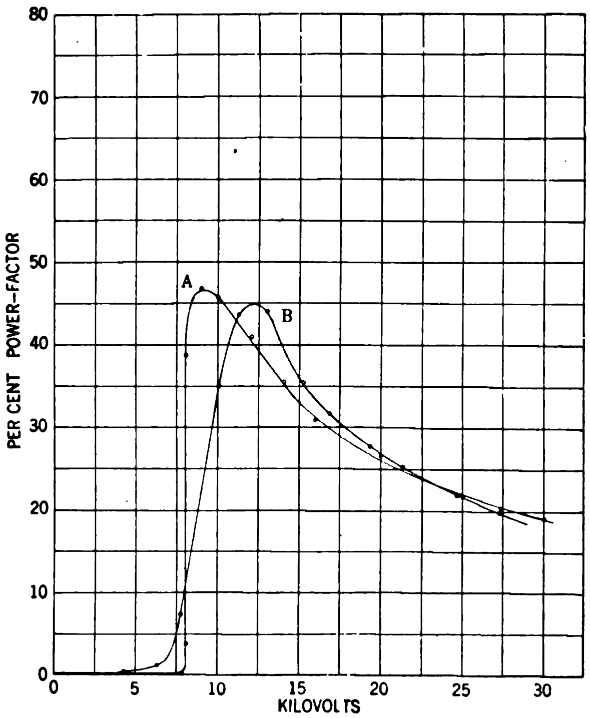

FIG. 15—CABLE MODEL. GLASS-AIR DIELECTRIC

A. Calculated
B. Experimental

due to a considerable extent to the fact that the paper acts as a barrier,[15] which prevents or restricts the motion of the ions through the insulation. We felt it worth while to study these effects with our cable models. The glass tube of the model whose characteristics are shown in Fig. 11 was wrapped tightly with dry manila paper, such as is used for insulating cables. The brass tube was then slid over the paper. Thus we produced a cable model having a composite insulation of glass, air and paper.

Fig. 16 shows the curves of power factor, watts loss and capacitance plotted with kilovolts which we obtained with this model cable. The ionization point

15. William A. Del Mar, Electric Cables, p. 84.

started at a lower voltage than with air and glass alone as the dielectric. This would be expected. The power factor increased to a first maximum of 24 per cent at 7 kv. When the voltage was increased above 7 kv. the power factor decreased to a minimum of 18 per cent at 16 kv., after which it increased again to a second maximum of 27.5 per cent at 22 kv. Beyond this the power factor continued to decrease, reaching at 32.5 kv. nearly a constant value. The capacitance curve increases steadily with increased kilovolts, but shows changes in slopes corresponding to the maxima and minima of the power-factor curve. The watts loss curve begins to increase with the first increase of power factor and then increases suddenly when the power-factor curve begins to increase for the second time at 16 kv.

Fig. 16 indicates that this composite cable has a second ionization voltage. The paper was removed and examined, and found to be pierced throughout by numerous fine pinholes. This effect could not be found unless the voltage were carried up beyond the second ionization voltage. The explanation of the second ionization voltage is now obvious.

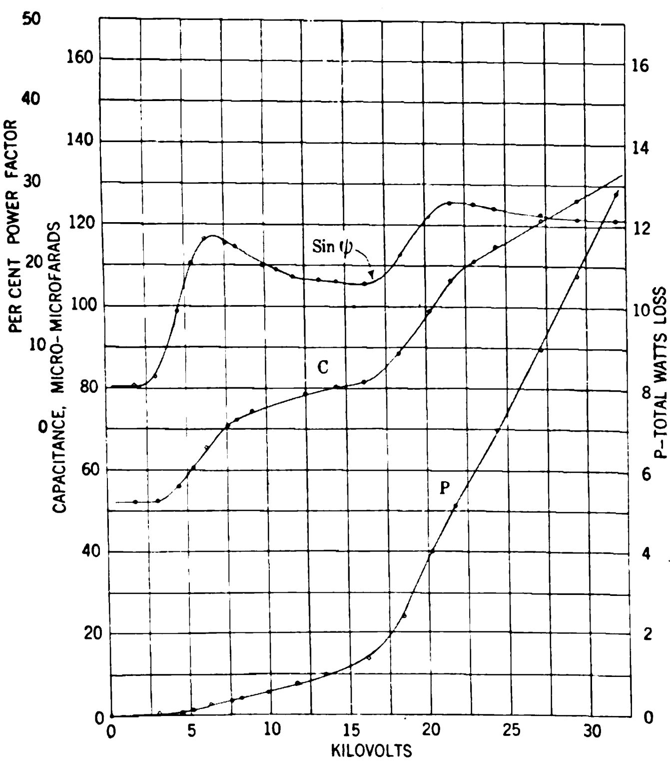

Fig. 16—Cable Model. Glass-Air-Paper Dielectric
20 deg. cent. 60 cycles per second

As the impressed voltage is increased, the voltage across the air spaces reaches its maximum value and does not increase further. Hence the gradient in the paper and the gradient in the glass increase more rapidly with further increase in impressed voltage. When the gradient in the paper becomes sufficiently high, the ions striking its surface are drawn through causing perforations. A number of ions concentrating at one point causes a pinhole. The restricted ionization current density prevents dynamic rupture. Because of the perforations, the dielectric and the barrier actions of the paper are in part destroyed. Any increase in impressed voltage now occurs almost entirely across the glass tube and the power factor begins to increase and then decrease again in the manner which was discussed in connection with Figs. 5 and 11.

This suggests that one of the requisite qualities of paper which is to be used for cable insulation may be its barrier action under conditions similar to the foregoing.

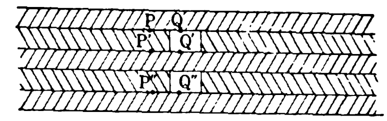

Fig. 17

The foregoing experiments and the resulting analyses suggest hypotheses which may explain the origin of "tree designs" and the incipient causes of breakdown. Fig. 17 shows a magnified and perhaps exaggerated section of paper insulation in which two spaces, one on each side of a paper tape, happen to occur directly opposite each other, due to the tapes not touching. Owing to the fact that the tapes do not quite touch and the compound does not quite fill all the voids so formed, gas films exist in spaces Q' Q and Q' Q''. At low voltages, below the ionization voltage, the potential gradient across the air films and the corresponding layer of paper will be equal in most cases. Hence no potential difference will exist between points P and Q, P' and Q', P'' and Q''. Above the ionization voltage the gradient through the paper increases. The gradient through the air-spaces cannot increase beyond a limiting value as already demonstrated. This causes a potential difference to exist between points P and Q, P' and Q', P'' and Q''. Therefore, there will be voltage gradients tangential to the surfaces of the paper which may cause creepage or tangential currents which carbonize the surfaces and ultimately result in "tree designs." This creepage may be followed by discharges over the edges of the tape, and these discharges are likely to be more or less oscillating in character and of high frequency. These discharges cause further local heating and further destruction of insulation. The barrier action of the paper at Q' may also be destroyed, as with the authors' paper-glass models, causing increase in the watts loss (Fig. 16), and ultimately producing hot spots. Hence, these effects are all cumulative, and eventually rupture will occur at this point.

Conclusions

1. When corona occurs in air spaces, the increase in energy loss begins at a lower voltage gradient than the increase in capacitance.

2. With ionization in a gas, the voltage gradient must always be greater than zero.

3. The gradient in an ionized gaseous dielectric is finite but cannot exceed a definite maximum value. This maximum value is the breakdown gradient for each particular condition.

4. The ionization current is limited or restricted by the solid dielectric.

5. When the voltage gradient in cables has reached a value sufficiently high to ionize all the gas films in the dielectric, the ionization loss becomes proportional to the cable charging current.

6. The power factor is a direct function of the relative capacitance of the solid dielectric and air spaces in series. Hence, power factor of itself does not show the degree of ionization which exists in a cable.

7. The power factor due to a combined solid and ionized gaseous dielectric can be calculated if the constants of the two dielectrics are known.

8. Restricted ionization effect has been called "the barrier action of paper" in high-voltage cables and a method is suggested whereby it can be measured and the relative quality of cable papers be determined.

9. "Tree designs" are probably due to tangential gradients set up in the cable as a direct result of ionization.

10. Ionization causes progressive deterioration due to the high-frequency oscillations accompanying these internal discharges. The increased local temperatures or hot spots, due to ionization, tend to exaggerate these effects.

The authors are indebted to the members of the electrical engineering staff of the Harvard Engineering School for their cooperation in this research and particularly to Professor H. E. Clifford for his suggestions in the preparation of the paper.

Abridgment of Paper on Concluding Study of Ventilation of Turbo Alternators Multiple Path Radial System

BY C. J. FECHHEIMER[1] and G. W. PENNEY[1]

Synopsis.—*In 1924 two papers were presented before the A. I. E. E. on Turbo Alternator Ventilation. In one of the papers tests on two models for two methods of ventilation were described, and data from the tests were given. The other paper contained a mathematical treatment for one system of ventilation, which was based upon the data obtained from the tests. It was recognized that the tests were not sufficiently accurate to evaluate the loss coefficients, nor was it possible to obtain data on the distribution of volumes for the intake vents. For that system, (see Fig. 1), it was found that the influence of rotation upon total volumes and their distribution could be neglected; consequently the investigation could be continued on stationary models. Those tests, the methods of determining the losses and the equations derived therefrom are given in this paper.*

Since the effect of rotation could be neglected, the test could be reduced to a model which represented only one axial row of vent ducts. On this model the stator vent ducts were imitated by square brass tubes with a plaster of paris restriction cast in one end to imitate the vent duct restriction so that the pressure drop obtained for either direction of flow was approximately the same as in a stator vent. A long steel channel or duct represented the section of the air-gap. Some of these brass tubes, representing intake vents, lead from a large sheet metal box to the gap channel. Other tubes, representing discharge vents, lead from the gap channel to the atmosphere. The gap channels could be inter-changed readily to represent various sizes of air-gaps. Any desired number of intake and discharge tubes could be used so as to represent any desired layout of the machine.

The volumes in individual intake tubes were measured by reading on a manometer the drop in pressure from the intake chamber to a point a little ways down the tube. For the discharge tubes small impact tubes were employed. Each tube was carefully calibrated before making any other tests; a thermal volume meter was used for calibrating an orifice, and the orifice was used for the tube calibrations. Various difficulties arose, and the means of overcoming them are given.

Tests were made with a group of intake vents, and the losses were separated into (1) those in the tubes; (2) those accompanying a right angle turn; (3) those due to a stream of one velocity impinging upon a stream of another velocity; (4) those due to sudden increase in velocity; (5) those due to surface frictions. Similar tests on the discharge side showed that the losses there could be separated into (1) those in the tubes; (2) those accompanying a right angle turn; (3) those due to sudden decrease in velocity; (4) those due to surface friction.

The losses were put, for the most part, into comparatively simple expressions. They were then combined in order to obtain final solutions. There was no difficulty on the intake side in obtaining a differential equation which admitted of ready integration. On the discharge side, however, it was necessary to use approximations. With the aid of the final equations the total volumes and their distribution can be calculated for a given pressure drop. One difficulty is that the equations include trigonometric and hyperbolic functions of quantities involving the distance between the point where the gap velocity is maximum to the points where the gap velocity is zero. The latter point, called the "balance point" is not known, and a simultaneous solution of the transcendental equations needed for its determination, is impossible. Suggestions for a direct simple approximate solution are given, which may be followed by trial and error methods. In most of the applications, only one or two trials were required.

The equations were checked for accuracy by comparison with tests made on the tubes, on the turbo model of 1922 and 1923, and with those on an actual machine. The agreement in total volumes was very close, and is considered to be quite good for distribution also.

1. Both of the Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Abridgment of paper presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies upon request.

Introduction and Purpose

At the 1924 Midwinter Convention of the American Institute of Electrical Engineers, two companion papers were presented on the general subject of Ventilation of Turbo Alternators[2]. One dealt with a description of two models on which the experiments were made, the methods of conducting tests, together with representative data and the important conclusions. The other paper (by D. Bratt) was mathematical, the equations being derived from an ideal system, in which all losses in the air-gap were neglected; he increased the losses empirically on the discharge side, so that the measured and calculated total pressure drops agreed. Bratt's equations applied to the system of ventilation in which the air flows axially in the air-gap, shown schematically in Fig. 1. That system was the one adopted by the Westinghouse Company, as tests on the turbo models indicated its superiority over the other system in which the air flows circumferentially in the air-gap.

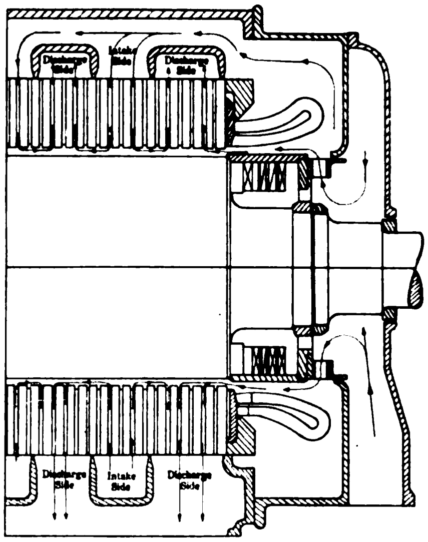

Fig. 1—Scheme of Ventilation of Turbo Alternator

The experimental data obtained from the large wooden models were too inaccurate to enable an evaluation to be made of the losses of head at the turns and other parts of the air circuit so as to incorporate them in the equations. Furthermore, no method was then, or is now, available for measuring the volumes in the individual intake vent ducts. It was recognized then that it was an erroneous assumption to consider that all of the additional losses were on the discharge side, as some were on the intake side as well. In order to enable the designer to calculate the volumes of air and their distribution, further experiments were made as described in this paper.

2. "An Experimental Study of Ventilation of Turbo Alternators" by C. J. Fechheimer, and "Multiple-Radial System of Cooling Large Turbo Generators" by Donald Bratt, A. I. E. E., 1924, pp. 476 and 467.

Perhaps the most important conclusion reached as a result of the earlier experiments was that with a ventilation system as shown in Fig. 1, the influence of rotation upon the total volume of air is nearly negligible. Thus, the total volumes with the rotor vents closed, and with pressures of the order of five inches of water, were reduced about four per cent by changing the rotor speed from 0 to 3600 rev. per min. (surface velocity of 24,600 ft. per min.) With the rotor vents open, and with higher pressures, there was even a smaller reduction in volume; consequently the change between standstill and normal speed could be ignored in machines as are ordinarily built, with pressures of 10 in. of water or more.

A second important conclusion was that on the discharge side the axial distribution of volume in the vent ducts was made somewhat more uniform by the influence of rotation. The influence is less the larger the air-gap and for the air-gaps usually employed the effect of rotation upon axial distribution is quite small.[3] Undoubtedly on the intake side, there is likewise a modification in axial volume distribution due to rotation, but now, from theoretical considerations, there are probably greater differences between maximum and minimum vent-duct velocities than at standstill. But the change is doubtless quite small with the usual size of air-gap. In the large machines the coils are sunk so that there is an axial passage above them in which the flow is not disturbed appreciably by rotation. (This may be seen from the outlet vents by a comparison of Figs. 33 and 34 in the 1924 paper). Also, the tests on the turbo model were made at the reduced total end-bell pressure of about 3.3 in. of water. In the large modern machines, the end-bell pressure is considerably higher, 10 in. and more. Then all the velocities in the vents and gap are greater, and the influence of rotation upon vent duct volume distribution becomes still less. Certainly, whatever the influence of rotation is, it is sufficiently small to justify the assumption that it may be neglected.

This then meant that the study could be continued on stationary models. They could be of such reduced size that the tests could be made in a laboratory instead of in a factory, and thus not conflict with production. The conditions that obtain in a machine with axial flow in the gap are the same for all positions, circumferentially, so that a study of flow with one set of vents would be sufficient. The construction of the laboratory apparatus and the manner of conducting the experiments have been fully justified by the close agreement between the wooden turbo model and machine data and the laboratory data.

Apparatus

The vent ducts were imitated by square, brass tubes, two of which are shown in Fig. 2. From a knowledge

3. See Figs. 34 and 35 on pp. 495 and 496 of 1924 A. I. E. E. Transactions.

of the pressure drops in vent ducts obtained from earlier laboratory tests on small ducts, it was possible, by calculation, to determine how to shape the sections within the square tubes, so that the pressure drop in the individual tube would approximate the drop in a vent duct for either direction of flow. A special mandrel was made and plaster of paris was cast about this mandrel on the inside of the tubes.[4] It was found that because of lack of uniformity at the ends of the plaster of

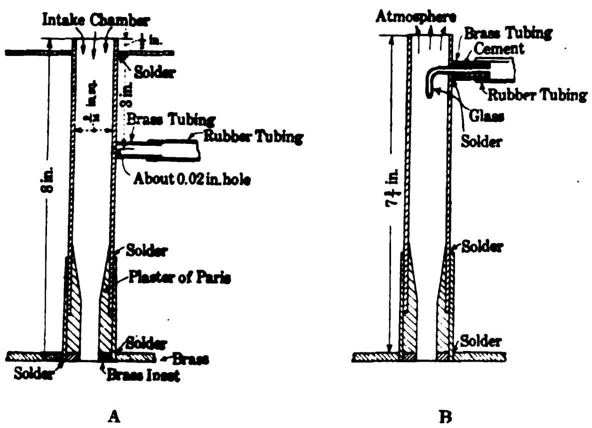

FIG. 2—CONSTRUCTION OF SQUARE TUBES USED IN THE EXPERIMENTS
(a) Tube representing intake vent duct
(b) Tube representing discharge vent duct

paris, there were many irregularities in the test results. Consequently, small brass insets were made as shown in Fig. 2, and the plaster of paris behind them was formed accurately to dimensions.

Fig. 2A shows one of the intake tubes and Fig. 2B one of the outlet tubes. The air enters the intake tubes from a relatively large chamber and there is a loss of head at and just beyond the entrance of air to the tube

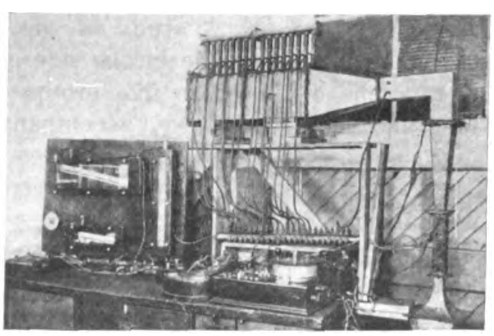

FIG. 3—FIRST SET-UP, IMITATING THE INTAKE SIDE OF A TURBO ALTERNATOR

In addition, there is the velocity head itself ($v^2/2\,g$) so that the total difference in pressure from the large intake chamber to a point a little distance down the tube is approximately 1.5 $v^2/2\,g$. Hence, if a manometer is connected between the large intake chamber and a point down the tube, the readings should be of of approximately one-half of a velocity head ($1/2\,v^2/2\,g$).

4. Metals of various kinds had been tried, but had been abandoned.

such order that they could be observed with considerable accuracy. That was the principle used for measuring the volumes in the intake tubes the construction being indicated in Fig. 2A. A sample tube was tried out before all the tubes were made and the method was found to be satisfactory.

On the outlet side, the air discharges from the individual tube directly into the atmosphere. Neglecting what small friction drop there is in the tube, the static pressure a short distance from the end is nearly the same as that of the surrounding atmosphere. Consequently, the method used for measuring volumes on the intake side could not be applied to the discharge side. The construction that was adopted is shown in Fig. 2B. Inside the large square brass tube was a small impact tube which was connected by the usual rubber tubing to a manometer, the other side of the manometer being open to the atmosphere.

In using the intake tubes, the manometer was connected by means of rubber tubing between the round brass tube soldered to the square tube and the relatively large intake chamber in which latter the velocities were so low that the influence of velocity head could

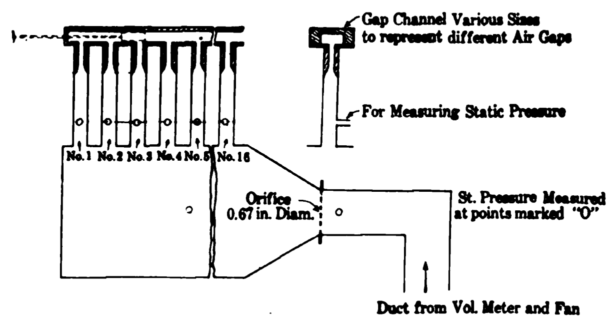

FIG. 4—SCHEME OF FIRST SET-UP, IMITATING THE INTAKE SIDE OF A TURBO ALTERNATOR

be neglected. On the discharge side, the manometer was connected to the impact tube. Each tube was carefully calibrated before any other tests were made. Due to small errors in construction which necessitated referring to the calibration data when the final data were used, the calibrations differed slightly from one another.

All tubes were soldered into brass plates about 0.25 in. thick, and were assembled in several combinations. Channels of various sections to imitate different air-gaps were made to bolt to the brass plates, rubber gaskets being used to eliminate leakage. Groups of tubes could be joined together at their ends, for which suitable flanges and bolts were provided.

There were three set-ups, two of which are shown clearly in the illustrations, Figs. 3 and 6. In Fig. 3, which shows the first set-up, intake conditions only are imitated. In Fig. 4 it is shown schematically. The second set-up imitated the discharge only and it is shown schematically in Fig. 5. In Fig. 6, for the third set-up, the ventilating system of one-half of

a generator, with one intake chamber at either side of the center line is simulated.

The apparatus was constructed so that any desired combination of intake and discharge vents could be obtained, thereby imitating the ventilating system of a machine, either in part or whole. The blower used does not appear in the photographs. It was capable of delivering the volumes required at pressures up to 10 in. of water.

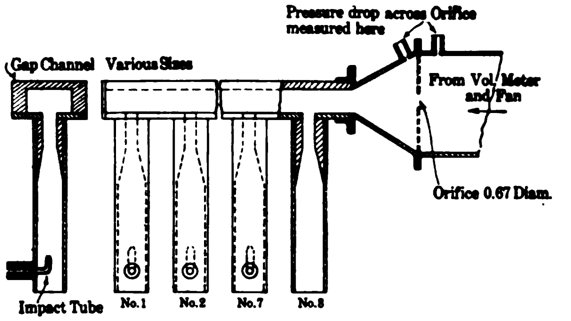

FIG. 5—SCHEME OF SECOND SET-UP, IMITATING THE DISCHARGE SIDE OF A TURBO ALTERNATOR

DIFFICULTIES IN MEASUREMENT

1. Measurement of volumes. It was at first thought that the impact tube method of measuring volumes as used for the discharge tubes would be more reliable than the entrance pressure drop method used for the intake tubes, since impact measurements are usually from which the glass impact tube had been removed. The ratio of readings taken with them did not remain position just beyond one of the square discharge tubes

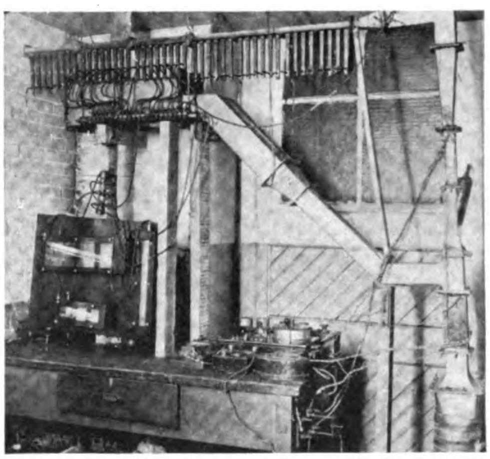

FIG. 6—THIRD SET-UP, IMITATING THE VENTILATING SYSTEM OF HALF OF A TURBO ALTERNATOR

more dependable than are those for static pressure. It was found, however, that the reverse was the case in these experiments. Thus, when taking observations of discharge volume distribution with several tubes open, some of the points did not lie on a smooth curve, which was not the case for the intake tubes. The discrepancy was of the order of three or four per cent. Four small impact tubes were supported in fixed, showing that the character of flow changed, and the other impact tubes undoubtedly were similarly affected. Apparently, the highly turbulent state in the gap channel, and immediately after entrance to the square tube was not entirely eliminated before the impact tube was reached. It is well known that, with some turbulent states, the flow may change and be periodic. These tests also proved that the character of flow in the tube is affected by the magnitude of the gap velocity. This was indicated by the fact that the volume in a duct depended somewhat upon the gap velocity, as well as upon the square root of the static pressure difference. Subsequent reference to this will be made. For the intake tubes the velocity in the large chamber was negligible, so that any flow there did not influence the drop to a point where the readings were taken.

2. Pressures in the air-gap. In order to determine where the losses of head occurred, it was necessary to know the static pressure in the air-gap as well as the average velocity there. The tests made by the "toy balloon" method described on page 496 and shown in Fig. 37 in the 1924 A. I. E. E. TRANSACTIONS, indicated that a reasonably accurate measure of the gap static pressure could be obtained by closing a vent and then observing the pressure in the vent some distance from the gap. That method was tried in these tests also. To determine the air-gap pressure at a given tube, the two adjacent tubes were closed at their far ends. The manometer readings were then the static pressure in the gap. The average of these readings for the two adjacent tubes was taken to be the desired static pressure. That this method was satisfactory was proven by subsequent tests. It was used chiefly for the discharge tubes, but it was found to check on the intake side also.

DETERMINATION OF LOSSES

A. On the Intake Side. A study of the possible sources of losses of head on the intake side indicated that they could be divided into five groups: 1, loss within the radial vent duct; 2, loss accompanying the turning of a right angle; 3, loss due to sudden increase in velocity when an incoming stream impinged upon a stream normal to it; 4, loss due to surface friction; and 5, loss at final discharge from the air-gap channel. (This last loss is $\frac{v^2\,o}{2\,g}$, and requires no further discussion). The expressions for the losses are given here; the means for separating them in the experiments are given in the complete paper.

1. Loss within the radial vent duct. The pressure drop in a vent duct had been determined in previous tests and could be represented by the equation

$$\frac{P}{\gamma} = C\,i\,\frac{V^2}{2\,g}$$

(Where p = pressure drop, γ = density, V = velocity

at the minimum section of the duct, and g = acceleration of gravity)[5]. As the velocity head at discharge from the vent duct is $\frac{V^2}{2g}$, the loss within the vent duct is evidently

$$(C_i - 1)\frac{V^2}{2g} \tag{1}$$

2. Loss accompanying the turning of a right angle. The expression just given accounts for the pressure drop through the vent duct, provided the air-gap velocity is negligible. Usually, however, the gap velocity is appreciable which causes an additional difference between static pressure at the entrance of the vent duct and the static pressure in the air-gap. This additional pressure drop is due to the abrupt turn which the stream from the vent duct must make when it strikes the air-gap stream. This pressure drop can be represented by $K_L \frac{v^2}{2g}$ (where K_L is a coefficient, depending on the size of the air-gap and v is the velocity in the air-gap just past the vent duct.)

In addition to this loss in pressure there is a loss in velocity head since the velocity in the gap is almost always lower than the velocity issuing from the vent duct. This loss in velocity can be represented by $\left(\frac{V^2}{2g} - \frac{v^2}{2g}\right)$ and is caused by the sudden decrease in velocity when the air from a vent duct mixes with the air in the gap. The total pressure drop from the intake chamber to a point in the air-gap just past the vent duct is then:

$$\frac{p}{\gamma} = (C_i - 1)\frac{V^2}{2g} + K_L\frac{v^2}{2g} + \left(\frac{V^2}{2g} - \frac{v^2}{2g}\right) + \frac{v^2}{2g} \tag{6}$$

The last term represents the velocity head in the gap.

3 and 4. Loss due to sudden increase in gap velocity and duct friction. As a stream from a vent duct impinges upon the stream in the air-gap, the velocity of the gap stream increases suddenly due to the increase in volume. Considerable loss is produced by the eddies accompanying this sudden increase in velocity, and this loss can be represented by $K \frac{v_2^2 - v_1^2}{2g}$. Where v_2 and v_1 are respectively the gap velocities after and before the sudden increase in gap velocity, and K is a coefficient to be determined experimentally. It was found that K could be so chosen as to include the loss due to the duct friction in the gap as well as the loss due to sudden increase in velocity.

5. A list of symbols is given after the final equations.

Combination of loss expressions on the intake side. Let

P = Pressure in the intake chamber.

p_0 = Pressure in the gap at its discharge point. (This was atmospheric pressure in the tests described above or taken as zero for reference.)

v_0 = Gap velocity at the discharge point.

Then by Bernoulli's equation:

$\frac{P_0}{\gamma} = \frac{p_0}{\gamma} + \frac{v_0^2}{2g}$ + sum of losses from intake chamber to discharge point in gap.

or

$$\frac{P}{\gamma} = \frac{p_0}{\gamma} + \frac{v_0^2}{2g} + (C\,i - 1)\frac{V^2}{2g} + \frac{V^2 - v^2}{2g} + \frac{K_L\,v^2}{2g} + K\frac{v_0^2 - v^2}{2g} \tag{8}$$

The accuracy of this expression for pressure drop was checked by testing a large number of intake combinations. Then, using the measured velocities and the above expression for losses, the pressure drop was calculated for each vent duct and this value was checked against the measured pressure drop. Table I shows a tabulation of these values for one test. The agreement is undoubtedly close and, therefore, the equation was taken to be sufficiently accurate.

TABLE I

I. Vent Tube Number	II. Vel. "V" in Vent	III. Total Calc. Pressure	IV. Total Meas. Press.	V. % Difference
3	9480	8.48	8.18	+3.7

16	1420	8.15	8.18	−0.4

B. On the discharge side. On the discharge side, the air streams flow from the air-gap through parallel vent ducts out to a common discharge chamber. In these tests they discharged into the atmosphere. The losses of head were divided into four groups: 1, loss within the radial vent ducts; 2, loss accompanying the turning of a right angle; 3, loss due to sudden decrease in velocity arising when some of the fluid discharged through a vent duct; 4, loss due to surface friction. For the particular set-up there was also a small loss in the converging duct leading to the gap channel, but this loss does not appear in the machine, in the parts that are fed from the intakes. There is an entrance loss whose magnitude depends upon the entrance conditions in machines at the end-bell ends. Ap-

proximate data obtained in the turbo-model tests in 1923 permit of evaluation of the latter loss with sufficient accuracy.

1 and 2. Loss within the radial vent, and loss accompanying the turning of a right angle. As for the intake vents, the losses in the radial vents were determined at the time the tests on the turbo model

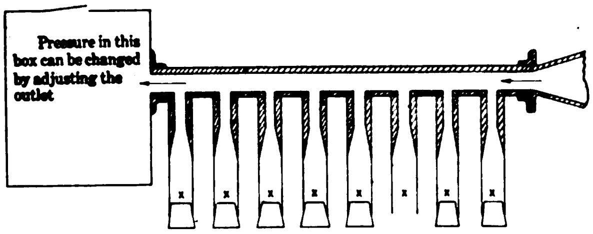

FIG. 7—SCHEMATIC DIAGRAM, SHOWING THE METHOD IN WHICH TESTS WERE MADE FOR EVALUATING LOSS CO-EFFICIENTS ON THE DISCHARGE SIDE

One vent duct was left open. All other vents were closed by rubber stoppers. The pressure in the gap can be changed by adjusting the outlet from the box at the end of the gap so that any combination of velocity and pressure can be obtained. Impact tubes located at points marked "x" give vent duct velocity head if the vent duct is open, or static pressure in the gap if the vent duct is closed by a rubber stopper

were made in 1922 and 1923. They were made with the same apparatus but the direction of flow was reversed. The co-efficient was called C_d, as defined by the equation $\frac{p}{\gamma} = C_d \frac{V^2}{2g}$. The meanings of the symbols are the same as before. It was recognized that the conditions in the machine, or in this model might be different than they were in the small set-up of 1923, because the entrance conditions were different. The loss accompanying the turning of a right angle could not readily be separated from the entrance conditions, and there was little to be gained, if that could have been done without great difficulty. Consequently those two losses were combined, and the new values of the coefficient $C\,d$ takes account of the turning of a right angle, of the entrance loss to the vent duct, and the loss in the vent itself.

In Fig. 8 will be found a plot for one test, No. 3 tube being the only one open. The value of $C\,d$ is not constant, but is dependent upon the gap velocity.

3. Loss due to sudden decrease in velocity. It was shown largely by theory and checked by experiment that when there is a sudden enlargement of cross-section, the loss of head is:

$$\frac{(v_1 - v_2)^{2*}}{2g} \tag{10}$$

v_1 and v_2 are the velocities before and after the enlargement, as given by the volume divided by the cross-sectional area. It may, without much difficulty, be shown that the decrease in velocity in the air-gap to the abstraction of the air through the vent duct, is comparable with the case of sudden enlargement, and probably should be given by the same equation. Equation (**10**) was found to apply with considerable accuracy, except for the case when $v_2 = 0$. Even then the loss considered as part of the total was not great. To check equation (**10**) tests were made in a similar manner to those for the individual tubes, and the gap static pressure on either side of the particular tube was measured.

4. Loss due to surface friction. From the curve in Fig. 8 it will be seen that the friction loss is by no means negligible. It is given by the well-known formula to be found in any standard work on hydraulics:

$$\text{Friction drop} = f \frac{L\ R}{A} \frac{v^2}{2g} \tag{11}$$

Wherein:

f = coefficient of friction
L = Length
R = perimeter of duct
A = Area of cross section of duct
v = velocity
g = acceleration of gravity.

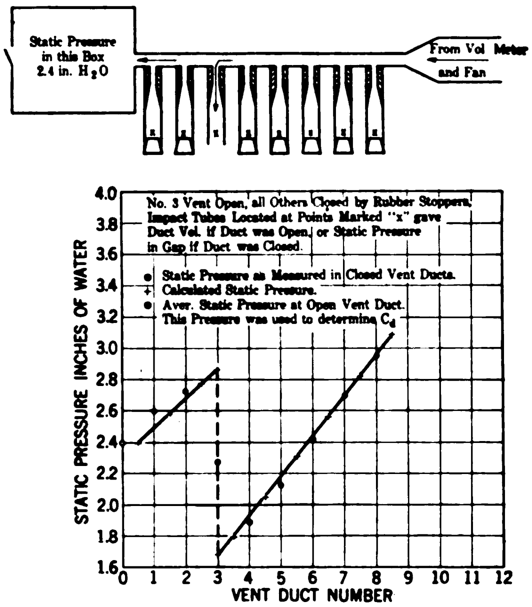

FIG. 8—EXAMPLE OF PLOTTED DATA SHOWING METHOD OF DETERMINING STATIC PRESSURE FOR EVALUATING $C\,d$

If v is in ft. per min., and the density be taken as 0.074 lb. per cu. ft., the friction drop in inches of water is:

$$f \frac{L R}{A} \left(\frac{v}{4030}\right)^2$$

f = about 0.0054

*See Gibson: "Hydraulics and Its Applications." Second edition, pp. 82 and 83. The equation is quite different from what one might at first glance expect:

$$\frac{v_1^2 - v_2^2}{2g}$$

Combination of the equations on the discharge side. Consider the case where the air enters the discharge part of the air-gap from the intake side (that is, not the case where the air enters the air-gap directly from the end-bell—see Fig. 1). Then the static pressure in the gap at that division point between intake and discharge is p_0. The velocity in the gap at that point is v_0. Following the path of a stream of air from that point, to some other point in the gap, the equation by Bernoulli's theorem is:

$$\frac{p_0}{\gamma} + \frac{v_0^2}{2g} = \frac{p}{\gamma} + \frac{v^2}{2g} + \sum \text{losses from the}$$

division point to the point in the gap considered.

$$\frac{p_0}{\gamma} + \frac{v_0^2}{2g} = \frac{v^2}{2g} + C_d \frac{V^2}{2g} + \sum \frac{(v_1 - v_2)^2}{2g} + \sum f \frac{L}{A} \frac{R}{} \frac{v^2}{2g} \qquad (12)$$

Here $\sum \frac{(v_1 - v_2)^2}{2g}$ means the summation of all losses due to sudden decrease in velocity from the division line up to the particular vent duct considered; and $\sum f \frac{L\ R}{A} \frac{v^2}{2g}$ is the summation of friction drops, between the same points, account being taken of the changes in velocity. In equation (**12**) $C\,d\,\frac{V^2}{2g}$ has been written for $\frac{p}{\gamma}$.

When the air enters the gap channel directly, as was the case for the second set-up, or as is the case when the air in a machine enters the gap directly from the end-bell, and the chamber is so large that the velocity head there may be neglected, the static pressure being P, the equation is:

$$\frac{P}{\gamma} = \frac{v^2}{2g} + \frac{p}{\gamma} + \sum \frac{(v_1 - v_2)^2}{2g} + \sum f \frac{L\ R}{A} \frac{v^2}{2g} \qquad (13)$$

This latter equation was used for final checking of the discharge loss coefficients. In Table II the results of one test are summarized.

Final Equations

The expressions which have been obtained give the pressure drop when the velocities are known. However, equations to be useful to the designer must give velocities for a given pressure drop. To obtain these final expressions, the general method used by Bratt in his 1924 A. I. E. E. paper was followed. The assumption is made that there are an infinite number of vent ducts, each of infinitesimal width, instead of a finite number, each of finite width. This assumption is comparable with the one usually made in polyphase alternating-current machinery; that there is a sine wave distribution of magnetomotive forces and fluxes.

For the intake side the expression for losses could be taken just as it has been given and following the method used by Bratt an equation was obtained which had the same form as Bratt's original equation except that now the constants have been determined experimentally[6].

For the discharge side, the equation for losses as it has been given could be reduced to a differential equation but the solution was too complicated to be practical. It was, therefore, decided to make approximations which would alter the form of equation (**13**), and still be close enough for general application. The assumption was made that there were no gap losses, that $C\,d$ was constant and that its value corresponded to the highest gap velocity. This was the highest value for $C\,d$, so that compensated for having ignored the gap losses. At the division, where the gap velocity is maximum, the assumption is the same as for the actual conditions, since the value of $C\,d$ used corresponds to that point, and the gap losses there are zero. At points where the gap velocity is lower, the assumed value of $C\,d$ is too high, but since then the gap losses are neglected, the static pressure, as calculated by Bernoulli's equation, is high. As the vent duct velocity is dependent upon the quotient of the gap pressure and $C\,d$, and as both are high, the error is quite small.

Summary of Final Equations

Intake	*Discharge*
$v = v_0 \dfrac{\sinh \alpha\,(L_i - x)}{\sinh \alpha\,L_i}$	$v = v_0 \dfrac{\sin \beta\,(L\,d - y)}{\sin \beta\,L\,d}$
$V = \dfrac{a}{S}\,v_0 \dfrac{\cosh \alpha\,(L_i - x)}{\sinh \alpha\,L_i}$	$V = \dfrac{v_0 \cos \beta\,(L\,d - y)}{\sqrt{Cd}\,\sin \beta\,L\,d}$

$$P_i = \gamma \frac{v_0^2}{2g}\left[\frac{1 + K - K_L}{\sinh^2 \alpha\ L_i} + (1 + K) + \cot^2 \beta\,Ld\right]$$

$$P_e = \gamma \frac{v_e^2}{2g}\,(1 + k + \cot^2 \beta\,L_e)$$

Note that to compute the velocities on the discharge side adjacent to the end-bell, the above velocity

6. The derivation of the equations is given in the complete paper.

equations may be used, but y and $L\,d$ are now measured from the end-bell end instead of from the division point, V_e must be substituted for v_0, and the value of $C\,d$ must be used that corresponds to v_e instead of to v_0.

In using the equations it is perhaps a little more convenient to take S as the area of one circle of stator vents at the minimum section, and then $L\,d$, $L\,e$ and $L\,i$ are in number of vents instead of in actual lengths.

In the above equations:

$$\alpha = \frac{S}{a}\sqrt{\frac{1 + K - K_L}{C\,i}} \qquad \beta = \frac{S}{a}\sqrt{\frac{1}{C\,d}}$$

a = Cross sectional area of the air-gap.
$C\,d$ = Discharge coefficient in the radial vent ducts.
$C\,i$ = Intake coefficient in the radial vent ducts.
k = Loss coefficient at entrance to gap, end-bell end.
K = Loss coefficient for sudden increase in velocity.
K_L = Loss coefficient for turning a right angle.
$L\,d$ = Distance from division point to balance point, discharge side.
$L\,e$ = Distance from end-bell to balance point.
$L\,i$ = Distance from division point to balance point, intake side.
$P\,e$ = Pressure in end-bell.
$P\,i$ = Pressure in the intake chamber.
S = Cross sectional area of stator vents at the minimum section per unit length axially.
v_0 = Velocity in gap at division points.
v_e = Velocity in gap at end-bell end.
V = Velocity in stator vents at minimum section.
x = Variable distance from division point, intake side.
y = Variable distance from division point, discharge side.

These equations assume that we know the balance points, *i. e.*, the points in the air-gap when the velocity is zero. These points, which we have called "balance points" are determined by the following conditions,

1. The pressure drop for all paths must be the same.
2. The vent duct velocities at the balance point must be the same when computed for the two parallel circuits which meet at that point.

On account of the transcendental form of the equations, they cannot be solved simultaneously to find the values of $L\,i$ and $L\,d$ (*i. e.*, the balance points). Consequently, a trial and error method must be used for finding them.

The velocities as calculated from these equations were checked against test results for a large number of tests. The results checked against included a large number of tests on the model described in this paper, tests on the model described in the 1924 paper and tests on actual machines. In every case the agreement was found to be satisfactory. Figs. 12, 13 and 14 show the agreement for three of these tests.

CORRESPONDENCE

HIGHWAY LIGHTING

Editor, A. I. E. E. Journal,

I am much interested in your article on Page 24, entitled, "One Genuine Method of Solving The Automobile Headlight Problem."

Ten years' ago, I made a suggestion of scientifically illuminating the highways, which suggestion was much laughed at. It seems to me that most of the light on our highways and even on our boulevards in the city, is wasted by being up in the air. It seems to me that the primary purpose of illuminating a highway, is to illuminate the road itself, and that it does not matter whether or not anything above the road is illuminated.

My suggestion is that along the sides of the highways weather-proof lights, down low like footlights, be installed to thoroughly flood the highway without any light at all coming direct in the eyes of the motorist or even the pedestrian. That is, these lights would be installed low and so shaded that a highway would look like one broad ribbon of light.

If this were done, no head lights at all would be needed on any automobiles and all that would be necessary would be small pilot lights and a tail light, sufficient only to indicate the presence of the car. What do you think of this?

TALIAFERRO MILTON

NEW POWER PROGRAM IN GREAT BRITAIN

The new electrical power program of Great Britain, outlined by the Prime Minister, will be presented to Parliament during the coming session. This electricity bill, if passed, will be of great interest to the country as a whole, and will vitally affect its industries.

The main objects of the bill are the standardization of the frequency, at an estimated cost of £10,000,000; the laying of interconnecting cables between industrial areas; the reduction of the number of generating stations from 584 (at present) to 60; and the lowering of rates for electric current.

NATIONAL POWER BOARD TO DETERMINE POLICY

The plan outlined by the Prime Minister includes the creation of a national power board which will deal with matters of policy. The present electrical commissioners are to continue as technical advisors with particular reference to standardization and unification work now in progress, which, owing to the increased power granted, will be expedited. One result has been a rise in electrical shares on the exchange.

The sites for the new generating stations will, as far as possible, be on rivers and canals. It is estimated that it will take 15 years to develop this project and that ultimately the annual consumption of electricity in the United Kingdom will be raised to at least 500 kilowatt-hours per capita.

The Magnetic Hysteresis Curve

BY HANS LIPPELT[1]

Member, A. I. E. E.

Synopsis.—An analysis of the phenomena of hysteresis is ...nted in the paper which introduces the conception of a reactive ...mponent and a dissipative component of the counteracting force, ...ch appears when magnetizeable material is subjected to a magnetizing force. Using this conception, equations and curves are developed for the hysteresis curve, for the various components and for the hysteresis loss. The loss is shown to depend directly on the dissipative component.

I. Nature of the Problem

1. The purpose of this paper is an analytical study of the fundamental character of magnetic hysteresis with a view to formulating, if possible, reliable mathematical terms in convenient form.

Foremost among the historical works along this line is that by Hopkinson (giving a theory of the magnetic circuit), which was well augmented by Fröhlich as published in the *Elektrotechnische Zeitschrift* of 1881,

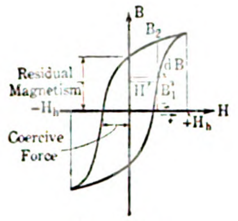

Fig. 1

pages 90 and 139; and a treatise by Professor Kennelly printed in the Transactions of the A. I. E. E. 1891, page 485.

The most familiar representation of magnetic hysteresis is the well-known loop, as shown in Fig. 1, in which the salient features are duly emphasized.

2. *Nature of Forces Involved in the Process of Magnetization.* As will be explained, the process of magnetization of the so-called magnetic metals and alloys seems to involve three forces.

(a). Magnetizing force H, which tends to produce magnetic induction in the material in the direction of H.

(b). Reactive force R, which tends to demagnetize the material, that is, to reduce the induction to zero. It seems to be a force of the nature of internal elastic stress, similar to a reactive tension.

(c). Dissipative force D, which opposes *changes* of magnetic induction. It seems to be a force of the nature of (molecular) friction and tends to maintain the material in the state of magnetization in which it happens to be at the moment.

The first force, H, is of external origin, being produced usually by an electric current.

When the magnetic circuit contains an iron core the total flux per sq. cm. of cross-section is

$$B = H + 4\,\pi\,I = H + \beta \qquad (1)$$

where $\beta = 4\,\pi\,I = B - H$ is called the intrinsic induction in the iron.

To better illustrate the relations, let us assume that a magnetic hysteresis curve $B_1\ B_2$ has been determined by experiment, Fig. 2. Its course is indicated by dotted lines, $B_1\ B_2$. True to definition corresponding curves β_1 and β_2 have been produced by subtracting from the ordinates of $B_1\ B_2$ the corresponding abscissas, H.

3. *Manifestation and Character of Forces R and D.* That the external force H cannot be the only force entering into the process of magnetization may readily be understood from the axiom of physics, according to which any action entails a reaction. H represents the action in this case and two forces, R and D, the reaction. That becomes particularly evident from observations which are common to the well-known experiment of magnetizing iron by an electric current, and which it becomes necessary to again review.

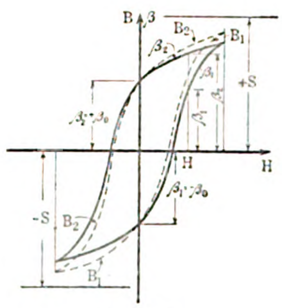

Fig. 2

(a). When an electric current flows through the spool, a magnetic field H is created within its cross-sectional area. This field H acts upon the iron core and causes it to become traversed by a strong magnetic flux β of the same direction as H. The iron will hold that flux as long as the magnetic field H exists. This indicates a tendency of H to produce (impress) induction in the iron in the direction in which it operates.

(b). Now if we interrupt the current, the magnetic field H will disappear and with it most of the magnetism β of the iron. This abatement of magnetism can be explained by the assumption of an internal

1. Thomas E. Murray, Inc., 55 Duane Street, New York City.

Abridgment of paper presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies available upon request.

force R, which tends to drive the magnetic flux β out of the iron, as an elastic reaction (tension) would do. Therefore, R is of opposite sign to H.

(c). If we put the current on again, there will reappear both the field H and the magnetism β. With the presence of R conceded under b, we will now have to broaden our conclusion (a) to the extent that the field H causes magnetism to be impressed upon the iron even against the opposing force R. Since the degree of magnetization is the same for the same recurring field H, it is likely that R depends on the degree of magnetization, the latter reaching the steady state, when its sequel, the tension R, has likewise reached its original value. On the other hand, if R were not present, magnetization should be expected to rise to any abnormal value.

(d). If we increase (or decrease) the field H over (or under) the value obtained under c, it will be followed by a strengthening (or weakening) of β. β coming in each case to a steady state when its associate reaction R has adjusted itself to the new value of H. Therefore, R is surely a function of the quantity β

$$R = F(\beta)$$

If no other forces were contingent upon the process, there should be $R = -H$, because in physics the reaction is always equal and opposite to the action. This also fixes the dimension of R to be the same as that of H, namely $C^{-\frac{1}{2}} G^{\frac{1}{2}} S^{-1}$.

It will be shown however, that these two forces R and H do not suffice to explain all the magnetic states, nor any one of them completely. A third force will exhibit itself when existing conditions are scrutinized more thoroughly.

(e). If the flow of current be interrupted altogether, it will be found that also, most of the magnetism has been lost but not all of it. Residual magnetism, either $\beta_2 = +\beta_0$ or $\beta_1 = -\beta_0$ has been retained in the iron, particularly so when the material under test is hardened steel (Figs. 1 and 2).

Consistent with the above reasoning the presence of that residual magnetism β_0 ought to entail a residual reaction R_0. Since the field $H = 0$ (when no current flows), there would now be no force counteracting the reaction R_0 and all the magnetism should disappear from the iron. As it does not disappear, we are compelled to admit the existence of another, a second internal force. We recognize at once one of the characteristics of this new force; namely, it tends to *resist changes* in the magnetic state existing in the iron at the time, inasmuch as the residual magnetism continues to exist in a permanent magnet. The nature of that force, therefore, seems to be that of a friction. It will be designated by the letter D.

When the field H [illegible]'s friction has the special value D_0 and bala[illegible] up against the internal tension R[illegible] Thus

$$D_0 + R_0 = 0$$

and the coincident state of magnetization is expressed by one of the two equations

$$\text{either } \beta_2 = +\beta_0 \text{ or } \beta_1 = -\beta_0$$

as per Fig. 2.

The fact that for any other value of H we observe likewise two values of β (Fig. 2) is proof enough of the magnetic friction D obtaining for all states of magnetization. D manifests itself particularly by the difference between β_1 and β_2 where the changes of β are large as referred to unit changes of H (*e. g.*, where the β curves are steep), and abates where they are small. Hence

$$D = F_1(\Delta\beta)$$

To amplify this reasoning, let us remember that for rapid changes of β (*e. g.*, $\Delta\beta$ = large), the reaction R also changes rapidly. Since H was assumed to change in unit steps only, D must necessarily make up for the rapid changes of R, which in turn conform to rapid changes of β, that is to $\Delta\beta$. This argument is also consistent with the force D being a "resisting" force and for this very reason D is negative, when $\Delta\beta$ is positive and vice versa.

It is obvious that the dimension of D is likewise $C^{-\frac{1}{2}} G^{\frac{1}{2}} S^{-1}$ because only forces of like character can enter into a play of action and reaction.

This force D will after further study reveal itself as the actual cause of hysteresis.

Having conceded three forces H, R and D to govern the process of magnetization, we were able to explain all and any conditions observed to exist in a magnetized material. To do that *all* of these *three forces* were *necessary*, but it is also evident that they are sufficient. The *magnetization* (β), however, when in the steady state depends on the equilibrium of those three forces. That is mathematically expressed in general by

$$H + D + R = 0 \quad (2)$$

and when applied to the ascending branch β_1 by

$$H_1 + D_1 + R_1 = 0 \quad (3)$$

and to the descending branch β_2 by

$$H_2 + D_2 + R_2 = 0 \quad (4)$$

Our problem was outlined in the first paragraph of Section I. It amounts, among others, to finding a formula $\beta = f(H)$, expressing in explicit terms the relation between the field H and the magnetization β. After what was said, this problem resolves itself now into two separate problems, *i. e.*, to determine, primarily the equations for R and D as functions of H; and in conjunction therewith functions expressing R and D in terms of β.

II. Equation of Reactive Force $R = F(\beta)$

4. *Relation of R to β near Saturation.* It is known that the magnetization β of a magnetizable material can rise only to its saturation value S as a limiting value. When magnetization is approaching saturation, it will do so gradually and $\Delta\beta$ is small for large changes of H. Small variation of β, however, entails a negligible

force D and such a state of affairs in connection with equation (2) will be used as a guide for finding a mathematical relation between R and β.

5. *Law of Magnetization near Saturation.* As is well known, the curve of β plotted against the field intensity H as abscissa approaches, for large values of H, an asymptote, which runs parallel to the H-axis at a distance S = maximum value of β, Fig. 3.

That figure confirms the statement made in the foregoing paragraph (4) that β increases only little for large

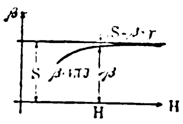

FIG. 3

increments of H. In other words the difference

$$S - \beta = \gamma$$

decreases rather slowly, because $\Delta\beta$ is small and so is the magnetic friction D.

Since the large external action H *must* meet a large internal reaction, it becomes necessary to ascribe a *large* value to the internal magnetic tension R. This quantitative relation becomes very plausible, when comparing the magnetism impressed upon the iron with an elastic medium being heavily compressed in a suitable container. (See Appendix I).

A law that is true in physics for compressed elastic mediums may apply also in our case of magnetism being impressed under similar symptoms upon suitable materials. That law applied will fix the internal reactive tension R as being inversely proportional to the capacity of the material for further magnetization. If $+ S$ is the saturation value and β the amount of magnetism impressed by a positive field $+ H$, the capacity for further magnetization is

$$\gamma = S - \beta$$

(See Fig. 3.) Under our assumption, the reactive component R would be expressed by

$$R_+ = - \frac{K}{S - \beta} = - \frac{K}{\gamma} \qquad (5)$$

where K is a factor of proportionality depending on the units selected for β and R. R_+ has been written to refer it to positive values of H and β.

In formula (5) the constant $-K$ is that reactive tension which exists when $\gamma = 1$.

We had to place the minus sign before the right hand side of formula (5) because R_+ is of a direction opposite to H (and also β), which we had assumed positive.

6. *Applying formula $R_+ = - \dfrac{K}{\gamma}$ to the whole range of magnetization.* This relation (5) applies, strictly speaking only to the range near positive saturation. So long as the contrary is not proven, it is well worth while to try out its alleged validity for the whole range of magnetization and study the effect. Such an initial study of R, without paying attention to D, appears all the more justified, because R is a force depending on the degree of magnetization, while D depends primarily on the quality of the material.

In order to better understand this relation between β and R_+, a curve has been drawn up (Fig. 4) corresponding to formula 5. It proves to be an equilateral hyperbola, whose one axis coincides with the axis of abscissas β, while the other is parallel to the axis of ordinates at a distance equal to $+ S$, *e g.*, the saturation value of β.

For values of β approaching $+ S$, R_+ grows infinitely large and is of negative sign. For smaller values of β the numerical value of R_+ decreases first rapidly then slowly until it attains

$$\text{when } \beta = 0 \text{ a value } R_+ = - \frac{K}{S}$$

According to our curve, Fig. 4, R_- continues to have negative values and does not become zero until

$$\beta = - \infty$$

Returning now for a moment to Fig. 2, we notice that for heavy negative values of field intensity H, the value of β approaches a negative maximum $- S$. Formula 5 and curve Fig. 4, both yield for this value of $\beta = - S$

$$R_+ = - \frac{K}{+ S - (- S)} = - \frac{K}{2 S}$$

while we should expect an infinitely large value for R in conformity with our previous reasoning.

7. *Adapting the law of reactive tension R to negative magnetization.* This discrepancy of the quantitative relation between R and β, which became evident with negative magnetization, may easily be taken care of by

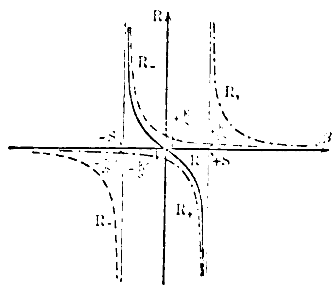

FIG. 4

repeating, for that condition, the application of the law of stressed elastic mediums.

Similar to the process carried out in chapter (5) we write now for strong negative magnetization.

$$R_- = - \frac{K}{(- S) - \beta} = + \frac{K}{S + \beta} \qquad (6)$$

Formula (6) as well as formula (5) represents an equilateral hyperbola (Fig. 4), and in this curve the

same discrepancy as that encountered above is here confronted in reversed form for $\beta = + S$.

8. *Modification of the Law of Inverse Proportionality.* The validity of each individual formula (5) and (6) to the limited zone of magnetization near positive or negative saturation respectively renders both of them unsuitable for general use. The situation is aggravated by the duplicity of value for R when $\beta = 0$, as given above $\left(R_+ = - \dfrac{K}{S} \text{ and } R_- = + \dfrac{K}{S} \right)$.

Even if it were conceded that formula (5) holds for positive magnetization and formula (6) for negative magnetization, the discontinuity and an abrupt change from $- \dfrac{K}{S}$ to $+ \dfrac{K}{S}$ at zero magnetization is not compatible with the behavior of elastic mediums, which had been referred to for comparison (see Appendix I).

However, continuity is a necessary prerequisite and that can readily be obtained by admitting the simultaneous validity of both formulas (5) and (6). Such a step finds its mathematical expression in the following form.

$$R = R_+ + R_- = - \frac{K}{S - \beta} + \frac{K}{S + \beta}$$

or

$$R = - \frac{2 K \beta}{S^2 - \beta^2} \qquad (7)$$

Formula (7) is the sum of the two terms 5 and 6 and so is curve R in Fig. 4 the composite curve of the individual curves R_- and R_+.

The new curve has actually three branches, but the two external ones, which belong to abscissas whose numerical values are larger than S, are at present of no utility. Our present consideration shall be limited to the range between $+ S$ and $- S$.

Of the unknown quantities contained in equations (3) and (4) two may now be considered known, namely

$$R_1 = - \frac{2 K \beta_1}{S^2 - \beta_1^2} \qquad (9)$$

$$R_2 = - \frac{2 K \beta_2}{S^2 - \beta_2^2} \qquad (10)$$

9. *Determination of Constants S and K.* One of these constants, S, depends surely on the magnetic quality of the material under consideration. Experiments have shown that.

Whether and to what extent K depends on the material is still to be proven by tests. Primarily K is a special value of magnetic tension.

From a few coordinated values of β near saturation, the saturation value S itself can be found by extrapolation with sufficient accuracy.

The same test readings of H and β will lend themselves to the determination of the constant K, when recourse is had to formula (7) and $- H$ is substituted for R.

Another method for determining K is explained below in connection with the study of force D.

10. *Conclusions in Regard to reactive Tension R.* We have seen that: (*a*). The reactive component R of the internal counteracting force is a force of the nature of elastic recoil. (*b*). This force R is caused by and is a mathematical function of the magnetic induction β. (*c*). The relation of R to β may be expressed hypothetically by the equation $R = - \dfrac{2 K \beta}{S^2 - \beta^2}$ (*d*). Although the reliability of this equation has been demonstrated by experimental data pertaining to but one material, its plausibility can be enhanced by the agreement of its corollaries with known facts and theories. (See Appendix I).

(*e*.) For values of β near saturation, the equation reduces itself to the form $R = - \dfrac{K}{\gamma}$ (Appendix I).

Under these same limitations Fröhlich's law is reduced to the form $H = \dfrac{K}{\gamma}$. It follows that $R + H = 0$ and that magnetic friction D and hysteresis are negligible near saturation. This conclusion is in harmony with known facts.

(*f*). For small values of β the equation reduces itself to the form $R = - \dfrac{2 K}{S^2} \times \beta$ which makes it very analogous to Hooke's Law for elastic bodies. (Appendix I).

III. Equation of Dissipative Force D

11. *Review and Aspect.* The ultimate object before the author was the establishment of an equation which relates the magnetization β to the field H. Our basic equation (2) harbors the solution of the problem in so far as it ties into a law three magnetic forces which in turn are related to β and H.

The force R proved to be a force having the magnetization β as its cause and being quantitatively related thereto as per equation (7).

The dissipative force D, however, depends on the magnetic quality of the material magnetized. To study the character of this force D and its magnitude necessitates, therefore, a recourse to actual test of suitable materials.

Should we succeed in developing for this force D mathematical terms containing D as a function of H or β, the analytical representation of the magnetic hysteresis curve would then become possible.

(12). *Exploitation of Experimental Data.* For the purpose of investigating to what laws the internal

friction D (*i. e.*, D_1 and D_2) is subject, we employ a hysteresis curve that shows clearly the properties in question. By experiment the writer has determined such a curve for a material known as Hardened Tungsten Steel. The β-curve for this material is shown in Fig. 5.

The method employed was the step-by-step method applied to Hopkinson's Divided Bar, using also a ballistic galvanometer.

The curve is composed of two branches, β_1 and β_2. Only the β_2-branch has been plotted from observed data, because the observed results for the β_1-branch may contain errors of observation. Ascertainment of degree of accuracy is not possible now. The β_1-branch shown is a copy of β_2-branch by virtue of symmetry.

13. *Numerical Values for K and S.* In order now to apply equations (9) and (10) to our curve, the values of S and K ought to be known.

From the curvature of β curve near its highest ordinates (Fig. 5), $S = 16000$ is estimated by graphical extrapolation.

To determine K, curves were plotted first taking K as an arbitrary constant which was later corrected as will be explained. For plotting these curves equations (9) and (10), $R = -\dfrac{2K\beta}{S^2 - \beta^2}$, were made use of. By their aid $+R$ could be plotted as a function of β (similar to Fig. 4). However, it was found more useful to plot $-R$ as a function of H. The hysteresis curve, Fig. 5, gives values of H corresponding to different values of β and by use of these values, taken from the hysteresis curve, it was possible to plot $-R$ as a function of H.

The curves for $-R_1$ and $-R_2$ so plotted are shown in Fig. 5. This Fig. 5, however, shows the final corrected curves which were not obtained until the correct value of K had been determined.

As already mentioned, K was first given an arbitrary value and the curves for $-R_1$ and $-R_2$ were plotted against H. An inspection of these original curves showed that for large values of H they approached the straight line $H_{ordinate} = H_{abscissa}$. Knowing this it was possible to plot the curves to their true scale as shown in Fig. 5. Also the true value of K could be determined and it was found to be $K = 0.5682 \times 10^6$ for the sample tested.

14. *Curves for D_1 and D_2 as depending on Field H. Permanent Magnets.* As $-R = (H + D)$ it is possible to get values of D from the $-R$ curves in Fig. 5. This was done and curves for D_1 and D_2 as functions of H were accordingly plotted in Fig. 5. $(-R - H = D)$.

Observe that the ordinates of D_1 are negative, while those of D_2 are positive.

Of special interest is the maximum value, which—referring to curve D_1—occurs for

$$H_1 = \text{approximately } +36\, C^{-1/2} G^{1/2} S^{-1}$$
$$D_1 = \text{approximately } -70\, C^{-1/2} G^{1/2} S^{-1}$$

Furthermore for

$$H_1 = 0 \text{ we have } \begin{cases} D_1 = -61.5\, C^{-1/2} G^{1/2} S^{-1} \\ \beta_1 = -9230\, C^{-1/2} G^{1/2} S^{-1} \\ +R_1 = +61.5\, C^{-1/2} G^{1/2} S^{-1} \end{cases}$$

When no external field H exists the two internal forces D_1 and R_1 (also D_2 and R_2) are numerically equal, but of opposite sign and therefore balance one another.

If we now go along curve β_1 (Fig. 5) from value -9230 units, where $H = 0$ to -8000, which represents a decrease in the magnetic flux, we get for this lower state of magnetization

$$R_1 = +47.4\, C^{-1/2} G^{1/2} S^{-1}$$
$$D_1 = -68.4\, C^{-1/2} G^{1/2} S^{-1}$$
$$H_1 = +21.\ \ C^{-1/2} G^{1/2} S^{-1}$$

This means for this decrease in flux the internal friction D_1 has increased and is stronger than the internal tension R_1, which has decreased. Therefore,

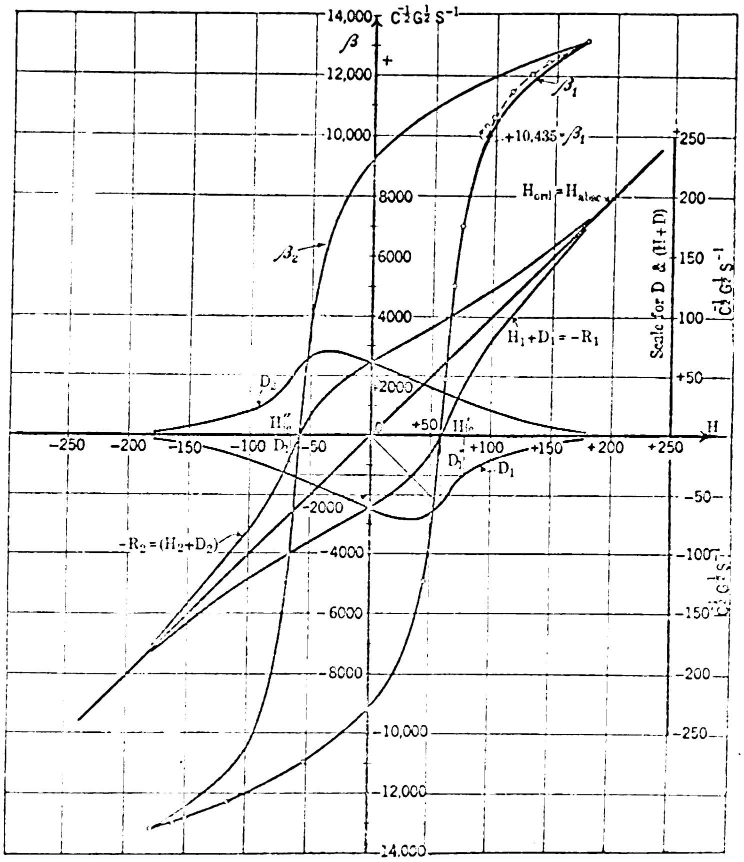

FIG. 5

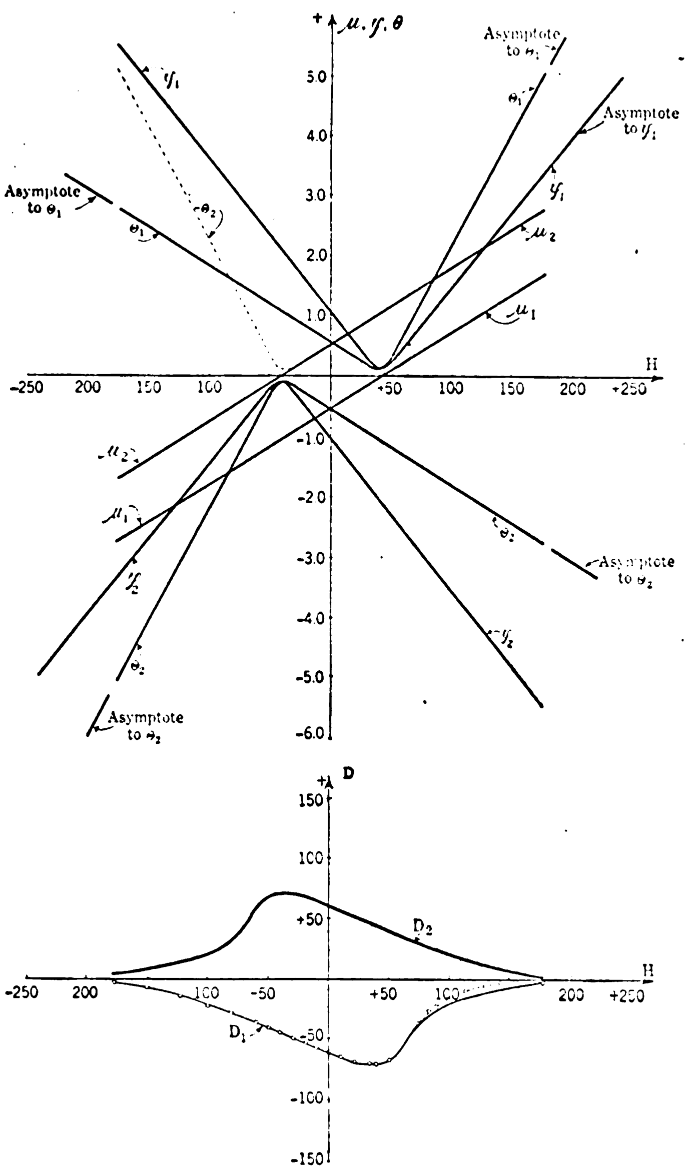
without the addition of $H_1 = +21$ to force R_1, the magnetism within the iron could not diminish. This fact explains the phenomenon of permanent magnets. We may put it in this way.

"In permanent magnets magnetic friction and reactive tension are equal. For diminishing flux the fric-

tion increases, while the tension decreases. Therefore, the flux *cannot* decrease as a result of the reactive tension."

Also for other small and increasing values of H_1 the magnetic friction is both increasing and greater than the reactive magnetic tension, being smaller and diminishing. Such conditions will obtain until D_1



Figs. 6-7

reaches its maximum value. After that, both D_1 and R_1 are decreasing, and, as a sequel, the magnetization β_1 of the steel does rapidly decline.

For $\beta = 0$, we have $\begin{cases} -D_1 = +H_1 = \text{approx.} + 59 = \text{the coercive force} \\ R_1 = 0. \end{cases}$

For this condition magnetic friction and field intensity counteract and cancel one another, while the magnetic tension is zero.

For further rising field strength the magnetization β_1 increases rapidly at reversed (positive) values, owing to a rapid receding of D_1. The increase in flux, however, will soon cause R_1 to rise and the increments in magnetization, as referred to constant increments in field intensity, become smaller and smaller the more we approach the highest value of β_1. At the same time the magnetic friction D_1 converges towards the limit zero, while the reactive magnetic tension R_1 is striving towards an infinitely large value.

15. *Mathematical Relation of D and H.* After having analyzed in a general way the curves plotted from observed data, the problem remains to find mathematical terms, expressing the intrinsic and mutual relations of all the forces involved and of the flux.

As regards the D curves discussed above it was possible to get a mathematical relation between D and H. The method of deriving this relation is given in Appendix II. It was found that the graphical curves D_1 and D_2 are closely satisfied by the following equations.

$$D_1 = -\frac{A}{\cosh \theta_1} \tag{11}$$

with

$$\left.\begin{aligned} \theta_1 &= u_1 + \varphi_1 \\ u_1 &= + c\,(H_1 - f) \\ \varphi_1 &= + q\sqrt{p + u_1^2} \end{aligned}\right\} \tag{12}$$

and

$$D_2 = +\frac{A}{\cosh \theta_2} \tag{13}$$

with

$$\left.\begin{aligned} \theta_2 &= u_2 + \varphi_2 \\ u_2 &= + c\,(H_2 + f) \\ \varphi_2 &= - q\sqrt{p + u_2^2} \end{aligned}\right\} \tag{14}$$

For the sample tested the constants are as follows $A = 70.061\ C^{-1/2}\ G^{1/2}\ S^{-1}$; $f = 42$; $c = 0.012515$; $p = 0.003255$; $q = 2$

In connection with these equations the respective curves have been computed and drawn up in Figs. 6 and 7. Fig. 6 shows the graphs for u_1, φ_1, θ_1 and u_2, φ_2, θ_2, while in Fig. 7 a copy is given of the D_1 and D_2 curves as plotted from *observed* results.

In curve D_1 a few small circles indicate such points of D_1 curve as have been computed by formula (11).

IV. Magnetic Flux

16. *Relation of β to R.* By solving equations (9) and (10) for β_1 and β_2 respectively, we get in general

$$\beta = + \frac{K}{R} - \frac{1}{R}\sqrt{K^2 + R^2 \times S^2} \tag{15}$$

Values for β_1 and β_2 have likewise been computed. Between observed and computed values of β_1 and β_2 an agreement of even better degree than for D_1 (Fig. 7) is apparent in Fig. 5. And such better agreement is due to the fact that quantity $R = -(H + D)$ enters into formula (15). If D were not quite correct, the error would not manifest itself any more, than D partakes in the sum $R = -(H + D)$.

Deviation between observed and computed values is indicated for the β_1 branch only by a dotted line Fig. 5).

However, for $H_1 = +93.4$ the *observed* value $\beta_1 = +10435$ has been plotted and it falls very close to the computed (dotted) line. The above formulas may, therefore, be considered as being correct to satisfy any reasonable demands.

The term on the right hand side of formula (15) permits of a nice transformation. Move the product $R^2 S^2$ outside the square root and write:

$$\beta = S\left[\frac{K}{S\,R} - \sqrt{\left(\frac{K}{S \times R}\right)^2 + 1}\right]$$

By applying now the following substitution

$$\frac{K}{SR} = \sinh\psi \text{ or } \psi = \sinh^{-1}\frac{K}{SR} \qquad (16)$$

our formula will turn into

$$\beta = \pm S\left[\sinh\psi - \cosh\psi\right] = \mp S \times e^{-\psi} = \mp S\frac{1}{e^{\mp\psi}} \qquad (17)$$

For the exponential form we have

$e = 2.7188$ the base of hyperbolic logarithms
ψ = a positive hyperbolic angle
$-$ sign applies when R is positive (β = negative)
$+$ sign applies when R is negative (β = positive)

These relations are represented graphically by full line curve in Fig. 4.

By substituting in formula (15) for R the term $-(H + D)$, with D as per equations (11) and (13), β may be expressed in terms of H:

$$\beta = +\frac{K}{-\left(H + \dfrac{\mp A}{\cosh\theta}\right)} - \frac{1}{-\left(H + \dfrac{\mp A}{\cosh\theta}\right)} \times \sqrt{K^2 + \left(H + \frac{\mp A}{\cosh\theta}\right)^2 \times S^2} \qquad (18)$$

and this is the equation of the Hysteresis Curve.

V. Energy Loss and Other Relations

17. *Loss of Energy.* This problem of the hysteresis curve would not be completely answered without stating the so-called hysteresis loss.

As known, this loss in ergs is computed by (Fig. 1)

$$L = \frac{V}{4\pi}\overset{-H_h}{\underset{-H_h}{\mp\!\!\int}} H\,dB = 2\frac{V}{4\pi}\int_0^{-B_h}(H_1 - H_2)\,dB \;(C^2 G S^{-2}) \qquad (19)$$

whereby V is the volume of the magnetized material in cubic-centimeters and $\overset{-H_h}{\underset{-H_h}{\mp\!\!\int}}$ indicates that we have to integrate between the limits from $-H_h$ to $+H_h$ and back to $-H_h$. H_h is the highest field intensity attained.

Observing now equation (1) our integral dissolves into

$$L = \frac{V}{4\pi}\overset{-H_h}{\underset{-H_h}{\mp\!\!\int}} H\,dH + \frac{V}{4\pi}\overset{-H_h}{\underset{-H_h}{\mp\!\!\int}} H\,d\beta$$

The value of the first of those two integrals is nil, leaving for the loss

$$L = \frac{V}{4\pi}\overset{-H_h}{\underset{-H_h}{\mp\!\!\int}} H\,d\beta = \frac{V}{4\pi} \times I \qquad (20)$$

$I = \overset{-H_h}{\underset{-H_h}{\mp\!\!\int}} H\,d\beta$ represents the area within the loop $\beta_1\,\beta_2$ of Fig. 2.

Designating the highest value that β attains by β_h and by further transformation we get

$$I = -2\left\{\int_{\beta_1=0}^{\beta_1=\beta_h}\beta_1\,dH_1 - \int_{\beta_2=0}^{\beta_2=\beta_h}\beta_2\,dH_2\right\} \qquad (21)$$

The following equations (15), (9), (10), (3), (4), made use of in the order named, will permit to express these integrals in terms of H, and eventually yield the loss thus:

$$L = -\frac{V}{2\pi}\Bigg\{+\int_{+H_0}^{+H}\left(-\frac{K\cosh\theta_1}{H_1\cosh\theta_1 - A} + \frac{1}{H_1\cosh\theta_1 - A}\times\sqrt{K^2\cosh^2\theta_1 + (H_1\cosh\theta_1 - A)^2 S^2}\right)d\,H_1$$

$$-\int_{-H_0}^{+H_h}\left(-\frac{K\cosh\theta_2}{H_2\cosh\theta_2 + A} + \frac{1}{H_2\cosh\theta_2 + A}\times\sqrt{K^2\cosh^2\theta_2 + (H_2\cosh\theta_2 + A)^2 \times S^2}\right)d\,H_2\Bigg\} \qquad (22)$$

with θ_1 and θ_2 as per equations (12) and (14) and $H = +H_0$ when $\beta_1 = 0$ $H = -H_0$ when $\beta_2 = 0$. highest value attained by H is H_h.

Similarly

$$I = -2\int_0^{\beta h}\beta\,(-\,d\,D_1 + d\,D_2) = -\,2\int_0^{\beta h}\beta\,d\,(-D_1 + D_2) \qquad (24)$$

and the loss

$$L = -\frac{V}{4\pi}2\int_0^{\beta h}\beta\,d(-D_1 + D_2) = -\frac{V}{2\pi}\int_0^{\beta h}\beta d(-D_1 + D_2) \qquad (25)$$

also

$$L = +2\frac{V}{4\pi}\int_0^{\beta h}(-\,D_1 + D_2)\,d\beta \qquad (23)$$

The solution of this latter integral requires D_1 and D_2 or $(-\,D_1 + D_2)$ as a function of β. That will be accomplished in the next chapter.

But it may be remarked here that the differential

of energy loss, according to formula (28), reveals itself as the product of the magnetic friction times the change in the flux, to wit:—"friction times magnetic current." Formula (28) in this form $\frac{d\,L}{d\,t} = \frac{V}{2\,\pi}$ $(-D_1 + D_2)\frac{\partial\beta}{\partial t}$ expresses the "Hysteresis Power

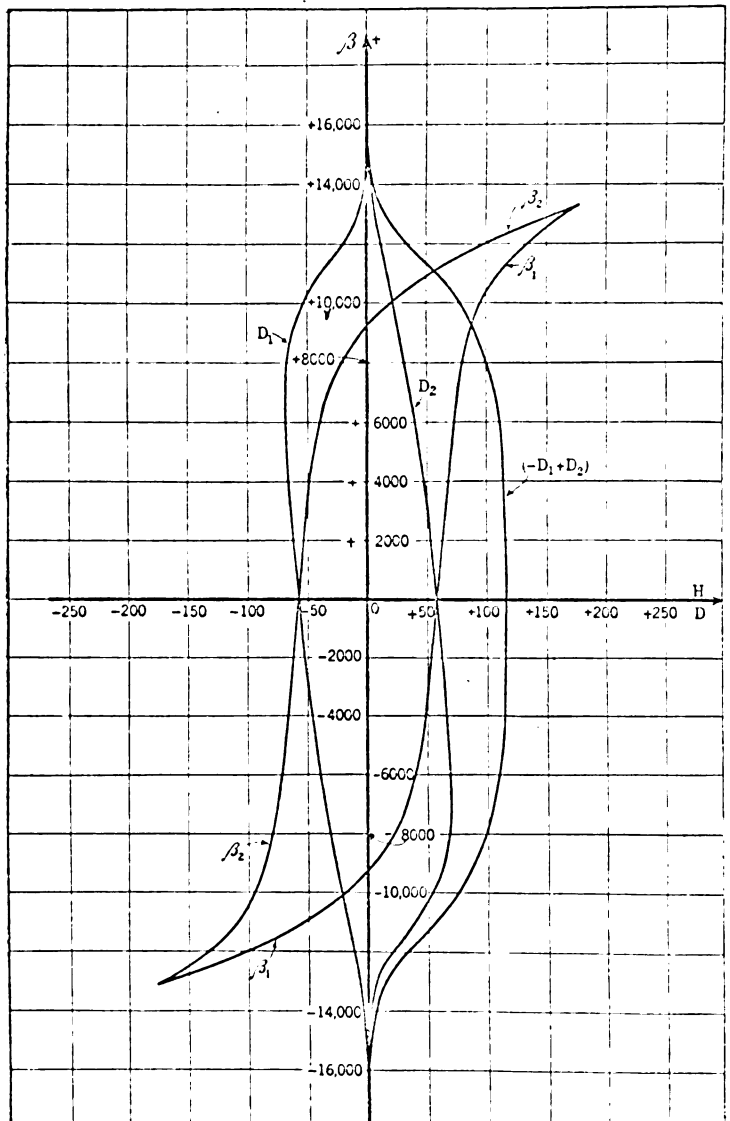


FIG. 8—MAGNETIC HYSTERESIS CURV :

Loss" as being proportional to the product "Force of Friction times Magnetic Current."

12. *Magnetic Friction D as a function of induced flux β.* Fig. 8 shows the curves of magnetic friction D_1 and D_2 over the induced flux β as abscissas.

These curves D_1 and D_2 were derived by transposing the ordinates D_1 and D_2 from their H abscissas to such β abscissas as are coordinated to the H abscissas.

No matter between what limits the magnetic cycle occurs, for $H = \pm\infty$ the values of D_1 and D_2 are zero and those of β_1 and β_2 are $\pm S$.

Consequently our two curves D_1 and D_2 must have zero points for the abscissas $+S$ and $-S$. This enables us to consider D_1 and D_2 as two half waves of two combined sine and cosine series with higher harmonics.

Referring now to curve D_1 particularly, its equation has been determined on that basis, using a method developed and described by Prof. Runge,[2] namely

$$D_1 = 10^{-3} \times S \sum \left(b_n \sin n\frac{\pi}{2}\frac{\beta_1}{S} + a_n \cos n\frac{\pi}{2}\frac{\beta_1}{S}\right) \tag{29}$$

and

$$D_2 = 10^{-5}\,S \sum \left(b_n \sin n\frac{\pi}{2}\frac{\beta_2}{S} - a_n \cos n\frac{\pi}{2}\frac{\beta_2}{S}\right) \tag{30}$$

with

n =	1	3	5	7	9	11	13	15
b_n =	+0.612	+0.606	−0.2185	−0.702	+0.0976	−0.030	+0.0219	−0.0202
a_n =	−3.89	+0.014	+0.345	−0.195	−0.0528	+0.020	−0.015	−0.004

19. *The Dissipated Energy (Numerical).* By virtue of equations (28), (29) and (30), we have for the loss

$$L = \frac{V}{2\,\pi}\int_0^{\beta_h}(-D_1 + D_2)\,d\beta \tag{31}$$

In forming the difference $(-D_1 + D_2)$ all sine members disappear and we get

$$\frac{L}{V} = -10^{-3} \times \frac{2}{\pi^2}S^2 \times \lambda = -194100 \text{ ergs per cu. cm.} \tag{32}$$

wherein

$$\lambda = \left[\sum \frac{\text{const}}{n}\sin n\frac{\pi}{2}\frac{\beta}{S}\right]_0^{\beta_h} = 3.7423 \tag{33}$$

$$\beta_h = \text{approx. } 13183;\ S = 16000$$

$$n = 1, 2, 3 \ldots\ldots 15$$

The only dimensional quantity on the right side of formula (32) is S^2 whose dimension in the $C\,G\,S$— system is $(C^{-1/2}\,G^{1/2}\,S^{-1})^2 = C^{-1}\,G\,S^{-2}$ = ergrs. per cu. cm., what it ought to be. In that way we get a confirmation that our theory and results are right.

According to the well-known Steinmetz formula, the hysteresis loss is computed by

$$\eta \times B_{max}^{1.6} \text{ in ergs per cu. cm.} \tag{34}$$

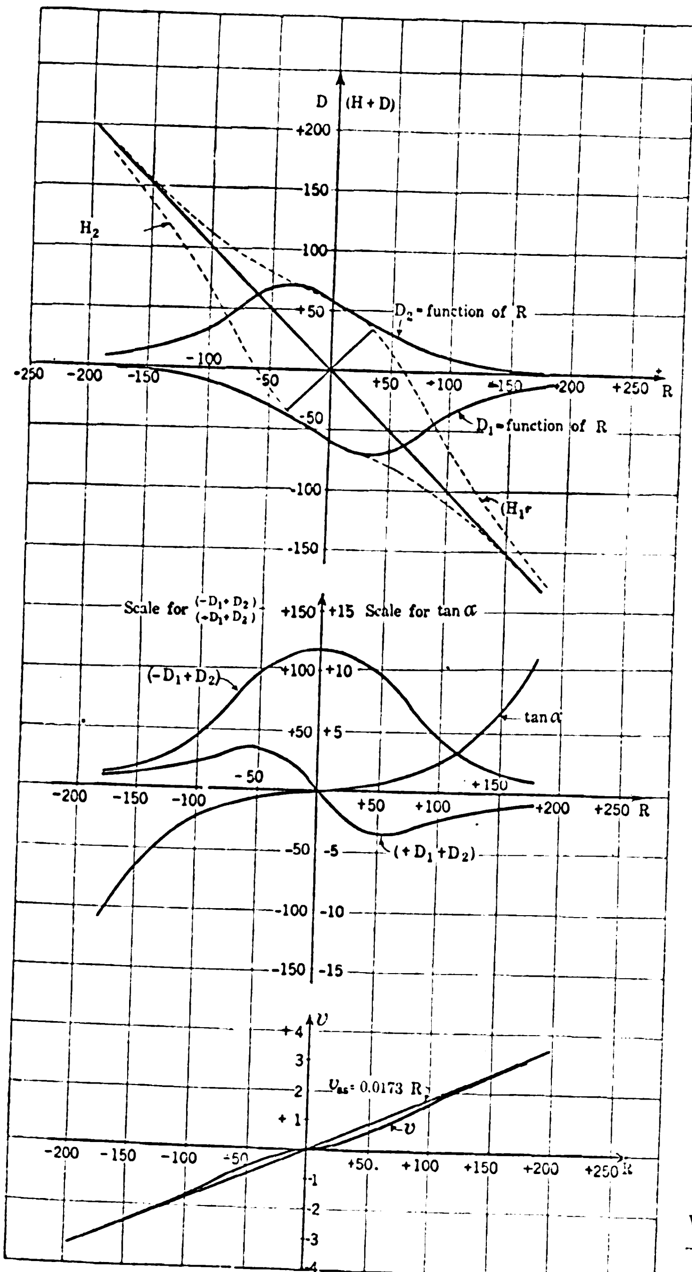
2. See *Electrotechnische Zeitschrift*, 1905, p. 247. C. Runge, "*Theorie & Praxis der Reihen*" Goshen at Leipsig, Germany.

which, when compared with our results, will ultimately net $\left(\text{neglecting } \frac{H_h}{S} = 0.011\right)$:—

$$\eta = 0.04862$$

and

$$\lambda = \frac{1000\,\eta \times \pi^2}{2}\left(\frac{\beta_h}{S}\right)^{1.6} \times S^{-2/5} \qquad (36)$$



FIGS. 9–10–11

Further experiments should show to what extent this formula is correct.

Appendix III contains formulas which give the energy loss in explicit terms of the leading quantities.

20. *Magnetic Friction D as Function of Magnetic Tension.* Fig. 9 shows curves. For formulas see Appendix III.

21. *Loss of Energy in Terms of Flux β and Tension R.* Formulas and computations will be found in Appendix III. Pertinent curves are illustrated below Figs. 9, 10, 11.

VI. ALTERNATING CURRENT EXCITATION

23. *Sine Current.* In the case where an alternating current is used to furnish the magnetomotive force, the intensity of the magnetic field will be expressed by

$$H = H_h \times \sin\frac{2\,\pi}{T}\,t = \text{const} \times I_0 \sin\frac{2\,\pi}{T}\,t \qquad (37)$$

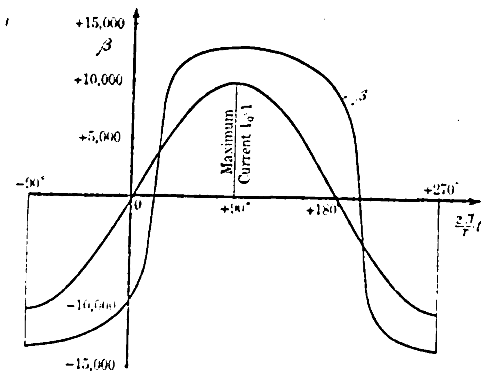


FIG. 12

while the curve for β contains higher harmonics as per Fig. 12 (for the sample tested).

$$\beta = S \times \sum c_n \sin\left(\frac{2\,\pi}{T}\,t + \omega_n\right) \qquad (39)$$

with

n =	1	3	5	7	9	11
C_n =	+0.9482	+0.2324	+0.1212	+0.07891	+0.05684	+0.09989
ω_n =	−8°26′	−61°7′	−106°28.4′	−151°48.6′	+163°3.6′	−102°23.6′

24. *Sine Voltage.* For the case of a sine voltage

$$E = E_0 \sin\frac{2\,\pi}{T}\,t$$

being applied to the windings around the magnetic material, the magnetic flux β and field H are illustrated in Fig. 13.

$$\beta = S \times \sum C_n \sin\left(\frac{2\,\pi}{T}\,t + \Omega_n\right) \qquad (41)$$

with

n =	1	3	5	7	9	11
C_n =	+0.8314	$+\frac{2.868}{1000}$	$+\frac{0.6956}{1000}$	$+\frac{0.069}{1000}$	$+\frac{0.08924}{1000}$	$+\frac{0.5953}{1000}$
Ω_n =	−90°14.8′	+82°35′	+60°37.9′	+94°56′	+176°0′	−161°38.4′

and

$$H = 177 \sum h_n \sin\left(\frac{2\,\pi}{T}\,t + \nu_n\right) \qquad (42)$$

with

n =	1	3	5	7	9	11
h_n =	+0.7559	−0.2592	−0.0629	−0.00624	−0.00806	−0.00538
ν_n =	−64°13.7′	+82°35′	+60°37.9′	+94°56′	+176°0′	−161°38.4′

VII. Applying the Theory

To show the ability of the new theory we shall now apply it to the well-known theory of Hopkinson's Magnetic Circuit, in conjunction with Professor Kennelly's paper on Reluctivity (TRANSACTIONS of the A. I. E. E. 1891, page 485.)

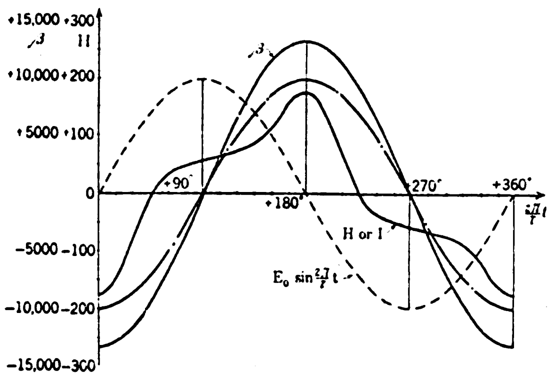

FIG. 13

In said paper (Figs. 4 and 5) the rectilinear characteristic of the metallic reluctivity $\rho = \dfrac{1}{4\pi\kappa}$ when plotted against H is particularly stressed.

With the results of our theory conceded, calling for internal reactive forces R and D, *only that part* of H which is equal $-R$ remains available for magnetization proper. If ρ be therefore related to $-R$, instead of H, we get for the metallic reluctivity

$$\rho = \frac{1}{4\pi\kappa} = \frac{-R}{\beta} = \frac{-R}{\mp S} e^{\phi}$$

use $-S$ when R = positive
use $+S$ when R = negative

and for the apparent reluctivity

$$r = \frac{1}{\mu} = \frac{\rho}{1+\rho}$$

both of which are illustrated in Fig. 14 at two different scales for our sample of hardened Tungsten Steel.

We note particularly that for large values of $R-$ (which differ only slightly from corresponding values of H) ρ is very nearly a straight line whose asymptote runs through the origin of the system at an inclination

$\tan \tau = \dfrac{1}{S}$, which in our case $\dfrac{1}{16000} = 0.0000625.$

It is of the same order as the gradient of right hand end of curve for "Glass Hard Pianoforte Steel, Ewing 1890," given in Fig. 5 of Professor Kennelly's paper. The straight lines (substitutes for curves) in said Fig. 5 do, however, not run through origin, because those curves are plotted against H, which includes the component opposing D.

Even diamagnetism may be explained now, by reversing in above formula for ρ the sign of R. That is permissible from the mathematical standpoint and conceivable from the physical standpoint so long as β in Fig. 4 remains between the limits $+S$ and $-S$. Reversal of sign of R takes place automatically when $\beta > S$, but such a condition cannot be reconciled with our definition of S as a maximum value of β.

Notations and Symbols Used in This Paper

B Induction or flux density
H Magnetizing force; also spatial induction
β Intrinsic induction (*i. e.*, $B - H$)
S Saturation value, that is the limiting value of β
γ Capacity for further induction (*i. e.*, $S - \beta$)
R Reactive component of internal force, opposing magnetization in either direction.
D Dissipative component of the internal force, opposing all changes of induction β.
M Maximum value of $(-D_1 + D_2)$
Subscript$_1$ indicates appertainment to ascending branch of hysteresis loop
Subscript$_2$ indicates appertainment to descending branch of hysteresis loop
Subscript$_h$ indicates highest vaule attained

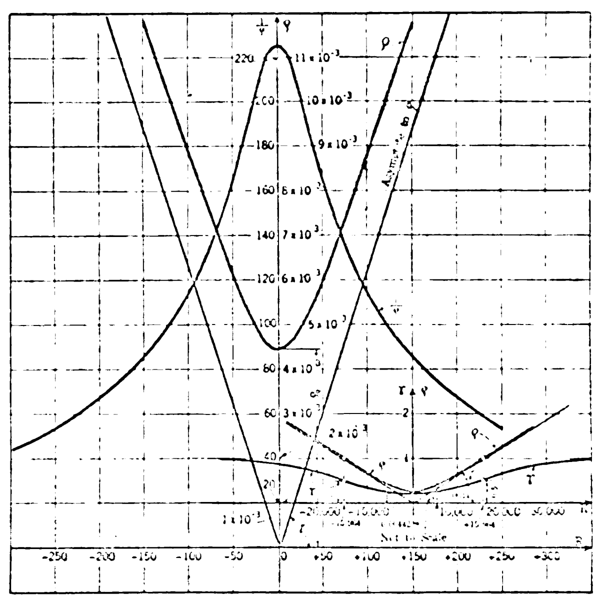

FIG. 14

Subscript$_0$ indicates that a related quantity has zero value
θ = $u + \varphi$, a hyperbolic angle
α = a circular angle
v = a hyperbolic angle

The unit for quantities B, H, β, S, γ, R, D, M in the $C\,G\,S-$ system is $C^{-1/2}\,G^{1/2}\,S^{-1}$ that is the Gauss = Number of lines of force per square centimeter.
L = Energy Loss in ergs ($C^2\,G\,S^{-2}$).
1.356×10^7 ergs = 1 ft-lb.

For illustration of leading symbols see Figs. 1 to 4.

Steady-State Stability in Transmission Systems
Calculation by Means of Equivalent Circuits or Circle Diagrams

BY EDITH CLARKE[1]

Associate, A. I. E. E.

Synopsis.—*The maximum load on a proposed transmission system must be within the steady-state power limit of the system for stability of operation. Two methods of calculating steady state stability are given in detail and illustrated by examples. (1) The given transmission system is replaced by a simple equivalent system, then the steady-state power limit of this equivalent system is determined graphically. (2) By means of a circle diagram the system is tested for stability with the maximum proposed load on the system.*

All formulas from published references necessary for the calculations are included and all calculations are given in full so that similar studies can readily be made by an engineer who has not previously made a study of the subject of stability.

THE object of this paper is to give two methods of determining the stability of operation of a proposed transmission system under steady-state conditions. The calculations will be given in detail so that the engineer who has not previously made a study of the subject will have no difficulty in applying the tests for stability to his system. The first method is by means of an equivalent circuit and the second by means of a circle diagram. Both methods are based on theorems which are exact, but in order to fit the transmission system to the theorems certain assumptions must be made. The results will therefore be approximate to the extent to which the assumptions approximate actual conditions.

Formerly when a transmission system was proposed, it was customary to make the line calculations for voltage regulation and losses for the maximum load conditions, and to select the generators, transformers and synchronous condensers to fit these conditions. There was nothing in such calculations to indicate that the system would be stable, but fortunately the length of line and maximum load have been such that cases of instability have been rare. At the present time when the tendency is for longer lines and greater loads, it is necessary to consider the question of stability both for steady state and transient conditions. Steady-state stability only will be considered in this paper.

In steady-state stability the assumption is made that the load comes on in infinitesimal amounts so that the transient caused by one increment is over before the next increment is added. The criterion of steady-state stability is this: Assuming that the system is operating satisfactorily under the assumed load conditions, will it continue to operate satisfactorily if an increment of synchronous load is added and all excitations remain constant? When load is added there is an increase in current and a drop in voltage before there is any change in excitation. The voltage regulators then increase the excitations and normal voltage is obtained. If the load on the system is *just* the amount which can be transmitted at excitations which correspond to normal voltage, any increase in synchronous load will cause instability because the voltage must drop before the voltage regulators can increase the excitations and at the given excitations no more power can be transmitted. Therefore, when the voltage starts to drop it will continue to drop, for there is no voltage at which the load can be transmitted with those excitations.

When a generator and motor are on the same bus, at no-load, neglecting no-load losses, their induced voltages are in phase. Keeping the excitations on motor and generator constant as the motor is gradually loaded, the phase displacement between the excitation voltages of motor and generator increases with load until the machines fall out of step. The load at which the machines fall out of step is the maximum load and the angle is the maximum power angle. This angle and the power corresponding to it can be calculated. Power corresponding to an angle greater than the maximum power angle can also be calculated although it cannot be delivered.

In the simple transmission system consisting of a synchronous generator supplying power to a synchronous motor over a line having resistance and reactance, but no appreciable capacitance or leakance, the maximum power that can be transmitted over the system, and the angle between the generator and motor excitation voltages corresponding to maximum power, are not difficult to calculate. This simple system will be stable under a proposed load if the phase displacement between the synchronous generator and synchronous motor excitation voltages corresponding to the proposed load is less than the phase displacement which corresponds to maximum power on the shaft of the motor. When a transmission system consisting of generators, lines with distributed constants, and the usual station load can be replaced by the simple transmission system, the maximum power that can be transmitted over the system is easily calculated. In studying steady-state stability by means of equivalent circuits an attempt is made to replace the complicated transmission system by the equivalent simple system.

Abridgment of paper presented at the Midwinter Convention of the A. I. E. E., New York, Feb. 8-11, 1926. Complete copies available upon request.

Equivalent Line

Dr. E. A. Kennelly[2] has shown that a line with distributed constants can be replaced by either an equivalent π or T line in which the constants are lumped. The π line consists of a line with a shunt at each end and the T line of a line with a shunt at the center. The nominal π is formed by placing the total impedance, Z, of the actual line in the line or architrave of the π and one-half the admittance, Y, in each shunt or pillar. The nominal T is formed by placing one-half the total impedance of the actual line in each arm of the T and the total admittance in the shunt or staff. The nominal π and T lines are not exact equivalents of the actual line, but by applying correcting factors to them the equivalent π and T lines are obtained which are exact equivalents of the actual line.

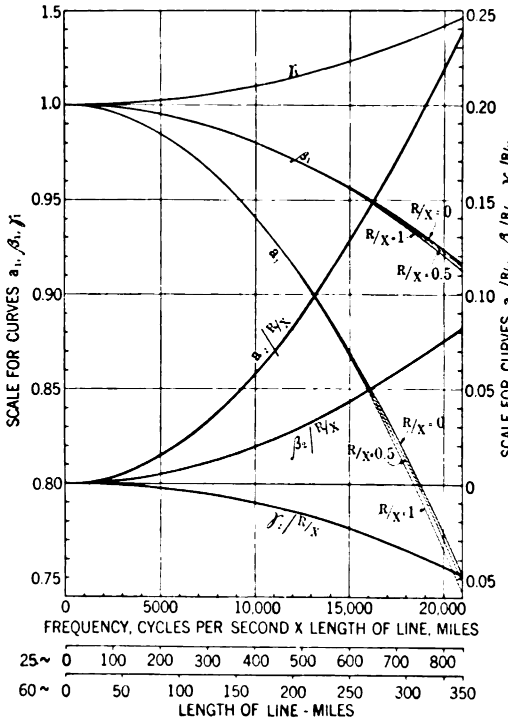

Fig. 1—Complex Hyperbolic Functions

$$\cosh \sqrt{Z\,Y} = 1 + \frac{Z\,Y}{2} + \ldots = a_1 + j\,a_2$$

$$\frac{\sinh \sqrt{Z\,Y}}{\sqrt{Z\,Y}} = 1 + \frac{Z\,Y}{2} + \ldots = \beta_1 + \beta_2$$

$$\frac{\tanh \sqrt{Z\,Y/2}}{\sqrt{Z\,Y/2}} = \gamma_1 + j\,\gamma_2$$

Correcting Factors for Converting the Nominal π or T Line Into the Equivalent π or T. The correcting factors which must be applied to convert the nominal π or T into the equivalent π or T are $\dfrac{\sinh \sqrt{Z\,Y}}{\sqrt{Z\,Y}}$ to be applied to the architrave of the π and the staff of the T and $\dfrac{\tanh (\sqrt{Z\,Y/2})}{\sqrt{Z\,Y/2}}$ to be applied to the pillars of the π and the arms of the T.

2. "Application of Hyperbolic Functions to Electric Engineering Problems."

Fig. 1 gives the real and imaginary parts of these correcting factors. For convenience the real and imaginary parts of cosh $\sqrt{Z\,Y}$ are also given.

Power at a Point Within the Equivalent π. The π-line viewed from either end is an exact equivalent of the line with distributed constants but the current and voltage at any point in the architrave of the π do not correspond to current and voltage on the actual line. Let the π-line in Fig. 2 be the equivalent π of the line $A\,B$ with distributed constants. Although the current at d is the same as the current at B, the current at c has no counterpart in the actual line. The power at d is the same as the power at B, but the power at c is the power at d plus the power lost in shunt Z_4. When the power is known at b and c it can be calculated at a and d.

Synchronous Impedance

It is understood that the synchronous impedance of a synchronous generator or motor is not constant. However, given the characteristics of the machine and the conditions of operation, it is possible to find an *equivalent* synchronous impedance which may be considered constant for the case under consideration. In the work which follows constant synchronous impedance refers to this equivalent synchronous impedance.

For the synchronous condenser it is necessary to find an equivalent excitation as well as an equivalent synchronous impedance. This is discussed at greater length in Appendix E.

Equivalent Generator

If a system consist of a synchronous generator and synchronous motor, both of constant synchronous impedance, connected by a line with a shunt at the generator end, this system can be replaced for all points beyond the shunt by a system unchanged beyond the shunt, but having a new generator whose impedance is the impedance of the generator and shunt in parallel and whose excitation voltage

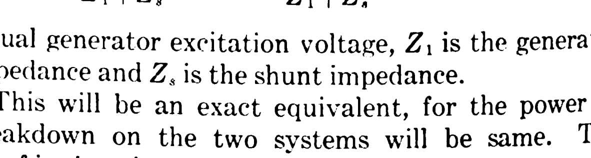

Fig. 2—A. Line $A\,B$ with Distributed constants
B. Equivalent π = Line

$$E_1' = E_1 \frac{Z_1\,Z_s}{Z_1 + Z_s} \div Z_1 = E_1 \frac{Z_s}{Z_1 + Z_s},$$ where E_1 is the actual generator excitation voltage, Z_1 is the generator impedance and Z_s is the shunt impedance.

This will be an exact equivalent, for the power at breakdown on the two systems will be same. The proof is given in Appendix C (b).

Equivalent Motor

If a system consist of a synchronous generator and synchronous motor, both of constant synchronous

impedance, connected by a line with a shunt at the motor end this system can be replaced for all points in front of the shunt by a system unchanged up to the shunt, but having a new motor whose impedance is the impedance of the motor and shunt in parallel and whose excitation voltage $E_2' = E_2 \dfrac{Z_2 Z_s}{Z_2 + Z_s} / Z_2$ $= E_2 \dfrac{Z_s}{Z_2 + Z_s}$, where E_2 is the actual motor excitation voltage, Z_2 is the motor impedance and Z_s is the shunt impedance; but power on the fictitious system corresponding to breakdown power on the actual system occurs when the phase displacement between the generator and equivalent motor excitation voltages is the total impedance angle of the fictitious system plus the angle, $2(\theta_2 - \theta_2')$, where θ_2 is the impedance angle of the actual motor and θ_2' is the impedance angle of the equivalent motor. The proof is given in Appendix C (*b*).

Equivalent System and Voltage Regulators

If a system consists of a synchronous generator and synchronous motor, both of constant synchronous impedance, connected by a line with a shunt at each end, voltage being maintained at the ends of the line, this system can be replaced for all points of the line by a system consisting of the same line without shunts, a generator whose impedance is the impedance of the actual generator and shunt at the generator end in parallel and a motor whose impedance is the impedance of the actual motor and shunt at the motor end in parallel; but power on the fictitious system corresponding to breakdown power on the actual system occurs when the phase displacement between equivalent motor and generator excitation voltages is the total impedance angle of the fictitious system plus $2(\theta_2 - \theta_2')$ where θ_2 is the impedance angle of the actual motor and θ_2' the impedance angle of the equivalent motor. The proof is given in Appendix D.

When $2(\theta_2 - \theta_2') = 0$ deg., the fictitious system becomes an equivalent system, for the power at breakdown on the two systems will be the same. When resistance is neglected in the motor and motor end shunt $2(\theta_2 - \theta_2') = 0$ deg. or 360 deg.

Since no limitation is placed on the shunt impedances in the proofs given in the appendix, in addition to representing the capacitance in the line, they may represent reactors, resistance load or any other dead load.

Equivalent Circuit Method

Graphical Solution. When the actual system has been replaced by the equivalent simple system, the maximum power which can be transmitted may be obtained graphically.

Let Fig. 3A represent the simple equivalent system, where

$Z_5 = r + jx =$ the impedance of the equivalent line.

$Z_1 = r_1 + jx_1 =$ the actual generator impedance.

$Z_1' = r_1' + jx_1 =$ the equivalent generator impedance formed by taking the shunts at the generator end of the line in parallel with the generator impedance.

$Z_2 = r_2 + jx_2 =$ the actual motor impedance.

$Z_2' = r_2' + jx_2' =$ the equivalent motor impedance formed by taking the shunts at the motor end of the line in parallel with the motor impedance.

E_1 = excitation voltage of the actual generator.

E_2 = excitation voltage of the actual motor.

E_1' = excitation voltage of the equivalent generator $= E_1 \dfrac{Z_1'}{Z_1}$

E_2' = excitation voltage of the equivalent motor $= E_2 \dfrac{Z_2'}{Z_2}$

E_A = terminal voltage at the generator end of the line.

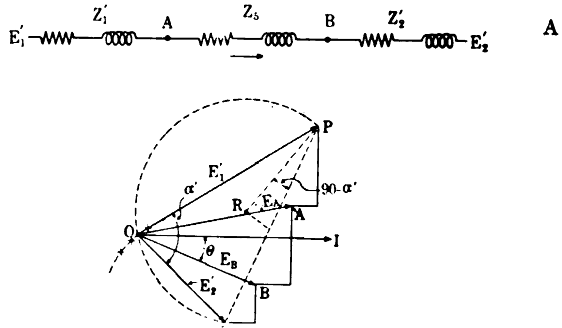

FIG. 3—A. EQUIVALENT TRANSMISSION SYSTEM
B. GRAPHICAL DETERMINATION OF MAXIMUM POWER OVER THE EQUIVALENT TRANSMISSION SYSTEM

E_B = terminal voltage at the receiver end of the line.

$Z_t = (r + jx + r_1' + jx_1' + r_2' + jx_2') = R_t + jX_t$
$= z_t\, e^{j\theta t}$
= total impedance of the equivalent system.

$\theta_t = \tan^{-1} \dfrac{X_t}{R_t}$ = total impedance angle.

$\theta_2 = \tan^{-1} \dfrac{x_2}{r_2}$ = impedance angle of the actual motor.

$\theta_2' = \tan^{-1} \dfrac{x_2'}{r_2'}$ impedance angle of the equivalent motor.

Calculate $\alpha' = \theta_t + 2(\theta_2 - \theta_2')$

Since there are no shunts in the equivalent or fictitious system the same current will flow in all parts of the circuit. Taking current as standard phase, lay off

$QBAP = I(r_2' + jx_2') + I(r + jx) + I(r_1' + jx_1')$

to any convenient scale. Fig. 3B. The value of this scale will be determined when the construction has been completed and the position of point O determined.

There are two conditions which determined the position of point O.

1. $\alpha' = \theta_t + 2(\theta_2 - \theta_2')$

2. The ratio between the magnitudes of E_A and E_B or between E_1' and E_2' is known. For a regulated line E_A and E_B are given, and for a line without voltage regulators E_1' and E_2' can be calculated from the known values E_1 and E_2.

Consider the case of the regulated line: To satisfy the first condition join P and Q and at P drawn PR making an angle, $(90° - \alpha')$ with PQ. With R, the intersection of PR with the perpendicular bisector of PQ, as a center and RP as radius describe arc PQ. If point O lies on this arc, the first condition will be satisfied. To satisfy the second condition, find a series of points whose distances from A and B are in the ratio E_A/E_B and draw a curve through them. O will lie on the intersection of this curve with the arc PQ.

The scale of the vector diagram is determined, for $OB = E_B$. All voltage drops are now given in terms of E_B. E_B is known, therefore all voltage drops are known and the current can be calculated. The power factor angle, θ, can be measured.

Maximum Power at $B = E_B \,.\, I \,.\, \cos\theta$.

The impedances, voltages and currents may be expressed in ohms, volts and amperes respectively or in per cent, as is most convenient.

Algebraic Solution—Resistance Neglected. When resistance is neglected and equal voltages are maintained at the ends of the line a simple formula can be derived for the power delivered.

If

X_1' = the equivalent generator reactance.
X_2' = the equivalent motor reactance.
X = the equivalent line reactance.
V_A = V_B = magnitude of line terminal voltages, E_A and E_B.

$$P_{max} = \frac{V_B^2\sqrt{\left(X_1' + \frac{X}{2}\right)\left(X_2' + \frac{X}{2}\right)}}{\left(\frac{X}{2}\right)^2 + \left(X_1' + \frac{X}{2}\right)\left(X_2' + \frac{X}{2}\right)} \qquad (1)^*$$

When V_B is in volts to neutral, and reactances are in ohms, power will be in watts per phase. If voltages and reactances are in per cent, power will be in per cent (20% = 0.20).

When V_B = 100 per cent and the motor and generator have the same impedance $(X_1' = X_2')$, equation (1) becomes

$$P_{max} = \frac{X_1' + \frac{X}{2}}{\left(\frac{X}{2}\right)^2 + \left(X_1' + \frac{X}{2}\right)^2} \qquad (2)$$

*This equation was first developed by C. A. Nickle.

When $X = O$, which is the case for a motor and generator on the same bus,

$$P_{max} = \frac{1}{X_1'} \qquad (3)$$

When $X_1' = X_2' = O$, which is the case for infinite busses at the ends of the line,

$$P_{max} = \frac{1}{X} \qquad (4)$$

Application of the Fictitious or Equivalent System to Steady State Stability Problems

1. *Effect of Capacitance in the Line.* If resistance is neglected and generator and motor of equal impedances are assumed, equation (2) may be used to calculate maximum power over the line with and without capacitance. Without capacitance, X_1' will be the actual generator impedance. Capacitance in the line

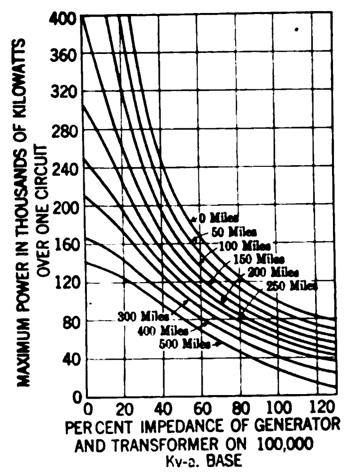

Fig. 5—Maximum Synchronous Load Delivered over 220-Kv., 60 Cycle, Transmission Lines of Various Lengths

When resistance is neglected. Synchronous generators and motors assumed to have equal synchronous impedances. (Transformer impedance included in generator impedance)

will reduce X, since X is multiplied by the correcting factor β which is less than unity, but it will increase X_1', for when the negative reactances of the shunts of the equivalent π-line are combined in parallel with the positive reactances of the machines, the equivalent reactances are greater than the actual machine reactances. The effect of capacitance will be to increase or decrease the maximum power depending upon whether the change in X or in X_1' has the greater influence.

Curves for Estimating Maximum Power

The curves in Fig. 5 were calculated for 60 cycles and various lengths of line, assuming reactance of 0.813 mhos per mile and capacity susceptance of 5.22×10^{-6} mhos per mile, 220 kv. was maintained at each end of the line, resistance was neglected in the line and in the generators and motors which were assumed of equal synchronous impedances. These curves can be used as a first approximation.

2. *Reactor Across the Generator Terminals.* If a reactor is placed across the generator terminals the effect is opposite to the effect produced by the capacity shunt. The reactor reduces the equivalent generator impedance so that more power can be transmitted over the system. It must be remembered that the excitation on the generator is increased by the use of a reactor, but when full field is not being used on the generator, a reactor increases the power that can be transmitted by the same amount that a generator of the same rating would do. Since reactors are cheaper than generators, a reactor of the size that would put full excitation on the generator can be used to advantage to increase the stability of the system.

3. *Power Limits of a Long Line.*

a. Limit of the line alone.
b. Limit of the line and transformers.
c. Limit of the line transformers and generator.
d. Limit of the system with various kinds of load.
 1. Synchronous motors.
 2. Lights and synchronous motors.
 3. Lights, induction motors, synchronous motors and synchronous condensers.
 4. Same as (3) but with a generator supplying local load.

A line with generator and transformers will be selected then the maximum power will be obtained for the specified conditions.

Given:

A three phase, 60 cycle, 250 mile line.

Line constants: r = 0.151 ohms per mile
x = 0.813 ohms per mile
y = 5.22 micro-mhos per mile
Leakance = O.

Step-up transformers: 270,000 kv-a. total
2 per cent resistance
12 per cent reactance
13,200—220,000 volts.

Step-down transformers: 240,000 kv-a. total,
2 per cent resistance
12 per cent reactance
210,000-13,200 volts

Generators: 270,000 kv-a. total
0.9 power factor, 13,200 volts
100 per cent synchronous impedance.

Voltage regulators will maintain 220 kv. and 200 kv. at the generator and receiver ends respectively on the low sides of the transformers (assuming a one-to-one ratio of transformation). The magnetizing current in the transformers will be neglected.

From equation (**7**) Appendix C (*a*).

$$P_{max} = \frac{V_1 V_2}{z}\left(1 - \frac{V_2}{V_1}\cos\theta\right),$$ where V_1 and V_2 are terminal voltages at the generator and receiver ends respectively, Z is total impedance, and θ is total impedance angle.

When V_1 and V_2 are in volts to neutral and Z is in ohms, power will be in watts per phase. If voltages and impedances are in per cent, power will be in per cent (20 per cent = 0.20).

When V_1 and V_2 are bus voltages, Z the total impedance between the buses and θ the total impedance angle, P_{max} will be the maximum power that can be exchanged between the buses.

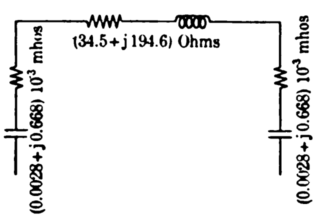

FIG. 6—EQUIVALENT π OF THE TRANSMISSION LINE ALONE

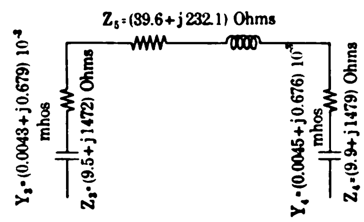

FIG. 9—EQUIVALENT π OF THE LINE AND TRANSFORMERS

When V_1 and V_2 are excitation voltages of synchronous generator and synchronous motor respectively, Z the total impedance between them and θ the total impedance angle, P_{max} will be the synchronizing power between the two machines.

Fig. 6 gives the equivalent π of the line alone. Fig. 9 gives the equivalent π of the line and transformers.

The maximum power which can be transmitted over the line alone and over the line with transformers may be obtained by subtracting the power lost in the receiver shunt from the total power which can be exchanged between the buses.

(a) The limit of the line alone = 187,000 kw.

(b) The limit of the line with transformers = 158,500 kv.

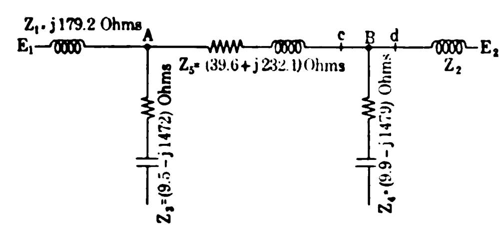

FIG. 11—EQUIVALENT π OF THE LINE AND TRANSFORMERS

With synchronous generator and motor. Impedances are in ohms referred to the high side.

(c) Limit of the line, transformers and generator is obtained by assuming a motor of zero impedance or an infinite bus at the receiver end.

Fig. 11 represents the line with end shunts and a motor and generator each of constant synchronous impedance. The power at *d*, that is the power de-

livered to the load, will be the power at c minus the power lost in Z_4. Fig. 12 gives the equivalent circuit with the impedances in per cent on a 100,000 kv-a. base. 100 per cent voltage = 200 kv. The shunt Z_3 has been combined in parallel with the generator impedance. The shunt Z_3 has not been combined with the motor impedance.

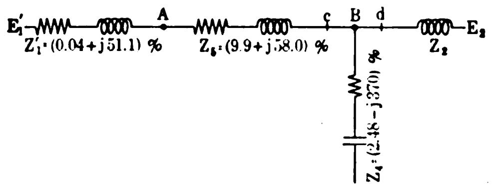

FIG. 12—EQUIVALENT CIRCUIT OF LINE, TRANSFORMERS, GENERATOR AND MOTOR

Impedances are in per cent on a 100,000-kv-a. base. 100 per cent voltage = 200 kv.

The voltages and impedances in per cent from Fig. 12 are

E_A = 110 per cent, E_B = 100 per cent,

$Z_1' = (0.04 + j\,51.1)$ per cent, $Z_2' = O$

$Z_5 = (9.9 + j\,58.0)$ per cent,

$Z_5 + Z_1' + Z_2' = (9.9 + j\,109.1)$ per cent $= Z_t$

α' = maximum power angle $= \theta_t + 2\,(\theta_2 - \theta_2') = \theta_t$

$$= \tan^{-1}\frac{109.1}{9.94} = 84.7 \text{ deg.}$$

Making the graphical construction as described above, Fig. 13 is obtained. From Fig. 13

$$\text{Since } O\,B = 100 \text{ per cent Voltage, } I = \frac{\overline{B\,P}}{\overline{O\,B}} \Big/_{st}$$

$$= \frac{1.845}{1.095} = 1.685 = 168.5 \text{ per cent current.}$$

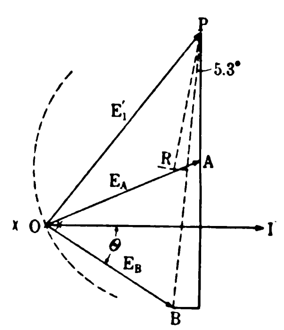

FIG. 13—GRAPHICAL DETERMINATION OF MAXIMUM POWER WITH AN INFINITE BUS AT THE RECEIVER END

Power factor at B = 0.84 lead.

Power at c = 1 × 1.685 × 0.84 = 1.415

= 141.5 per cent on 100,000 kv-a. base

= 141,500 kw.

Power lost in shunt Z_4 = 180 kw.

Limit of the line, transformers and generators = 141,300 kw.

d. Limit of the system with various kinds of load.

1. Synchronous motor load of total capacity 170,000 kv-a., 85 per cent synchronous impedance.

Z_2 = motor impedance on 100,000 kv-a. base = 50 per cent

$$Z_2' = \frac{Z_2\,Z_4}{Z_2 + Z_4} = \text{impedance of equivalent motor}$$

$= (0.07 + j\,57.8)$ per cent

Fig. 14 gives the equivalent circuit.

Z_t = total impedance = $(10.0 + j\,166.9)$ per cent.

θ_t = total impedance angle = 86.6 deg.

θ_2 = impedance angle of actual motor = 90 deg.

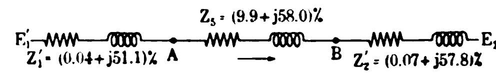

FIG. 14—EQUIVALENT CIRCUIT FOR SYNCHRONOUS MOTOR LOAD

θ_2' = impedance angle of equivalent motor = 89.9 deg.

$2\,(\theta_2 - \theta_2')$ = 0.2 deg.

$\alpha' = \theta_t + 2\,(\theta_2 - \theta_2') = 86.7$ deg.

Using the equivalent circuit given in Fig 14 and. making the graphical construction as described above, Fig. 15 is obtained.

Since $O\,B$ = 100 per cent voltage, I = 112.5 per cent current and

Power factor at B = 0.943 lead.

Power at c = 1 × 1.125 × 0.943 = 1.06

= 106,000 kw.

Power lost in shunt Z_4 = 180 kw.

Maximum power that can be delivered to the load = 106,000 kw.

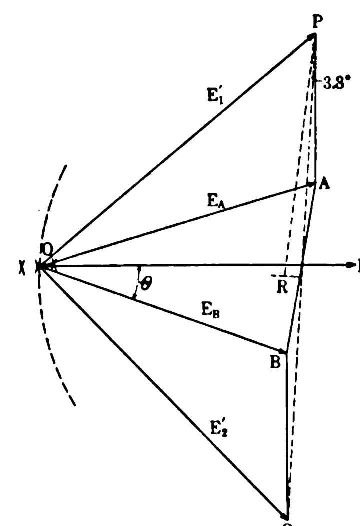

FIG. 15—GRAPHICAL DETERMINATION OF MAXIMUM POWER FOR A SYNCHRONOUS MOTOR LOAD

2. Resistance load of 30,000 kw., synchronous motors of total capacity 170,000 kv-a. with 85 per cent synchronous impedance.

R = resistance of the resistance load shunt.

= 1333 ohms.

= 333.3 per cent on 100,000 kv-a.; base, 200 kv.

Z_4' = impedance of Z_4 and R in parallel = $(184 - j\,165)$ per cent

Z_2 = impedance of actual motor = 50 per cent

$Z_2' = \dfrac{Z_2 Z_4'}{Z_2 + Z_4'}$ = impedance of equivalent motor $= (9.8 + j\,56.1)$ per cent

Z_t = total impedance of equivalent circuit = $(19.74 + j\,165.2)$ per cent

θ_t = 83.2 deg. = total impedance angle.

$\alpha' = \theta_t + 2(\theta_2 - \theta_2') = 83.2\text{deg.} + 2\,(90 - 80.1\text{deg.}) = 103.0$ deg.

The graphical construction is given in Fig. 16.

Since $O\,B$ = 100 per cent

I = 138.5 per cent and power factor at B = 0.90 lead

Power at $c = 1 \times 1.385 \times 0.90 = 1.248$ = 124,800 kw.

Power lost in the line shunt Z_4 = 180 kw.

Maximum power that can be delivered to the load = 124,600 kw.

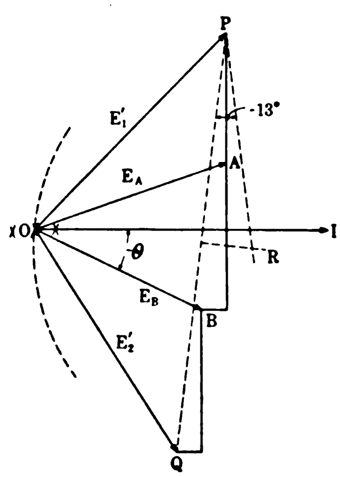

FIG. 16—GRAPHICAL DETERMINATION OF MAXIMUM POWER FOR A LOAD PARTLY RESISTANCE AND PARTLY SYNCHRONOUS

3. Lights, induction motors, synchronous motors and synchronous condensers.

4. Same as (3) but with generator supplying local load.

As voltage drops on an induction motor load, the power required by the load remains practically constant and the power factor becomes less lagging. A lightly loaded synchronous motor has the same characteristics. The induction motor load therefore, may be replaced by an approximately equivalent synchronous motor.

A method of treating the synchronous condenser in the equivalent circuit is given in Appendix E.

Examples of type (3) can be solved by the equivalent circuit method but the solution with the circle diagram is more satisfactory than the solution by the equivalent circuit method available at present. An example of type (4) is solved by the circle diagram method. See example (3) following. It is hoped that systems more complicated than the one considered here as well as examples of types (3) and (4), will eventually be completely represented by equivalent circuits.

CIRCLE DIAGRAM METHOD

The test for stability by this method is to assume a slight increase in load and to determine if by a drop in receiver voltage this new load can be carried with the excitations corresponding to the original load.

When a system is operating at normal voltage ana a load is added there is an increase in current at the receiver end and a drop in voltage. The power given to the additional load comes from the change in phase displacement between the sending and receiving end equipment. Due to the drop in voltage at the load, the original load does not require the same power it required at normal voltage if it is the average station load. The kw. and kv-a. taken by the original load changes with voltage. If voltage slightly less than normal is assumed at the receiver end and the kw. and kv-a. corresponding to the original load at this voltage plus a small load increment can be transmitted over the line with the given generator excitation, the system is stable, for the small increment is the contribution to the additional load made by the change in phase displacement of the system. For the limit of stability this increment approaches zero.

The method of obtaining the general circuit constants of a transmission system, and the construction of the power circle diagram from these constants has been described by Mr. R. D. Evans and Mr. H. K. Sels in a paper[4] before the Institute.

GENERAL CIRCUIT CONSTANTS

The same line, transformers and generator used to illustrate the equivalent circuit method will be used for the circle diagram.

The constants of the line alone are:

$$A = D = \cosh \sqrt{Y\,Z} = a_1 + j\,a_2 = 0.8700 + j\,0.0236$$

$$B = Z\frac{\sinh \sqrt{Z\,Y}}{\sqrt{Z\,Y}} = Z\,(\beta_1 + j\,\beta_2) = 34.52 + j\,194.6$$

$$C = Y\frac{\sinh \sqrt{Z\,Y}}{\sqrt{Z\,Y}} = Y\,(\beta_1 + j\,\beta_2)$$

$$= (-\,0.0104 + j\,1.248)\,10^{-3}$$

(a_1, a_2, β_1 and β_2 obtained from Fig. 1.)

The circuit constants of the line and the step-up and step-down transformers, neglecting magnetizing current, are calculated from *Item* (g) of the Evans and Sels paper.[5] To include magnetizing current *Item* (j) should be used instead of (g).

$A_0 = A + C\,Z_s = 0.8431 + j\,0.0279$

$B_0 = B + A\,(Z_s + Z_r) + C\,Z_s\,Z_r = 39.6 + j\,232.1$

$C_0 = C = (-\,0.0104 + j\,1.248)\,10^{-3}$

$D_0 = A + C\,Z_s = 0.8424 + j\,0.0280$

Z_s and Z_r are the transformer impedances at the sending and receiving ends respectively.

4. Power Limitation of Transmission Systems, TRANSACTIONS of the A. I. E. E., Vol. 43, 1924, page 33.

It is of interest to note that these constants can be obtained from the equivalent π including the line and transformer or the equivalent π can be obtained from these constants. See Appendix F.

The circuit constants including the generator as well as the line and transformers are

$$A_{00} = A_0 + Z_1 C_0 = 0.6193 + j\,0.0260$$
$$B_{00} = Z_1 D_0 + B_0 = 34.59 + j\,383.1$$

Where A_0, B_0, C_0 and D_0 refer to the circuit constants of the line and transformers and Z_1 is the generator impedance.

Construction of the Circle Diagram

$$(P_R + l\,E_R^2)^2 + (Q_R + m\,E_R^2)^2 = n^2\,E_R^2\,E_s^2 *$$

is the equation of the Receiver Power Circle Diagram in volt-amperes. If the question is expressed in kilovolt amperes and divided by E_R^4 it becomes

$$\left(\frac{P_R}{E_R^2} + l\,10^3\right)^2 + \left(\frac{Q_R}{E_r^2} + m\,10^3\right)^2 = \left(n\,10^3\,\frac{E_s}{E_r}\right)^2$$

This is a circle for receiver power in terms of the receiver voltage and the ratio between the sending and receiving voltages. The center of the circle is at the point $-\,l\,10^3,\ -\,m\,10^3$.

If

$$A_0 = a_1 + j\,a_2$$

and

$$B_0 = R_0 + j\,X_0$$

$$l\,\dagger = \frac{a_1 R_0 + a_2 X_0}{R_0^2 + X_0^2}$$

$$m = \frac{a_1 X_0 - a_2 R_0}{R_0^2 + X_0^2}$$

$$n = \frac{1}{\sqrt{R_0^2 + X_0^2}}$$

Two circle diagrams will be drawn; one for the line and transformers and the other for the line, transformers and generator. Since they are both for power at the receiver end in terms or receiver end voltage, they will be drawn on the same chart. The ratio of the voltage on the low side of the transformer at the generator end to the voltage on the low side at the receiver end for normal operation has been assumed 220/200 = 1.1. One circle with $E_s/E_r = 1.1$ will be drawn in the diagram for the line and transformers. A series of circles with the ratio of the excitation voltage of the generator to the receiver voltage having various values will be drawn for the line, transformers and generator.

The problems already solved by means of the equivalent circuit will now be solved by the circle diagram.

b. The power limit of the line and transformers at the specified voltages is obtained from the dotted circle at the point where the tangent to the circle is vertical. At this point $kw_r/kv_r^2 = 3.95$, and $kw_r = 3.95 \times (200)^2 = 158{,}000$ kw.

c. The power limit of the generator, line and transformers is obtained from the dotted curve at the point where the tangent to the solid circle is vertical. At this point $kw_r/kv_r^2 = 3.53$, and $kw_r = 3.54 \times (200)^2 = 141{,}200$ kw.

The limit of the system with various kinds of load can not be determined directly by means of the circle diagram. A certain load must be assumed and then the system tested for stability with this load. If the system is stable, a larger load should be assumed, but if unstable, a test should be made with a smaller load. If this process is continued until a load is obtained for which the system is stable, but for which there is no margin, this will be the maximum power of the system.

To Test for Stability on the Circle Diagrams

Calculate kw_r/kv_r^2 for the given load at normal voltage and find the corresponding point on the dotted circle. The ratio of generator excitation voltage to receiver voltage is read from the solid circle cutting the dotted circle at this point, and the generator excitation voltage calculated. Assume a receiver voltage slightly less than normal and calculate the active and reactive power of the load corresponding to this voltage, assuming constants excitations. Divide the active and reactive power in kilovolt amperes by the square of the assumed receiver voltage in kilovolts and locate the point on the diagram. Read E_1/E_r at this point and calculate E_1, the generator excitation voltage. If this value of E_1 is equal to or less than the excitation voltage calculated at normal voltage the system is stable. It is sometimes more satisfactory to select a receiver voltage slightly above normal as well as one below normal, then when the corresponding calculated generator excitation voltages are both higher than the excitation voltage corresponding to normal receiver voltage, the assumed load is the power limit.

1. Given: 170,000 kv-a. synchronous motor, 85 per cent synchronous impedance.

It has been shown by the equivalent circuit method that 106,000 kw. is the maximum power that can be delivered to this motor. Testing by means of the circle diagram, Fig. 17, for a load of 106,000 kw., point A, located on the dotted circle for $kw_r/kv_r^2 = 2.65$, gives the generator excitation voltage from the solid circle passing through A as 242 kv. at normal receiver voltage. Point A' corresponds to 98 per cent receiver voltage and A'' to 102 per cent receiver voltage. The corresponding generator excitation voltage in each case is just about 242 kv. which indicates that 106,000 kw. is very near the limit of stability.

2. Given: Resistance load of 30,000 kw., and the synchronous motor of example 1.

The power delivered to a resistance load varies as the square of the voltage. The power delivered to a shaft load is practically independent of voltage. Points

*Equation (28) A. I. E. E. Transactions, Vol. 43, page 36.

†Circle Diagrams for Transmission Systems, R. D. Evans and H. K. Sels, *Electric Journal*, December 1921.

B, B' and B'' on the circle diagram give the generator excitation voltages corresponding to receiver voltages of 100 per cent, 98 per cent and 102 per cent respectively for a load of 120,000 kw., and points C, C' and C'' the corresponding values for a load of 130,000 kw. The system is stable at 120,000 kw. but unstable at 130,000 kw.

3. Given: Total load of 180,000 kw. of which one-third is resistance load, one-third induction motor load and one-third synchronous motor load. The induction motors have an average power factor of 0.7 lag at normal voltage. The synchronous motors have 100 per cent synchronous impedance, are 75 per cent loaded and are operated at unity power factor. A 100,000 kv-a. synchronous condenser is placed at the load. The generators at the receiver end of the line, having total capacity of 100,000 kv-a. and synchronous impedance of 100 per cent, supply 45,000 kw. to the load and part of the reactive kv-a. needed for voltage regulation. Is the system stable?

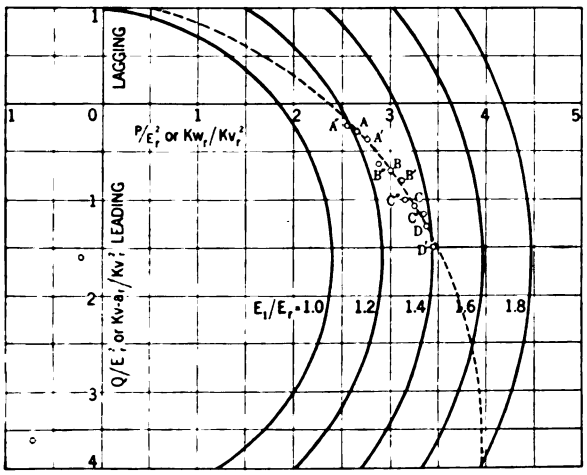

FIG. 17—CIRCLE DIAGRAM FOR THE TRANSMISSION SYSTEM

100 Per Cent Receiver Voltage

E_r = 200 kv. = 100 per cent receiver voltage.

P_r = 135,000 kw. = total power over the line.

$\dfrac{P_r}{E_r^2} = \dfrac{\text{kw}_r}{\text{kv}_r^2} = 3.375$, determines location of point D on dotted circle, Fig. 17.

$\dfrac{Q_r}{E_r^2}$ = 1.28 read at point D, Fig. 17.

Q_r = 51,200 kv-a. = total reactive power over the line.

E_1/E_r = 1.385, obtained from solid circle passing through D.

E_1 = 277 kv. = excitation voltage of generator at sending end.

98% Receiver Voltage.

E_r = 196 kv. = 98 per cent voltage

P_r = 132,600 kw.
Q_r = 57,270 kv-a.
active and reactive power of the original load at 98 per cent receiver voltage and constant excitations.

$\dfrac{P_r + Q_r}{E_r^2} = 3.45 + j\,1.49$, determines location of point D'

E_1/E_r = 1.41, obtained from solid circle passing through D'.

E_1 = 276 kv., excitation voltage of generator at the sending end.

Since E_1, the calculated generator excitation voltage, at 98 per cent receiver voltage is less than E_1 at 100 per cent receiver voltage for the same receiver load, the system is stable. These calculations do not indicate the load which can be added with stability maintained. They merely indicate that the system is stable under the assumed load conditions.

In the examples which have been considered a single generating station supplies power over one circuit to a single receiving station. In more complicated systems where it may be necessary to cut and try, the circle diagram can be used to advantage for the various parts of the system.

ACKNOWLEDGMENT

The idea of combining the shunts at the ends of the line with the synchronous apparatus is due to Mr. C. A. Nickle who proved that "neglecting resistance, a line with synchronous apparatus and reactance or capacitance shunts may be replaced by a line and equivalent synchronous apparatus with no shunts."

The writer wishes gratefully to acknowledge her indebtedness to Messrs. H. H. Dewey and R. E. Doherty for their encouragement and suggestions which have broadened the scope of this study, and to Mr. Nickle for his suggestions in the development of certain phases of the subject.

PURER IRON PRODUCED ELECTRICALLY

Pig iron is now the basic form from which all types of iron and steel are made but it may become obsolete and the direct manufacture of malleable iron and steel from ore may follow the invention of a special electric furnace of commercial size that has been built in the great Hagfors, Stockholm, Sweden, ironworks where iron ore and coal mixed and fused have been made to produce pure iron containing only two per cent of carbon, and steel that can be worked in the usual manner.

The new process is continuous and fusion ceases only temporarily when the furnace is tapped, while the absence of gases and slag produces a superior product.

The United States leads the world in the number of electric steel furnaces in use, and with the discovery of a process of making iron and steel directly from ore would give a tremendous impetus to the use of the electrical smelting furnace.

Studies of Transmission Stability

BY R. D. EVANS* and C. F. WAGNER*
Associate, A. I. E. E. Associate, A. I. E. E.

Synopsis.—*Stability may be defined as the capacity of a power system to remain in equilibrium under steady load conditions, and its ability to regain a state of equilibrium after a disturbance has taken place. The lack of stability first manifested itself in the cases of overloaded machines and high impedance tie lines. The transmission of large blocks of power over long distances has presented the problem in a new form. Attention was directed to this problem in a group of papers before the Institute at the Midwinter Convention of 1924.*

These papers gave a general discussion of the stability problem and pointed out the necessity of considering the limitations imposed not only by the line alone but by the transformers, rotating machines and load. Extensive and pertinent discussions followed which emphasized the importance of the limitations imposed on power transmission by stability conditions.

The papers and discussions at the 1924 Midwinter Convention established a method for the determination of power limits under steady load conditions assuming fixed excitation. The limit so determined is due to the inherent characteristics of machines and does not take into account the possibility of changes in excitation due to the action of voltage regulators. The possibility of exceeding the "inherent stability limits" by the operation of the voltage regulators and exciters was pointed out. This condition of "artificial stability" was not at that time believed to be attainable. It was recognized that under the actual operating conditions on a transmission system instability would occur because of short circuits or other disturbances at a point considerably below the maximum static limit.

Subsequently extensive studies of stability conditions were made to determine the feasibility and economics of a number of large transmission projects. These studies emphasized the necessity of determining the maximum permissible load under the most severe operating conditions which obviously arise at the time of system disturbances, such as switching operations or flashovers with the attendant switching.

Transmission stability has been the subject of a number of articles in the technical press and of papers before the Institute, the principal ones of which are listed in the bibliography. C. L. Fortescue's paper before the Seattle Convention in September 1925 serves as an introduction to the present paper, presenting in a qualitative manner results of recent investigations whereas this paper presents methods for the quantitative determination of system oscillations.

During the early part of 1926 extensive stability tests including switching operations and single phase faults to ground were conducted on the system of the Pacific Gas and Electric Company. These tests will be described in a companion paper by Roy Wilkins.†

The present paper first deals with the principal elements entering into the stability problem, such as the action of generators and exciters during disturbances, effect of dissymmetry produced by single-phase short circuits, simplification of the load end network and methods for combining these various factors in the determination of the electromechanical oscillations of the system following major disturbances. Results of calculations by these methods are compared with the results of tests on the system of the Pacific Gas and Electric Company. The paper concludes with a discussion of various methods of improving stability.

Introduction

FUTURE power developments in this country and in Canada will involve the transmission of larger blocks of power over greater distances than hitherto have been realized in actual practise. Attention is being directed to the possibilities of hydroelectric developments located remote from load centers. In order to compete on an economical basis with high efficiency steam plants located near load centers, it is necessary to transmit large amounts of power per circuit. However, electrical considerations show that the power limits per line closely approach the limits determined by economical considerations. For these reasons the stability of transmission systems is particularly important.

The present investigation of the stability problem has for its object the determination of power limits for a transmission system under the various conditions that arise in actual operation. The results which may be expected of such an investigation include (1) the determination of the proper basis of design of machines and control apparatus for future power developments involving long transmission lines, (2) the development of methods of analysis and testing equipment to determine the performance of existing systems, (3) the improvement of operating methods with a view of reducing the effects of disturbances. This should follow naturally as a result of the better understanding of what takes place during and following a disturbance.

Stability may be defined as the capacity of a power system to remain in equilibrium under steady load conditions and its ability to regain a state of equilibrium after a disturbance has taken place. The first part of this definition is referred to as "static stability" and the second part as "transient stability." It should be noted that after a disturbance the system will not necessarily seek the original state of equilibrium.

The maintenance of stability on a transmission system is obviously of the utmost importance since a line deficient in stability is inoperative. Normal loads on a system must, of course, lie well below the static limit. The importance of transient limits depends largely upon the importance attached to the interruption in power supply over the transmission line. If switching out of a section of line for inspection or repair at times of heavy load would always lead to loss of synchronism, the operating conditions would be intolerable. If the increases in load, which normally take place on a sys-

†"Practical Aspects of System Stability" JOURNAL of A. I. E. E. Feb. 1926.

Abridgment of paper presented at the Midwinter Convention of the A. I. E. E., New York, Feb. 8-11, 1926. Complete copies available upon request.

tem, would result in loss of synchronism, the operating conditions would also be intolerable. If any kind of a fault on a transmission system would always lead to loss of synchronism, the operating conditions would be unsatisfactory. It is recognized that stability cannot be maintained under all abnormal conditions, but the layout should be such as to prevent loss of stability under the more frequently occurring conditions, such as the addition of a reasonable block of load, normal switching operations, and the majority of single-phase, line-to-ground faults. The decision as to the standard of service is important, and, in our opinion, nothing less than that suggested above will be tolerable for the super power transmission systems which have been contemplated.

Reference should be made to the paper by C. L. Fortescue, presented at the Seattle Convention in 1925, which gives a general discussion of static stability and presents a picture of the phenomena taking place during transients. Mr. Fortescue's paper serves as an introduction to the present paper, the former presenting in a qualitative manner results of recent investigations whereas the latter presents methods for the quantitative determination of system oscillations.

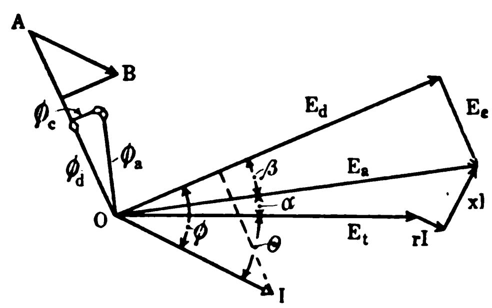

FIG. 1—GENERATOR VECTOR DIAGRAM

METHOD OF CALCULATION OF SYSTEM DISTURBANCES

System disturbances set up oscillations which are essentially the same phenomena regardless of the method of initiation. Consequently, the same general methods of calculation may be applied to of all them. The performance of a system during and following a disturbance will involve the following problems; generator and exciter characteristics, simplification of the load-end network, inertia effect of rotating machines, governor characteristics, dissymmetry due to single-phase short circuits, and methods of combination of electrical and mechanical oscillations into one final result.

GENERATOR CHARACTERISTICS

The effect of generator characteristics during transients can be analyzed conveniently by the Blondel two-reaction method in which the flux is resolved into two components, a direct component in phase with the field poles and linking the field windings and a cross component in quadrature with the field poles. Referring to Fig. 1, I is the armature current, E_t terminal voltage and E_a internal voltage. The latter voltage is resolved into two components, E_d and E_c, which are produced by rotation of the direct component and cross component of flux respectively. During transients, these components, which have associated with them different windings, have different decrements. In salient pole machines test results indicate that the cross component of flux can be assumed to vary instantly to its new value and the variation in direct component of flux can be calculated at any instant by the following formula

$$\frac{d\,E_d}{d\,t} = \frac{10^8}{n\,N\,C_1}\,(e_x - i\,r).$$

where

e_x = exciter voltage at any instant.
$i\,r$ = voltage drop in the field at any instant.
n = turns per pole of field winding.
N = number of poles.
C_1 = flux per pole per generator terminal volt.

The construction of large turbo generators is such as to produce a damping action which prevents rapid change in cross component of flux. In this case, it is sufficiently accurate to assume that the total internal voltage E_a is fixed in phase position relative to the field structure during transients, and that the total component varies in proportion to the direct component.

EXCITATION SYSTEMS

Excitation systems serve to supply the m. m. f. required in synchronous machines to produce the direct component of voltage of such value as to maintain any desired terminal voltage. With hand-operated systems, the excitation remains constant during the transient unless changed by the operator, but with automatic regulators changes in excitation normally take place. Automatic voltage regulators are of two principal types, the vibrating or Tirrill type and the rheostatic type.

The vibrating regulator functions by cutting a block of resistance "in" or "out" of the exciter field circuit at such a rate as to maintain the proper mean value of exciter voltage to supply the required field current for the main machine. The rate of change of exciter voltage for the transient conditions as the contacts open and close can be calculated by the following formula:

$$\frac{d\,e}{d\,t} = \frac{k}{N\;n}\,(e - i\,r)$$

where

N = number of poles.
n = number of turns per pole.
ϕ = flux per pole.
e = $k\,\phi$.
k = voltage produced by rotation of unit flux.

The quantity in parenthesis represents the difference between the terminal voltage and the $i\,r$ drop in the field winding of the exciter, and represents the voltage which must be supplied by the inductive drop in the field winding. This equation expresses the relation

between the rate of change in terminal voltage of the exciter with time as a function of e and i, and enables one by a step-by-step method to determine the exciter voltage as a function of time.

With the rheostatic type of regulator, the exciter voltage remains constant, but the resistance in the main field of the alternator is automatically varied by means of a motor-operated face plate rheostat controlled by the regulator. It may be noted that with this type of regulator the operation occurs in the field circuit of the main machine, whereas with the vibrating type, the operation occurs in the field circuit of the exciter. With the vibrating regulator there is a time lag in the building up of the voltage across the machine terminals due to the time constants of the exciter field, whereas with the rheostatic regulator, a certain amount of time is required for the movement of the motor-operated rheostat.

The Load End Network

A transmission line will usually deliver power to a load end system of considerable extent and having other sources of power. Frequently this "load end network" will have connected to it much greater capacity than the output of the transmission line. The load end network constitutes a problem in stability studies, because rigid analytical methods are frequently impractical on account of the complexity of the network, and because it is difficult to find a network that is equivalent to the actual network, at the same time being sufficiently simple to be handled analytically.

The load end network includes synchronous generators and condensers in addition to the load the principal components of which are synchronous motor, synchronous converter, induction motor and lighting load. E. J. Amberg has given the following segregation of load on a particular system, which segregation appears to be quite typical:

TABLE III

Typical Segregation of Peak Load

Type	Percentage
Induction motor..............	60
Synchronous motor............	10
Synchronous converter.........	10
Lighting.....................	—20

The various types of load have different characteristics. With synchronous and induction motors, the true power demand may be assumed to remain constant with variation in voltage, whereas the lighting and synchronous converter load will vary as the square of the voltage. The reactive power varies greatly with the type of load and in the curves of Fig. 7 are shown the variations of reactive power with variation in terminal voltage.

It is impractical to consider a multitude of individual loads, and it becomes necessary, therefore, to use some such composite load characteristic as shown in Fig. 8. An approximation of the load characteristics that is very convenient is the assumption of a constant impedance shunt load. The variations in load voltage usually are not great because it is maintained by the local generators and synchronous condensers. It is this fact which permits the relatively crude approximation of constant impedance load to give satisfactory results for the majority of cases.

The load characteristic is also affected by changes in system frequency. Quite definite information on this point is available from actual operating experience. J. P. Jollyman* has stated that a reduction in frequency from 60 to 59 cycles will reduce the real power demand by 3.5 per cent.

The method to be employed for analyzing load end networks from the standpoint of stability is dependent chiefly upon the number of synchronous machines. In case the load end network involves one synchronous machine and induction motor and lighting load the network may be replaced by a single synchronous machine with a shunt admittance branch to represent the non-synchronous load. In case there are two or more synchronous machines which would carry proportional loads at times of disturbances, they may be handled in a similar manner. In many cases, the assumption that the voltages of all load end synchronous machines are in phase represents a crude approximation. A quite accurate assumption for such a case is to assume that a constant angular relation between the various synchronous machines is maintained. By this method the synchronous machines are compelled to operate as a unit instead of permitting them to make small movements with respect to each other. On very large receiving systems, disturbances on the transmission system are likely to have relatively little effect on individual machines and it becomes permissible to represent an extensive transmission network with many sources of voltage by a single equivalent network with a single machine and a single shunt admittance to represent non-synchronous load. For very large receiving networks the inertia may be considered infi-

*Stored Mechanical Energy in Transmission Systems, A. I. E. E. Journal, Sept. 1925.

nite or if desired corrections may be introduced in the inertia of the supply end generator.

Mechanical System Data. The stored mechanical energy in the synchronous rotating machinery is important in determining the period of system oscillations and the rate of change of angular positions of rotors, and hence internal voltage in response to changes in input or output. Because of their inertia, the rotors cannot change phase position immediately. During the first instant of a disturbance the redistribution of power can be calculated with the internal voltages in the same position as at the instant immediately preceding a disturbance. Before the beginning of the transient the input and output are equal, the rotor being in equilibrium, but with the redistribution of power the equilibrium is disturbed and the rotors accelerate or decelerate, the rate being determined by the following equation:

$$a = \frac{180\,f}{E}\,\Delta P \qquad (6)$$

where

α = acceleration in electrical degrees per sec. per sec.

f = system frequency.

E = stored mechanical energy at synchronous speed in kilowatt seconds.

ΔP = difference between input and output in kw.

By assuming sufficiently small time intervals and assuming the acceleration constant during the interval, or by assuming larger intervals and correcting for average acceleration, the rotor movements can be traced by a step-by-step method of calculation throughout the period of disturbance.

The stored energy is dependent upon the total mass, the distribution of this mass, and speed. The following table indicates the stored energy in kilowatt-seconds per kilowatt output for a large number of different units of each type of machine.

TABLE IV

STORED ENERGY OF MACHINES

1. Water Wheel Generators. Average of units ranging from 1500 to 35,000 kw. = 2.40 kw.-sec. per kw. From an examination of a small amount of data the flywheel effects of the waterwheels appear to be in the neighborhood of 10 per cent to 20 per cent of the generator flywheel effects.

2. Steam Turbine Generator Units. Average of units ranging from 1500 to 35,000 kw. Generators = 5.32, turbines = 5.65. Total = 10.97 kw.-sec. per kw.

3. Rotary Converters (Railway & Edison). Average of units ranging from 750 to 3250 kw. = 2.10 kw.-sec. per kw.

4. Synchronous Condensers. Average of units ranging from 1000 to 40,000 kv-a. = 1.48 kw.-sec. per kv-a.

The synchronous machinery, and to a lesser extent, the eddies in synchronous machinery, tend to cushion any sudden changes in phase position and voltage. This induction generator effect differs from the synchronous effect in that it is responsive to speed changes rather than angular space changes. However, the effect is small and may be neglected.

Governor Characteristics

The time constants of governors are also important in their effect upon system stability during certain types of disturbances. The acceleration or deceleration of the rotor determining the phase position of the internal voltage depends upon the difference between generator input and output, the input being regulated by the governor. In present day practise, the governor is a device which functions on speed. This point is important as large angular displacements might take place before the governing device begins to function.

In general, however, since governors react only after the speed change and since these changes are extremely small during switching operations, the variations in gate opening can be neglected for these conditions. The action of the governor during single-phase short circuits will depend upon the change in output and the resulting speed change occasioned thereby. For relatively small changes of the order of 25 per cent of rated load, consideration of the "dead time" and the relatively slow traversing rate of about six seconds would justify neglecting any change in gate position due to governor action. In general, one must look into the individual case and determine whether or not the effect of governors can be neglected. If their effect must be taken into account, it will be found convenient in the analysis to plot the variation in speed of machines and in gate opening as functions of time. These curves enable one to determine the interaction between rotor velocity and gate opening throughout the transient condition.

Single-Phase Short Circuits

The calculation of single-phase, short-circuit currents on a transmission network is complicated, because the currents and voltages in the different phases are unsymmetrical. Each phase is inductively coupled with the other phases in transmission lines, transformers and rotating machines. In addition, rotating machines, including synchronous generators, motors and condensers, and also induction motors, provide a distinct phase-balancing action, tending to restore symmetry in voltage and current. Because of the fact that no suitable method had previously been published, the authors found it necessary to develop a method for the solution of the single-phase, short-circuit problem. This method is essentially a combination of two well-known methods of network solutions; namely, phase sequence components, and general circuit constants. In the phase sequence method developed by C. L. Fortescue,* the voltages and currents of a three-phase grounded system are resolved into three components, namely, the positive sequence, the negative sequence, and the zero sequence. This results in an important simplification for the case we are considering of balanced polyphase systems, as the different sequences do not react one upon another. For normal balanced loads, only positive sequence voltages and currents are

*Trans. A. I. E. E., Vol. XXXVII, p. 1027.

present. In case of a line-to-line fault, only the positive and negative sequence components are present; while in the case of a fault to ground, all three components are present. Synchronous machines generate only positive sequence e. m. fs. and the negative and zero sequence voltages appearing at machine terminals are due to the voltage drops produced by negative and zero sequence currents, respectively. Since polyphase synchronous machines generate only positive sequence voltages, it follows that machine decrements involve only positive sequence voltages and currents, and the constants of the machines and the network to which they are connected. In other words, it is possible to compute the decrements for single-phase short circuit by the methods applicable to three-phase short-circuits if the positive sequence voltages and currents of the various machines are considered.

The most convenient methods for handling transmission networks employ the general circuit constants developed by Evans and Sels. In this connection, it may be pointed out that the recent revision of the book "Electrical Characteristics of Transmission Lines" by William Nesbit gives a very complete series of tables of the general circuit constants for transmission lines covering the commercial ranges of conductors and spacings for lines from 50 to 300 miles in length. The method of general circuit constants was originally developed for the solution of balanced three-phase systems where only positive sequence components of currents and voltages are present. The method, however, can readily be extended for negative and zero sequence components.

It can be shown that the effect upon the positive sequence voltage and current of a wire-to-wire or wire-to-ground fault can be accurately represented by replacing the fault by a symmetrical impedance to ground. For a line-to-ground fault this impedance per phase will be equivalent to the sum of the negative and zero sequence impedances as measured at the point of fault, and for the wire-to-wire fault the equivalent impedance is equal to the negative sequence impedance as measured at the point of fault.

Combination of Factors

The various individual factors entering into the problem of stability have been discussed in the previous section. These factors are combined in a step-by-step method to obtain the magnitude of system oscillations. Reference should be made to the complete paper for a more detailed description of the method. The results of the calculations are plotted in the form of angle time, voltage time, and power time diagrams from which a very good estimate of the stability of operation can be obtained.

Application of Methods to Various Types of System Disturbances

The methods of calculating system oscillations described in the preceding Section will now be discussed with respect to their application to the various types of system disturbances. The principal conditions which may give rise to important disturbances on a power system are as follows:

1. Sudden increases in load.
2. Switching operations.
3. Faults.

For a general discussion of the phenomena accompanying these various types of disturbances, reference should be made to the paper by Mr. Fortescue.

Sudden Increases in Load

The supply of power from long-distance transmission lines is usually supplemented by local steam or hydroelectric power plants. In ordinary operation, sudden increases in load do not occur except in the case of the loss of a load end generator as the result of a breaker operation. For this condition, however, the load is taken up largely by the retardation of the parallel units which initially tend to contribute power in inverse proportion to their connecting impedances. The increased demand for power will require a new position of equilibrium and before reaching it, the system on account of mechanical inertia will tend to overshoot and go out of step if the transient limit is too low. If the system withstands the first overswing, both ends of the system will usually stay in step and slow down simultaneously. The increased load will cause a reduction in system frequency and in machine voltages which will bring the governors and voltage regulators into action, tending to restore the system to normal.

Switching Operations

The switching operation most likely to be important from the standpoint of stability of a transmission system is the opening of a section of line under load. The switching out of a section of line will cause the system to seek a new position of equilibrium, and the system in moving to this new point will overswing to such an extent as to produce instability if the transient limits are too low. If the system does not pull out of step on the first overswing, it is unlikely to do so later because sufficient time will usually be available for regulators to increase the excitation of the machines.

Faults

From the standpoint of maintaining stability, faults produce most severe conditions occurring in ordinary operating experience.

Three different types of faults may occur; namely three-phase, single-phase line-to-line, and the single-phase line-to-ground. High-voltage transmission systems are normally designed with neutral grounded and with relatively large clearances between conductors. There is a distinct tendency to employ single circuit tower lines and horizontal spacing of conductors on account of ice conditions. Greater attention is being given to substation layout in order to minimize the possibility of three-phase and single-phase line-to-line

faults. These considerations indicate that the occurrence of any type of fault other than the single-phase line-to-ground is relatively remote. Data on some of the high-voltage transmission circuits indicate that over 90 per cent of the faults that have occurred were from line to ground. In view of these facts, it appears that the layout should be such as to provide a reasonable margin of stability in the case of single-phase line-to-ground faults, but that it is not essential in the case of three-phase and single-phase line-to-line faults.

A fault on a transmission line will normally give rise to three circuit conditions; namely, the original condition before the fault, the condition during the fault, and the condition after the fault is cleared; and in addition another intermediate step if more than one breaker is required to clear the fault. The time interval between these changes in circuit conditions is insufficient for the system to readjust itself, consequently the changes may occur at such times as to augment the magnitude of the system oscillation. The description of the way in which the opening of a breaker to clear a line-to-neutral fault may give rise to very large system oscillations, is given in the paper by Mr. Fortescue previously referred to.

Studies of faults should not be limited to the high-voltage lines alone, but should include the distribution system and also the low-voltage bus at generating stations or at substations.

Static and Artificial Stability

In previous papers on transmission stability the subject of static stability has received most consideration. The published methods for determining the static stability limits have employed the assumption of constant field current in synchronous machines. It is to be noted that the limits so calculated are dependent only upon inherent characteristics of the machines and the other parts of the system. E. B. Shand pointed out the theoretical possibility of maintaining a condition of "artificial" stability in which the inherent static limits could be exceeded by operation of regulators and exciters. It was then generally believed and at that time not contradicted that the speed of commercial regulators and exciters was insufficient to permit the attainment of artificial stability on actual power systems. Adequate methods of transient analysis were not then available, and only by means of transient analysis or tests as on a miniature system, is it possible to prove that artificial stability may be obtained on commercial systems. Artificial stability may be defined as the condition of stable operation of power systems which is attainable only through the operation of the automatic voltage regulators and exciters. The time available for the functioning of this apparatus is dependent upon the rate of change of rotor position and the time constants of machines. The natural period of mechanical oscillation of a power system under light load conditions is of the order of a second or less, but in the vicinity of the static limit the natural period becomes longer. At the static limit the time constants of machines become the controlling factors in determining rotor movements. On this account sufficient time may be available for important changes in excitation as a result of the operation of voltage regulators.

Artificial stability can best be considered as a series of periodic transients and for this reason will be investigated by the methods of transient analysis. Calculations were made to show the possibility of obtaining a condition of artificial stability on systems equipped with commercial apparatus by considering the simple case of a generator and motor connected through a reactance tie. A load in excess of the static limit at normal terminal voltage and with constant excitation was assumed. The angle between rotors was arbitrarily increased by a small amount and calculations were made of the resulting oscillation taking into account the transients in machine fluxes and the effects of

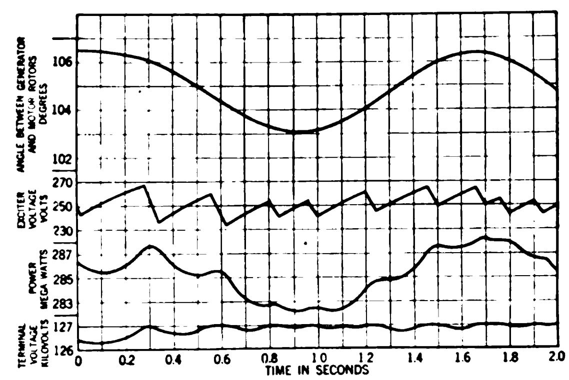

Fig. 13—The Effect of the Excitation System in Maintaining Artificial Stability

exciters and regulators and also the mechanical movements of rotors. The results of the calculations are given in Fig. 13 which indicates the possibility of securing artificial stability by the use of commercial regulators and exciters. The significant thing to note is the fact that the mechanical oscillation was so slow that the voltage regulator had time to open and close several times during an oscillation.

Analysis of Stability Tests

Cooperative stability tests were made during the early part of 1925 on the transmission system of the Pacific Gas & Electric Company as described in a companion paper by Mr. Roy Wilkins. Such tests furnish accurate information as to the operation of a system at times of disturbances and are valuable for planning future expansion. In addition, these tests which were the first of their kind, afford an opportunity to check methods of calculations and to analyze test results on an actual transmission system.

These tests are described in detail in the companion paper by Mr. Wilkins. The present discussion will be restricted to the comparison of test results and calcula-

tions. Two representative tests, one a switching operation and the other a single-phase fault, were selected for analysis.

Switching Operation

The layout of the part of the Pacific Gas & Electric Co. system involved in these tests is indicated in Fig. 14. One transmission line was operated at "110 kv." and the other at 220 kv. In test No. 12, the one selected for analysis, a switching operation was performed by opening the high voltage breaker in the 220-kv. line at the Pit River No. 1 powerhouse, transferring all of the load to the 110-kv. line. A relatively severe switching disturbance is produced in this manner as the load on the 110 kv. line is increased to over 300 per cent of the initial value.

The application of the methods of calculation previously described to the particular problem will now be discussed. The load end network consists of the 110-kv. and lower voltage distribution system, connected loads and local generators and the synchronous condensers at the Vaca-Dixon substation. This type of network may be considered as involving two sources of e. m. f. having a fixed angular relation, and a shunt impedance load and may be analyzed by the use of one of the equivalent "load end networks." The supply end network involves three power plants in parallel, Pit River No. 1, Hat Creek No. 1 and No. 2. Since Hat Creek No. 1 and No. 2 are very close together and their electrical and mechanical characteristics are similar they can be considered as one unit but due to the difference in impedance and inertia effects the Hat Creek plants cannot be combined in this manner with the Pit River No. 1 plant. This necessitates a set-up consisting of two salient pole machines at the supply end and a single equivalent machine at the load end with a shunt impedance branch representing non-synchronous load. The solution is then obtained by the step-by-step method, assuming constant gate opening for the supply end, constant direct component of voltage at the supply end generator, and constant internal voltage at the load end machines.

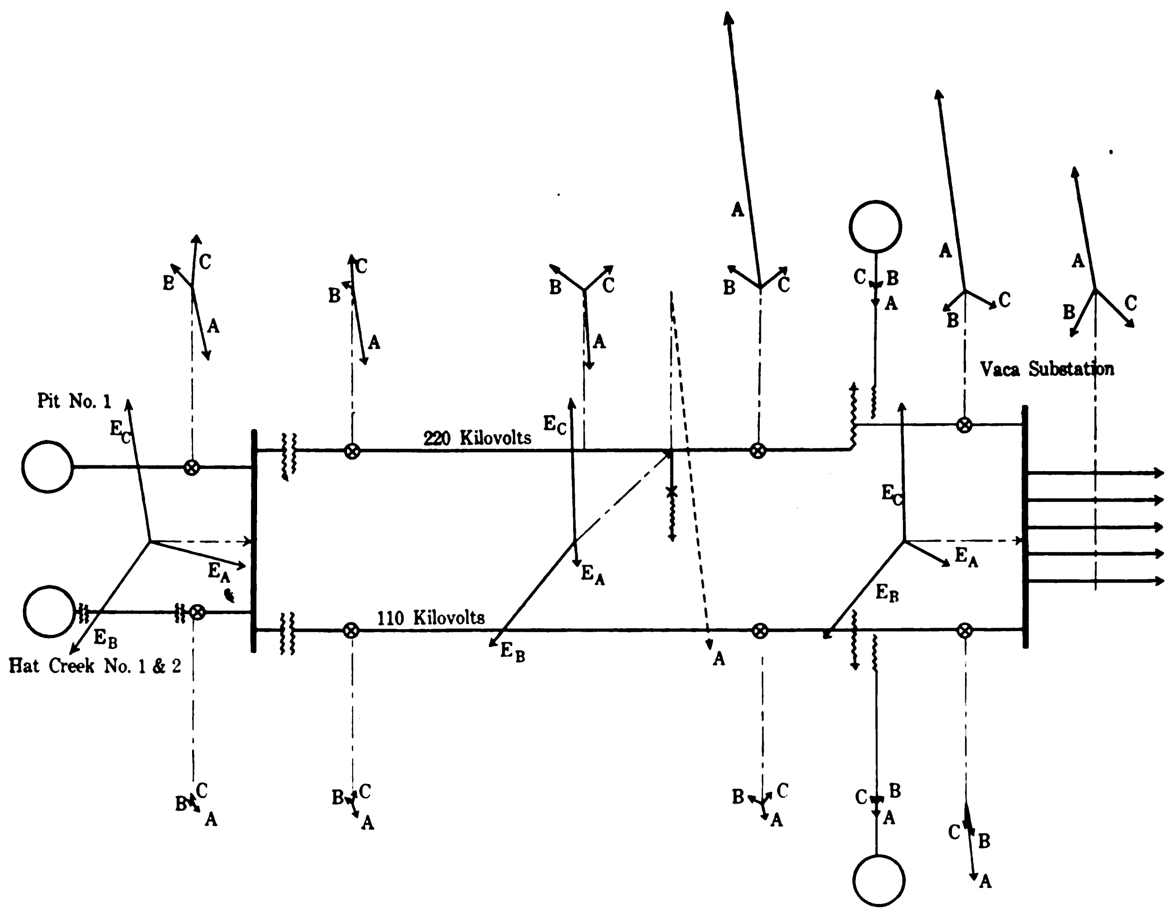

Fig. 14—Voltage and Current Distribution on Transmission System of Pacific Gas & Electric Company

With a single-phase fault to ground on 220-kv. line near Vaca substation—calculated. Voltage 30,000 volts per in.; current, 500 amperes per in., 110-kv. base

Results of the calculations of the switching operation are shown by a number of curves of power, voltage and angle plotted as functions of time from the beginning of the disturbance. In the curves of Fig. 15 are shown the calculated and observed values of power measured at Pit River No. 1. Similar curves for the generator voltage at Pit River No. 1 and the 110-kv. bus voltage at Vaca are given in Fig. 16. Fig. 17 shows the in-

stantaneous observed and calculated angles between the rotor of the Pit generator and the voltage of the 110-kv. bus at Vaca.

It will be noted that the curves show good agreement between calculated and observed values as to general magnitude and trend. It should be explained at this time that the breaker did not open the circuit completely at the beginning of the switching disturbance. This accounts for the time displacement of about 0.2 seconds in the observed results and also for the fact that the observed oscillation is of somewhat smaller magnitude.

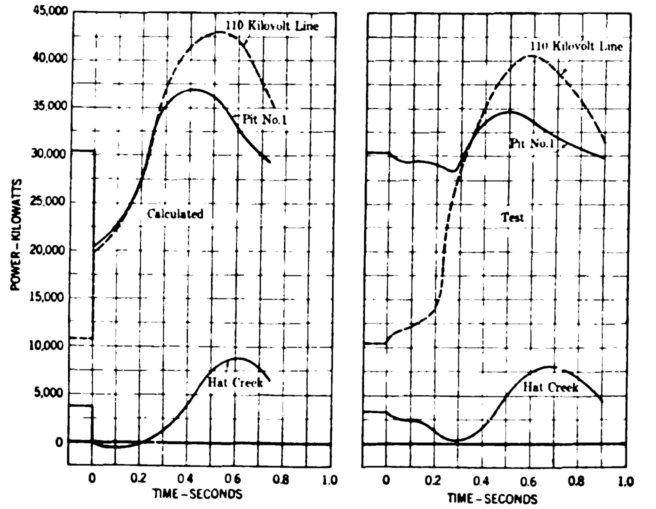

FIG. 15—COMPARISON OF TESTS AND CALCULATIONS OF POWER-OPENING ONE LINE

SINGLE-PHASE FAULT TO GROUND

The system layout for the single-phase fault to ground was the same as for the switching test previously described. The fault was applied to the 220-kv. line two towers from the Vaca-Dixon substation.

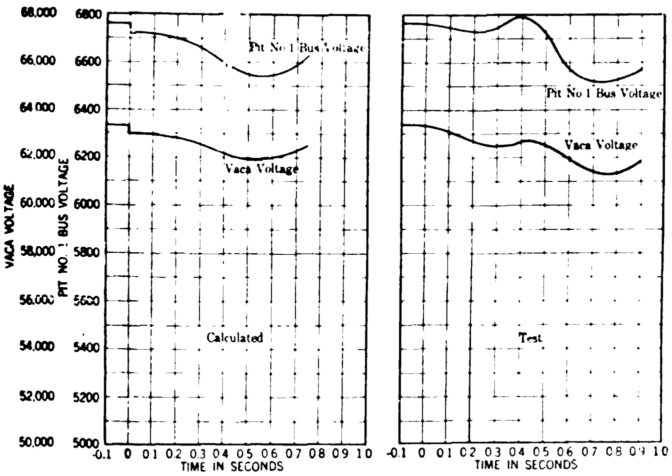

FIG. 16—COMPARISON OF TESTS AND CALCULATIONS FOR VARIATIONS IN VOLTAGE OF PIT NO. 1 BUS AND VACA 110-KV. BUS-OPENING ONE LINE

An analysis was made to determine the initial distribution of currents and voltages over the entire system by the methods outlined in Appendix II. The simplified network identical to that used for the calculations of switching operation was used with the "equivalent symmetrical network" connected at the point of short circuit. The conditions of tests were unusual in that the closely coupled transmission lines were operating at different voltages.

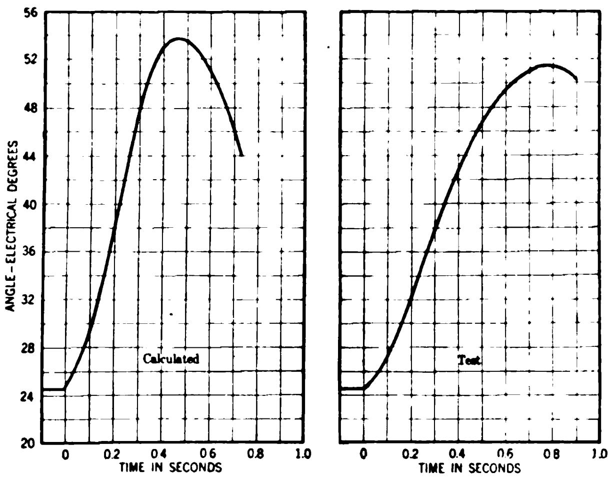

FIG. 17—COMPARISON OF TESTS AND CALCULATIONS OF ANGLE BETWEEN VACA BUS VOLTAGE AND ROTOR OF PIT NO. 1 GENERATOR,—OPENING ONE LINE

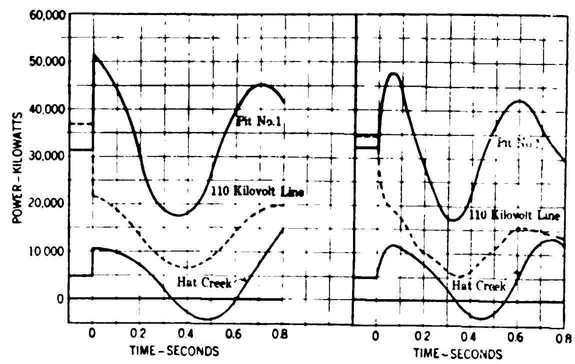

FIG. 18—COMPARISON OF TESTS AND CALCULATIONS OF POWER—CLOSING ONE LINE

Tests were also made and the transients recorded when the same breaker was closed. The results of tests and calculations of power variations for this condition are shown in Fig. 18. In this case the effect of the non-simultaneous action of the different poles does not enter, and a very close check is obtained.

TABLE V

COMPARISON OF MEASURED AND CALCULATED INSTANTANEOUS SYMMETRICAL VOLTAGES AND CURRENTS FOR FAULT TO GROUND AT VACA-DIXON SUBSTATION

	Measured	Calculated
1. Residual current in circuit breaker at Vaca	1020	1130
2. Voltage, *A* phase at Vaca	60000	59300
3. Residual voltage, 110-kv. bus at Vaca	14200	13300
4. Residual current in 220-kv. line at Pit. No. 1	140	138
5. Current, *B* phase, 220-kv. line at Pit No. 1	235	280
6. Current, *A* phase, Pit No. 1 generator*	2780	4150
7. Voltage, *A* phase, Pit No. 1 generator	4840	4996
8. Current *A* phase, 110-kv. line low side at Pit No. 1	1070	1030

*Discrepancy unexplained.

The results of calculations are shown in Fig. 14 which gives the vector distribution of the currents and voltages at different points in the system. In this figure, all the vectors are given on a common voltage basis of 110 kv., and to obtain the actual values of current and voltages in any particular part of the circuit it is necessary to take into consideration the transformer ratios and phase shifts due to the star-delta transformations. The diagram assumes the normal direction of power flow from the Pit end toward the load. The fault actually occurred on Phase *B* but, for convenience in calculation, it was assumed to occur on Phase *A*. It will be noted that at the time of fault the negative phase sequence current supplied from the condensers at Vaca are greater than the positive sequence components. The pronounced distortion of the current vectors is due largely to the low value of the transmitted load at the time of the tests.

In Table V is given the comparison of calculated voltages and currents with the corresponding quantities observed during the tests. The calculated values are based on the instantaneous symmetrical value of short circuit current and the test results are based on the values during the fourth cycle after the application of the fault. The close agreement considering the factors involved serves as a sufficient check upon the general method.

Methods of Increasing Stability

The most evident method of increasing the stability limit of a transmission system for a given voltage is to decrease the series impedance. This may be accomplished by the use of:

1. Additional circuits.
2. Lower frequency.
3. Percy Thomas split conductor.
4. Lower transformer impedance.

Another important general method for increasing the power stability of a transmission system is to employ measures to maintain or increase terminal voltages. This may be accomplished by the use of the following methods:

1. Machines of special characteristics.
2. Compensated machines.
3. High speed excitation.
4. Intermediate condenser stations.
5. Shunt reactors.
6. Additional tie lines at the receiver end of the system.

The layout of a transmission system may be modified so as to limit the magnitude of short-circuit currents. This can be accomplished by the use of reactors or transformers, and the avoidance of the bussing arrangements ordinarily employed. This method is open to the objection that it is not sufficiently flexible to meet the requirements of changing operating conditions.

Preliminary investigations of governor characteristics also indicate that certain modifications would be quite effective in maintaining system stability.

These general methods for increasing stability together with a certain amount of supporting test data are discussed in more detail in the unabridged paper.

The authors wish to take this opportunity to express their appreciation of the cooperation and assistance of the engineers of the Pacific Gas & Electric Company—especially Messrs. J. P. Jollyman and Roy Wilkins—in affording opportunity of investigating stability conditions on a large, high-voltage power system. In addition, they also wish to acknowledge the assistance of their associates, particularly Mr. S. B. Griscom, who has made important contributions to the methods presented.

Conclusions

Stability is an important limitation in the transmission of large amounts of power per circuit over long distances. Provision for securing stability should be made for both steady state and the more frequently occurring abnormal conditions. The limiting condition, as indicated by these studies, is the single-phase fault to ground, followed by the disconnection of the faulty section of line. Normal switching operations, except in a few special cases, will not give rise to severe system disturbances. Under emergency conditions in which a large proportion of the lines are out of service, the system may approach the limit of static stability.

The static limit of systems operating without voltage regulators is determined by the inherent characteristics of the machines and lines. With voltage regulators, a condition of artificial stability may be obtained on commercial systems and the machines tend to operate on a constant voltage rather than a constant excitation characteristic.

Methods have been presented for the analysis of stability for the various conditions that arise in system operation. The principal new features are the treatment of machine characteristics, the simplification of load end networks, and the handling of single-phase faults.

Increase in the power or stability limits may be obtained by the use of a number of methods discussed in the paper. Of particular importance are high-speed excitation and machines of special design capable of delivering a relatively large increase in lagging kv-a. with drop in voltage. Mention should also be made of special governor control.

The underlying requirement for securing stability of a system delivering a large amount of power, is one of obtaining good regulation of line and terminal equipment. Improved stability conditions may be obtained by methods providing good regulation, either inherently as by compensated machines, or automatically by high-speed excitation systems.

The use of intermediate condenser stations permits the transmission of the largest amount of power per circuit. The effectiveness of this scheme may be con-

siderably increased by the use of specially designed condensers or compensated condensers, or by high-speed excitation.

Stability is important not only for high-voltage long-distance transmission, but also for low-voltages and interconnections where relatively large amounts of power are handled per circuit.

The method of operating a power system, including setting of relays and circuit breakers, sequence of switching operations, governor adjustments, etc., has an important bearing on stability. An analysis of these factors as they affect stability should lead to the selection of the operating method which would minimize system disturbances.

Heaviside's Proof of His Expansion Theorem

BY M. S. VALLARTA[1]

Associate, A. I. E. E.

Synopsis.—*Heaviside's proof of his celebrated Expansion Theorem, found scattered in his "Electrical Papers," is reconstructed. It is based upon his so-called "conjugate theorem," also discovered independently by Routh, which establishes a relation between any two normal modes of oscillation of a dynamical system. Heaviside's argument applies to systems having finite number of degrees of freedom and no repeated or null roots of the determinantal equation of the system. The relation between Heaviside's, Carson's and Wagner's proofs is also pointed out.*

* * * * *

LET an arbitrary electric network be given and suppose a unit constant voltage is impressed at a certain instant. Then the determination of the d-c. transient and of the steady state which follows consists in finding an integral of a linear differential equation of the nth order, with constant coefficients and satisfying n initial conditions. By ordinary methods the determination of the arbitrary integration constants using the initial conditions is, as a rule, extremely laborious, except perhaps in the simplest type of circuits; therefore, a formula giving directly the transient current, without requiring the determination of integration constants, would mean a considerable advance in circuit theory. If further it is realized that when the d-c. transient and the corresponding steady state are both known, the behavior of the network under all common types of impressed voltages is also known[2], the importance of such a formula becomes at once evident.

In his celebrated Expansion Theorem, Oliver Heaviside gave just such a formula. In accordance with his somewhat eccentric habits of thought, he merely wrote down his final result on page 127 of the second volume of his "Electromagnetic Theory," without giving a proof, even without the slightest hint to his previous investigations leading to this result. This seems to have eventually given rise to the impression that Heaviside did not prove his Expansion Theorem, but rather found it in some obscure fashion, peculiar to him, by considerations which might not be of the nature of a logical proof. Thus J. R. Carson in his latest paper on circuit theory[3] writes that "the Expansion Theorem was stated by Heaviside without proof; how he arrived at it will probably always remain a matter of conjecture," while K. W. Wagner[4] writes, "Heaviside gibt die Formel ohne Beweis, ja selbst, ohne einen solchen anzudeuten" (Heaviside gives the formula without proof; what is more, without giving an indication of one) and exactly the same view is expressed in a recent paper by L. Casper[5]. Now, although no proof of the Expansion Theorem, and even no indication of such, is given in the "Electromagnetic Theory," numerous scattered investigations which might lead up to this remarkable formula are found in Heaviside's "Electrical Papers" and also in many of his published writings; therefore, the possibility that he might have given a proof of his Expansion Theorem was recognized by some writers, among them V. Bush[6], L. F. Woodruff[7] and the present author[8]. It was not until quite recently, however, that a reconstruction of Heaviside's own proof of his Expansion Theorem was possible.

The first to examine Heaviside's investigations leading to the Expansion Theorem and recognize their interest, extreme generality and correctness, was T. J. Bromwich[9], who, in an exhaustive paper published in 1916, but read in 1914, not only gave an independent

derivation of the Expansion Theorem, similar to Wagner's[10], but also showed with extreme clearness the connection between Heaviside's argument and those methods of derivation which, like Bromwich's and Wagner's make use of contour integrals to solve the dynamical equations.

Heaviside's derivation of his Expansion Theorem is based on the so-called "conjugate theorem" which we now proceed to establish. The conjugate theorem was probably first discovered by Routh[11], but Heaviside was undoubtedly unaware of Routh's results, his methods are completely independent and, further, his results are easier to state than those of Routh.

Consider an electric network of n degrees of freedom (n currents required to specify the circuit completely at any one instant). It is well known that such a network is the exact analogue of a dynamical system of n degrees of freedom in which the forces of reaction are proportional to the displacements from equilibrium or zero configuration (*i. e.*, elastic forces of Hooke type) and the forces of resistance are proportional to the velocities. In this electromechanical analogy, inductance is equivalent to coefficient of inertia, the reciprocal of capacity to the elastic coefficient and resistance to the coefficient of dissipation or frictional coefficient; electromotive force corresponds to applied force, current to velocity and charge to displacement. This fact has been already utilized in the analysis of circuit problems by mechanical models and conversely by Doherty and many others.

The equations of motion of a dynamical system of the type specified above are well known to be[12]:

$$\left.\begin{array}{l}
\left(C_{11}\dfrac{d^2}{d\,t^2} + B_{11}\dfrac{d}{d\,t} + A_{11} \right) x_1 + \;.\;.\;.\;. \\
\qquad + \left(C_{1n}\dfrac{d^2}{d\,t^2} + B_{1n}\dfrac{d}{d\,t} + A_{1n} \right) x_n = F_1 \\
\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;. \\
\left(C_{n1}\dfrac{d^2}{d\,t^2} + B_{n1}\dfrac{d}{d\,t} + A_{n1} \right) X_1 + \;.\;.\;. \\
\qquad + \left(C_{nn}\dfrac{d^2}{d\,t^2} + B_{nn}\dfrac{d}{d\,t} + A_{nn} \right) x_n = F_n
\end{array}\right\} \qquad (1)$$

In this system of linear differential equations, $C_{\kappa\kappa}$, $B_{\kappa\kappa}$ and $A_{\kappa\kappa}$ are the coefficients of inertia, dissipation and elasticity of the kth branch, x_κ the displacement of the kth branch and $C_{\kappa j}$, $B_{\kappa j}$, $A_{\kappa j}$ the coefficients of inertia, dissipation and elasticity between the kth and the jth branches. $F_1, F_2 \;.\;.\;.\;.\; F_n$ are the external forces acting on the corresponding branches.

Equations (**1**) form the starting point of Heaviside's argument[13]. On account of the precise analogy between the electric network and the mechanical system, it is immaterial whether use is made of electrical or mechanical entities and it is permissible to change from the network to the mechanical system if only the right equivalents are used. Let Q be the rate at which energy is dissipated in the system, due to the presence of frictional forces in it, U the potential energy of the elastic forces and T the kinetic energy. The power transferred to the system by the applied forces is $\sum_{k=1}^{n} F_\kappa\,\dot{x}_\kappa$ ($\dot{x}_\kappa = d\,x_\kappa/d\,t$), so the conservation of energy gives,

$$\sum_{k=1}^{n} F_\kappa\,\dot{x}_\kappa = Q + \dot{U} + \dot{T} \qquad (2)$$

which says that the power delivered by the applied forces is equal to the energy dissipated, plus the rate of increase of the kinetic energy of the system, plus the rate of increase of the stored elastic energy. Q, U and T are defined in terms of the variables $x_1 \;.\;.\;.\;.\; x_n$ which determine the state of the system at a given instant by the expressions,

$$\left.\begin{array}{lll}
2\,T = \sum_{i,j=1}^{n} C_{ij}\,\dot{x}_i\,\dot{x}_j & & (C_{ij} = C_{ji}) \\
Q \;\;= \sum_{i,j=1}^{n} B_{ij}\,\dot{x}_i\,\dot{x}_j & & (B_{ij} = B_{ji}) \\
2\,U = \sum_{i,j=1}^{n} A_{ij}\,x_i\,x_j & & (A_{ij} = A_{ji})
\end{array}\right\} \qquad (3)$$

The symmetrical conditions imposed on the coefficients $A_{ij} = A_{ji}$, $B_{ij} = B_{ji}$, $C_{ij} = C_{ji}$ mean that there are no forces of gyrostatic origin, also no forces not derivable from a potential-energy function. Such relations are also assumed to be satisfied in the corresponding electric network, thus excluding thermionic devices, etc.

It is well known that the reduced system of differential equations obtained from equations (**1**) *i. e.*, the system obtained by putting all the impressed forces equal to zero, admits an exponential solution of the type $x_\kappa = X_\kappa\,e^{pt}$, X_κ and p being real, imaginary or complex constants to be determined. Such solutions are called the *normal* solutions. The substitution $x_\kappa = X_\kappa\,e^{pt}$ transforms (**1**) from a system of linear differential equations with constant coefficients, with time as independent variable, to a system of algebraic equations with p as unknown. It is further known that the condition that the system in question have a solution is that the determinant of the coefficients shall vanish. This determinant is defined by

10. Wagner's proof of the Heaviside theorem appeared as a part of his paper already quoted (l. c. footnote 4) on March 21, 1916. Bromwich's paper was read on March 12, 1914, received April 22, 1916, published in 1916.

11. "Rigid Dynamics," Vol. 2, Articles 383, 384; 1892.

12. For a full discussion of these equations and their derivation see for example Whittaker's "Analytical Dynamics," p. 177, Cambridge, 1917.

13. "Electrical Papers," Vol. 2, p. 202. First published in his paper "On the Self-Induction of Wires," Parts 3 and 4, Philosophical Magazine, Vol. 22, pp. 332-352 and pp. 419-442, October and November, 1886; see p. 335 and p. 426.

$$D(p) = \begin{vmatrix} A_{11}+B_{11}\,p+C_{11}\,p^2 \;\ldots\; A_{1n}+B_{1n}\,p+C_{1n}\,p^2 \\ \cdots\cdots\cdots\cdots\cdots\cdots \\ A_{n1}+B_{n1}\,p+C_{n1}\,p^2 \;\ldots\; A_{nn}+B_{nn}\,p+C_{nn}\,p^2 \end{vmatrix} \quad (4)$$

$D(p) = 0$ is then known as the determinantal equation of the system. If p_κ is a root of $D(p) = 0$, p_κ also satisfies the original equations (1). For each root $p = p_\kappa$ of the determinantal equation, suppose we find a solution, $l_1, l_2, l_3 \ldots l_n$ for the equations,

$$\left.\begin{array}{l} (A_{11} + B_{11}\,p_\kappa + C_{11}\,p_\kappa^2)\,l_1 + \ldots \\ \quad + (A_{1n} + B_{1n}\,p_\kappa + C_{1n}\,p_\kappa^2)\,l_n = 0 \\ \cdots\cdots\cdots\cdots \\ (A_{n1} + B_{n1}\,p_\kappa + C_{n1}\,p_\kappa^2)\,l_1 + \ldots \\ \quad + (A_{nn} + B_{nn}\,p_\kappa + C_{nn}\,p_\kappa^2) = 0 \end{array}\right\} \quad (5)$$

If then the initial displacements u_κ and the initial velocities v_κ are adjusted so that,

$$\left.\begin{array}{l} \dfrac{u_1}{l_1} = \dfrac{u_2}{l_2} = \ldots = \dfrac{u_n}{l_n} = A \\[2ex] \dfrac{v_1}{l_1} = \dfrac{v_2}{l_2} = \ldots = \dfrac{v_n}{l_n} = A\,p_\kappa \end{array}\right\} \quad (6)$$

a possible solution of the system (1) is given by,

$$x_1 = A\,l_1\,e^{pKt}\; x_2 = A\,l_2\,e^{pKt}\; x_n = A\,l_n\,e^{pKt} \quad (7)$$

that is, by placing,

$$X_1 = A\,l_1, \quad X_2 = A\,l_2 \quad X_n = A\,l_n \quad (8)$$

The constant A therefore fixes the amplitude of the displacement. Further, on account of the linearity of the equations, $x_r = \sum_\kappa A\,l_\kappa\,e^{pKt}$ is also a solution, the summation being over the roots of $D(p) = 0$. But it is by no means evident that the $2\,n$ equations (6), which determine the amplitude of the normal solutions, are themselves algebraically capable of solution; in fact examples can be given where the normal solutions are not algebraically independent. The most direct proof that the constants A can be found is to express them in terms of the initial values of displacements and velocities. This is done by the Heaviside-Routh conjugate theorem.

Coming back now to Heaviside's argument, suppose that all the impressed forces vanish, so that no energy can be transferred to the system, while the stored energy, due to the elastic connections of the system, is dissipated irreversibly through frictional forces. Let p_1 and p_2 be any two different roots of $D(p) = 0$, satisfying equations (1), so that $x_1 = X_1\,e^{p_1t}$, $x_2 = X_2\,e^{p_2t}$ are solutions of (1). Let further Q_1, U_1, T_1 be the dissipation, kinetic and potential-energy functions corresponding to the normal solution p_1 *i. e.*, to $x_1 = X_1\,e^{p_1t} \ldots\ldots x_n = X_n\,e^{p_1t}$. Then the conservation of energy gives,

$$Q_1 + \dot{U}_1 + \dot{T}_1 = 0 \quad (9)$$

but since,

$$\dot{U}_1 = \frac{1}{2}\,p_1 \sum A_{ij}\,x_i\,x_j + \frac{1}{2}\,p_1 \sum A_{ij}\,x_i\,x_j = 2\,p_1\,U_1 \quad (10)$$

and, likewise,

$$\dot{T}_1 = 2\,p_1\,T_1 \quad (11)$$

therefore,

$$Q_1 + 2\,p_1\,(U_1 + T_1) = 0 \quad (12)$$

In the same way, let Q_2, T_2, U_2 be the dissipation, kinetic and potential-energy functions corresponding to the normal solution p_2, *i. e.*, to $x_1' = X_1\,e^{p_2t} \ldots\; x_n' = X_n\,e^{p_2t}$. We have, precisely as above,

$$Q_2 + 2\,p_2\,(U_2 + T_2) = 0 \quad (13)$$

Now, since p_1 is a root of the determinantal equation, and p_2 is also a root of the determinantal equation, therefore $x_1, x_2 \ldots x_n$ and $x_1', x_2', \ldots\ldots x_n'$ are both solutions of the original system of equations (1). If now, following a nomenclature suggested by Bromwich, we define the relative kinetic energy, the relative potential energy and the relative dissipation of the two normal modes of oscillation p_1, p_2, by means of the expressions

$$\left.\begin{array}{l} \dfrac{1}{2}\,Q_{12} = \sum\limits_{i,j=1}^{n} B_{ij}\,\dot{x}_i\,\dot{x}_j' \\ U_{12} = \sum\limits_{i,j=1}^{n} A_{ij}\,x_i\,x_j' \\ T_{12} = \sum\limits_{i,j=1}^{n} C_{ij}\,\dot{x}_i\,\dot{x}_j' \end{array}\right\} \quad (14)$$

we find again from the conservation of energy that

$$\frac{1}{2}\,Q_{12}+p_2\,U_{12}+p_1\,T_{12}=0,\; \frac{1}{2}\,Q_{12}+p_1\,U_{12}+p_2\,T_{12}=0 \quad (15)$$

whence, by subtraction

$$(p_1 - p_2)\,(U_{12} - T_{12}) = 0 \quad (16)$$

and therefore, $U_{12} = T_{12}$, which is the so-called conjugate theorem. It says in words that the relative kinetic energy of two normal solutions (two normal modes of motion) is equal to the relative potential energy of these two normal solutions. It is to be noted quite carefully that the above reasoning holds only for the case of different roots, $p_1 \neq p_2$.

Heaviside also shows that the conjugate theorem holds for the electromagnetic system expressed by Maxwell's equations. It is to be observed in this connection that the equations (1) which correspond, as already explained, to the electric network, are consistent with the Maxwell circuital laws provided only that the displacement current is negligible compared to the conduction current[14], therefore any argument based on these equations applies to the dynamical system under consideration, but not conversely. The proof is quite simple, but will not be given here[15].

Now let T_{r0}, U_{r0}, be the relative kinetic energy of the normal mode corresponding to the root p_r with respect to the *initial* velocities and displacements, T_{rr}, U_{rr}, the kinetic energy of the normal mode under consideration with respect to itself. T_{r0}, U_{r0}, T_{rr}, U_{rr}, are defined by the expressions,

14. See for example M. Abraham, "Theorie der Elektrizität," Vol. 1, pp. 227-260, Leipzig. 1920.

15. Heaviside, "Electrical Papers," Vol. 2, p. 203-204.

$$\left.\begin{array}{ll} T_{r0} = \sum\limits_{i,j=1}^{n} C_{ij}\, p_r\, l_i\, v_j & T_{rr} = \sum\limits_{i,j=1}^{n} C_{ij}\,(p_r\, l_i)\,(p_r\, l_j) \\ U_{r0} = \sum\limits_{i,j=1}^{n} B_{ij}\, l_i\, u_j & U_{rr} = \sum\limits_{i,j=1}^{n} B_{ij}\, l_i\, l_j \end{array}\right\} \quad (17)$$

whence it follows that $U_{rr} = 2\,U$, $T_{rr} = 2\,T$ (cf. equations (3)). Now if coefficients $B_K = A\, l_K$ are found as outlined above, so that,

$$\left.\begin{array}{l} U_{r0} = \sum\limits_{k=1}^{n} B_K\, U_{Kr} \\ T_{r0} = \sum\limits_{k=1}^{n} B_K\, T_{Kr} \end{array}\right\} \quad (18)$$

then

$$B_r = \frac{U_{r0} - T_{r0}}{U_{rr} - T_{rr}} \text{ and } A = \frac{T_{10} - U_{10}}{T_{11} - U_{11}} \quad (19)$$

because, by the conjugate theorem, all the differences $U_{rs} - T_{rs}$ vanish.[16]

Let us now suppose that all the applied forces save one, F_1, are zero. On account of the linearity of the equations, this is just as general as inserting forces $F_1, F_2, \ldots F_n$ in each one of the n branches. Let F be an exponential, real, imaginary or complex function of time. Then, for any x,

$$x_K = \frac{F_1}{Z\,(p)} \quad (20)$$

$Z\,(p)$ being a function of p obtained from equations (1) by elimination of all the x's except the one desired. It is in general given by the ratio of two determinants. Now,

$$F_1 \frac{d\, x_K}{d\, p} - x_K \frac{d\, F_1}{d\, p} = - x_K^2 \frac{d}{d\, p} \frac{F_1}{x_K} = - x_K^2 \frac{d\, Z}{d\, p} \quad (21)$$

and, by the conjugate theorem,

$$2\,(T - U) = x_K^2 \frac{d\, Z}{d\, p} \quad (22)$$

Heaviside[17] now directs his attention to the electric network corresponding to the mechanical system so far considered and reasons in terms of voltage and current instead of force and velocity or displacement. It has been already shown that the internal connections of the system, *i. e.*, the coefficients A, B, C, determine how the variables chosen to fix the system should vary in order that the resultant system be normal and that the amplitude of the normal modes of oscillation is in turn determined by the conjugate theorem. The actual current and the actual voltage are then represented by sums of normal solutions (cf. equations (7) and (8))

$$V_K = \sum_j A_j\, u_j\, e^{p_j t} \qquad I_K = \sum_j A_j\, w_j\, e^{p_j} \quad (23)$$

the summations being over the roots of the determinantal equation $Z\,(p) = 0$. The coefficients are, as stated, determined by the conjugate theorem.

In order to find the current due to a constant applied voltage, Heaviside makes use of the following argument: Suppose that instead of inserting a constant voltage e, a condenser of capacity C is inserted in the circuit at the same point; by allowing C to increase indefinitely the effect of a constant applied voltage is obtained. This is an essential point, as it reduces the problem on hand to a subsidence problem, with no external forces. Therefore, the current can still be obtained as a sum of normal solutions. For suppose that the condenser C is inserted in the network at a given point and at a certain instant, there being no current and no voltage in any of its branches at that instant. The problem is then to find the subsidence to equilibrium of a system under its own internal stored energy. The conjugate theorem therefore holds. Let the algebraic function expressing the relation between a voltage F_K in branch K and the current I_K in the same branch be $Z\,(p)$ (see Equation (20)); suppose now that the condenser C is inserted in the same branch K and let the corresponding function be $Z_1\,(p)$. Remove the voltage F_K, charge the condenser and switch it on branch K. We have now the subsidence problem, to be solved through the same process as before, by making use of the known properties of normal functions and the conjugate theorem.

Let w_j, u_j, be the normal mode of oscillation of current and of corresponding voltage in the branch under consideration where the condenser is inserted. Since the current is equal to the rate of decrease of charge in the condenser, therefore

$$w_j = - C\, \dot{u}_j = - C\, p_j\, u_j \quad (24)$$

because u_j is a normal coordinate. Initially, that is, at the instant the condenser is switched on its initial voltage V is $V = \sum_j A_j\, u_j$ and $\sum A_j\, w_j = 0$, as there is no current[18]. The electric (potential) energy stored in the condenser is $\frac{1}{2}\, C\, V\, u_j$, so by the conjugate theorem

$$C\, V\, u_j = 2\,(U - T)\, A_j \quad (25)$$

U, T being the electric and magnetic energies of the normal mode. But we have also, by the conjugate theorem

$$2\,(U - T) = - w_j^2 \left.\frac{d\, Z_1}{d\, p}\right|_{p = p_j} \quad (26)$$

Therefore by (25) and (26)

$$A_j = - \frac{C\, V\, u_j}{w_j^2 \left.\dfrac{d\, Z_1}{d\, p}\right|_{p = p_j}} \quad (27)$$

16. See Heaviside's "Electrical Papers," Vol. 1, p. 523, or "The Electrician," November 27, 1885, p. 46; also Routh, l. c. footnote (11).

17. Electrical Papers, Vol. 2, p. 372; see also his paper "On Resistance and Conductance Operators, etc," in Philosophical Magazine, Vol. 24, pp. 479-502, 1887. See p. 501.

18. The initial current is zero because A_{ij}, B_{ij}, C_{ij} are all finite.

Now substitute u_j from (24) in (27), the result is

$$w_j A_j = V \left(p_j \frac{d Z_1}{d p} \bigg|_{p = p_j} \right)^{-1} \quad (28)$$

and substituting in the second of (23):

$$I_K = \sum_j \frac{V e^{p_j t}}{p_j \, d Z_1 / d p \, \big| \, p = p_j} \quad (29)$$

which is the subsidence current. Now to get the effect of a constant applied voltage, let C be increased indefinitely, keeping V constant. This is the same as though the circuit were connected to a source of infinite energy. Now the structure of $Z_1(p)$ may be readily seen to be such that

$$\lim_{C \to \infty} Z_1(p) = Z(p) \quad (30)$$

and when C increases indefinitely one root of $Z_1(p) = 0$ approaches zero, because the condenser in the branch K introduces in the determinantal equation a term which varies inversely with C. It follows that when C increases indefinitely

$$p_j \frac{d Z_1}{d p} \bigg|_{p = p_j} = p_j \frac{d Z}{d p} \bigg|_{p = p_j} \text{ for all roots except } p = 0,$$

and for $p = 0$ (31)

$$\lim_{C \to \infty} \left(p \frac{d Z}{d p} \right)_{p = 0} = Z(0) \quad (32)$$

therefore, finally

$$I_K = \frac{V}{Z(0)} + \sum_j \frac{V e^{p_j t}}{p_j \dfrac{d Z}{d p} \bigg|_{p = p_j}} \quad (33)$$

which is the Heaviside Expansion Formula.

Two points are to be noted in connection with Heaviside's derivation. The first is that his method of reasoning applies only to the case where the determinantal equation has no null and no repeated roots, otherwise, the conjugate theorem breaks down and therefore also the expansion theorem. The second is that the proof as it stands applies only to a system with finite number of degrees of freedom.

Heaviside also gave another alternative proof of his Expansion Formula, the essential point of which is the splitting of the quotient $F_{rs}(p)/D(p)$, where $F_{rs}(p)$ is the cofactor of the element containing the coefficients A_{rs}, B_{rs}, C_{rs} in the determinant $D(p)$, into a sum of partial fractions.[19] This is also the essential point in Carson's first proof[20].

Heaviside has also tried to generalize his proof so as to apply to a system of infinite number of degrees of freedom, but his argument, while quite convincing from a physical standpoint, is not mathematical. It may be formulated analytically, but the proof of the theorem for infinite roots leads to formidable difficulties, some of which have already been examined by Bromwich[21] (l. c. footnote 9). The relation between the conjugate theorem and Wagner's method of attack has been fully treated by Bromwich and will not be taken up here.

It is almost certain that few have realized the extraordinary completeness and generality of some of Heaviside's investigations. It is in the hope of calling attention to the unexplored parts of his work, also as an effort to secure a better appreciation of his labors, that this paper has been written.

19. "Electrical Papers," Vol. 2, p. 226, where the footnote supersedes the text.

20. "On a General Expansion Theorem, etc.," *Physical Review*, Vol. 10, p. 217, 1917, also l. c. footnote (3).

21. Wagner's proof is not applicable to infinite roots as it stands, because Cauchy's residual theorem, on which his proof is based, does not apply to infinite number of poles without special investigation of the behavior of the function under the integral sign.

INSULATION IN USED MACHINES

The standards of the American Institute of Electrical Engineers and other similar rules or specifications prescribe a definite high-potential test for new electric generators and motors. Much can be said for and against subjecting insulation to a higher stress than it ever will be called upon to stand in actual operation, but at any rate the specified overpotential is a perfectly definite guide for the maker and the user of a machine. However, when it comes to a machine already in use the situation becomes quite indefinite. A used machine may be subjected to a high-potential test either as a part of periodic inspection or on special occasions—for example, after repairs to the winding or a change in connections.

Since even the best known insulation deteriorates with time, it would hardly seem rational to subject a used machine to a high-potential test of the same severity as a new machine. At the same time, when a machine is performing an important duty the operating engineer prefers to know of an impending failure in advance rather than to wait until the machine actually breaks down at an inopportune moment. To test it "destructively" is to invite such a failure, but apparently there are no reliable non-destructive physical tests to indicate the condition of insulation. Measurement of insulation resistance is not always indicative, and even a high-potential direct-current test with a kenotron may give a false assurance, since the dielectric loss is absent.

This question of dielectric tests on used machines is of considerable importance to public service companies and to users of large electric motors in various industries. With it is closely connected the problem of finding a non-destructive physical test indicative of an incipient deterioration or of the state of preservation of the insulation. The time is ripe to engage in thoroughgoing research in this direction.—*Electrical World.*

ILLUMINATION ITEMS

By the Committee on Production and Application of Light

A NEW LIGHTING ORGANIZATION IN FRANCE

A society for the improvement of illumination (Societe pour le Perfectionnement de l'Eclairage) has been organized in France by some of the leading central stations, electrical manufacturers, contractors, dealers, and others interested in the development of the electrical industry. It has its headquarters in Paris. The object of the organization is clearly set forth in a circular which, freely translated, reads as follows:

"Considerable work has been done this past year in different countries to promote the development and improvement of illumination in all fields; public lighting, industrial, commercial and residential.

"Innumerable commercial and industrial enterprises utilize electric light very poorly because no rational study has been made of the best conditions of installation. The luminous sources produce glare and harm vision, in place of lighting properly the objects or the spaces which it is intended to illuminate. It is often the same in the case of public lighting. In lighting the home, people ordinarily limit themselves to using or copying old devices without seeking to make the best of the many advantages which the use of electricity offers.

"The Society for the Improvement of Lighting (S. P. E.) proposes to collect, centralize, distribute and popularize information relative to lighting practise; to develop illuminating engineers; to conduct a campaign in favor of better lighting; to explain and to show by meetings, publications and experiments, the principles on which rational installations must be made; to study, on behalf of those who desire it, the arrangements which should be made in individual cases to obtain the maximum useful effect.

"This Society seeks no commercial profit and sells no apparatus of any kind. It places itself at the disposal of all who have need of advice or information on lighting subjects. Its advice or its information is given always gratuitously. Therefore no one need hesitate to consult it, because it has been created and organized for the purpose of popularizing better lighting."

The first six booklets which have been prepared by this organization in its campaign for better lighting present in a very forceful way, the advantages of good illumination and the need of avoiding glare. They are quite different in appearance and style than the popular advertising material here. Many lighting men in this country will follow with interest the work which the new society is doing to carry the message of good lighting to the people of France.

It is indicated that in 1925 the total amount of new financing by American public utilities, excluding steam railroads, exceeded $1,750,000,000. This figure compares with $1,500,000,000 in 1924.

LIGHTING INSTALLATIONS SHOULD BE DESIGNED FOR SUBNORMAL EYES

Intensities of illumination are generally far from adequate for perfect or "normal" eyes. To increase the intensity to the high level most suitable and economically desirable for workers with normal vision is such a formidable task that little thought has been given to that necessary for the best efficiency of workers whose vision is subnormal. Apparently it has been assumed that subnormal eyes are in an insignificant minority. However, the truth seems to be that the majority of workers' eyes are not perfect. Evidence to this effect has been accumulating of late through systematic eye examination. Furthermore, it has been found that, for seeing equally well, if possible at all with defective eyes requires a greater intensity of illumination than for normal eyes. Correcting refractive errors by means of glasses is, to some extent, equivalent to increasing the intensity of illumination; but there is enough evidence to indicate that average eyes, even if corrected by means of glasses, require more light than normal eyes to attain equal facility in seeing.

Many statistics of eye examination have been published, among the most recent being those obtained by the United States Public Health Service in two New York post offices. These are sufficient to illustrate the great prevalence of eye defects. The eyes of two thousand, five hundred employees were examined with the following results: Normal or no defects, 17.1 per cent; one refractive error or more, 73.7 per cent; one inflammatory condition or more, 14.5 per cent; one muscular unbalance or more 25.6 per cent; using glasses, 35.6 per cent. These percentages are startling, but approximately the same results have been obtained in other investigations, and a glance at the bespectacled contingent to any gathering is enough to convince one of their accuracy.

It is not surprising to those who have reached the "bifocal" stage in life that the percentage of near-sightedness and other eye defects increases as the average age of a group of workers increases. The percentage of normal eyes decreases rapidly beyond the age of forty years. In lighting practise, this means that a relatively higher intensity of illumination should be supplied in those industries where skilled labor is important, because, in general and up to a certain point, skill is acquired with age. Thus it is seen that the prevalence of defective eyes over perfect or "normal" ones makes it necessary in the practise of lighting that special consideration be accorded to them.—*Electrical World.*

The night aviator flies from Jacksonville to Miami trusting mainly to his compass save for the 70-mile stretch from Palm Beach to Miami, which is lighted. At a meeting in Fort Pierce, plans were initiated to the end that the entire 390-mile route shall become a glorious White Way.

Cleveland Has Very Successful and Well Attended Meeting

From every point of view the Regional Meeting held in Cleveland, March 18-19, was an outstanding success. An attendance of 430, intense interest in the technical papers and in the addresses by prominent men, and enjoyment of the other features distinguished this meeting. The members of the convention committee deserve the greatest praise for their efforts in planning and managing the affair.

Papers on Sectionalized Electric Drive

Sectionalized electrical drive, particularly as applied in paper mills, was the subject of the first two technical sessions which were held on Thursday, March 18, in the Hotel Cleveland, the convention headquarters. Three papers on this topic were presented and there followed a very complete discussion in which a large number of paper-mill executives and engineers took part. The discussion brought out the fact that sectional drive of paper mills is generally desirable for new mills. There were some questions as to the economic advantages of replacing mechanical drive in old mills of certain classes with electrical drive. Also there was doubt in the minds of some of the paper-mill men of the necessity for such refinements of speed regulation as those described in the papers but it was admitted that in-so-far as a better quality of paper could be produced the refinements would be justified. The three papers were: *Electrification of Paper-Making Machines*, by S. A. Staege, Westinghouse Electric & Mfg. Co.; *The Development of the Sectional Paper-Machine Drive*, by H. W. Rogers, General Electric Co., and *Sectional Paper-Machine Drive*, by R. N. Norris.

Those taking part in the discussion were: T. D. Montgomery, L. W. W. Morrow, F. C. Bowler, N. D. Paine, H. L. Sanborn, J. F. Rhodes, R. T. Kintzing, E. B. Bearce, E. B. Wright, R. S. White, C. A. Farrell, Tom Harvey, R. S. Lowry, J. H. Crossley, A. O. Spierling, H. C. Busser, W. W. Spratt, S. A. Staege, H. W. Rogers, and R. N. Norris.

Dinner, with Address by Newton G. Baker

On Thursday evening the convention dinner was held in the Hotel Cleveland. Music and a number of entertainers made this an enjoyable occasion. After the dinner A. G. Pierce, Vice-President of the Middle-Eastern District, A. I. E. E., introduced the toastmaster, C. P. Cooper, President, Ohio Bell Telephone Company, who in turn presented Mayor Marshall of Cleveland who welcomed the members in the name of the City. F. L. Hutchinson, National Secretary, A. I. E. E., responded for the Institute in a short address in which he outlined the Institute's purposes and activities. The Honorable Newton G. Baker, former Secretary of War, then gave an inspiring address on some of the major problems of American civilization. Farley Osgood, Past-President, A. I. E. E. responded for the Institute members.

Domestic Electric Refrigeration

On March 17 two addresses on electric refrigeration were given. The first of these was by C. F. Kettering, President, General Motors Research Corporation, and its title was *Some Scientific Phases of Refrigeration*. Mr. Kettering explained in a most interesting way the principles of refrigeration and their applications, as well as the requirements for producing and marketing household refrigerators. A number of interesting demonstrations helped to explain Mr. Kettering's points.

G. E. Miller, Cleveland Electric Illuminating Company, spoke on *Domestic Refrigeration from the Central-Station Point of View*. In an illustrated address he described the possibilities of the domestic refrigerator as a load builder and its value as a central-station load.

Farley Osgood, consulting engineer and Past-President of the Institute, was the last speaker on Friday afternoon. He took as his subject *Engineering and Humanity*, telling of the responsibilities and opportunities for service by the engineer in solving city, state and national problems.

On Friday at noon a luncheon was given by Vice-president Pierce to the Branch Counselors of the Middle Eastern District and a few other guests. A committee on Student Activities of the District was organized consisting of all the Branch Counselors within the District and the Vice-President and Secretary of the District. Prof. H. B. Dates of the Case School of Applied Science Branch was elected Chairman.

Visit to Nela Park

On Friday evening a trip was made to Nela Park, the laboratory and plant of the National Lamp Works of the General Electric Company. At the Park short addresses were made by R. W. Shenton of the National Lamp Works, on *Nela Park, Its Organization and Objectives*, and by Ward Harrison, National Lamp Works, on *Recent Developments in Illumination*. Following these addresses there were demonstrations of illumination for industry, automobiles and the home, and then visits were made to the laboratories and historical museums.

A number of other trips were made on Saturday morning by small groups and individuals to various places of engineering and civic interest.

The able general committee which planned this convention was as follows: A. G. Pierce, Vice-President of Middle Eastern District; A. M. MacCutcheon, General Chairman; C. S. Ripley, Secretary; L. D. Bale, Transportation; H. B. Dates, Program; C. L. Downs, Reception; H. L. Grant, Publicity; G. A. Kositzky, Finance; A. M. Lloyd, Registration; E. H. Martindale, Attendance; C. N. Rakestraw, Dinner, and I. H. Van Horn, Trips. A large number of committee members worked faithfully and effectively under these men, resulting in a most successful and enjoyable meeting to all who attended.

Regional Meeting of Great Lakes District at Madison May 6-7

A two-day Regional Meeting will be held by the Great Lakes District of the Institute in Madison, Wisconsin, on May 6 and 7, with headquarters at the Hotel Loraine. An interesting program has been arranged featuring the following topics:

Rural Electrification
Developments in High-Tension Underground Cables
Cooperative Research Relations Between the Colleges and the Industries
Performance of Radio Receiving Circuits.

On Thursday evening, May 6th, a dinner will be given at which President Glenn Frank of the University of Wisconsin will give the address.

A luncheon meeting for the Counselors of the Student Branches of the District has been scheduled for Thursday noon. Thursday afternoon will be devoted to inspection trips to points of interest such as the hydroelectric plant at Prairie du Sac, the Forest Products Laboratory, the University, the Capitol, and the industries of Madison. Several excellent golf courses will be open to members attending the meeting.

The meeting and program committee consists of the following: Chairman, Edward Bennett; J. B. Bailey, A. G. Dewars, H. R. Huntley, L. E. A. Kelso, Carl Lee and R. G. Walter.

The chairmen of the various local committees are as follows: C. M. Jansky, Publicity and Attendance; John R. Price, Hotel and Dinner; L. J. Peters, Registration and Reception; R. G. Walter, Finance; C. B. Hayden, Entertainment and Trips.

Madison is easily reached by automobile by any one of several routes. Detailed information concerning condition of roads may be obtained by addressing Mr. J. C. Bitterman, Madison Association of Commerce, Madison, Wisconsin.

PROGRAM OF MADISON MEETING

THURSDAY MORNING

9:00 A. M. Registration.
9:45 A. M. Technical Session: R. G. Walter, Chairman.

Rural Electrification, by Grover C. Neff, Wisconsin River Power Company.

Important Features of a Successful Plan for Rural Electrification, by George G. Post, Milwaukee Electric Railway & Light Company.

These papers will be discussed by R. A. Stewart, University of Minnesota; Eugene Holcomb, Consumers Power Company; C. B. Hayden, Railroad Commission of Wisconsin; R. A. Duffee, University of Wisconsin; and E. H. Lehman, University of Illinois.

THURSDAY NOON, 12:30 P. M.

Luncheon meeting of Branch Counselors.

THURSDAY AFTERNOON

Inspection Trips and Golf.

THURSDAY EVENING

Regional dinner at the Hotel Loraine. Address by President Glenn Frank, of the University of Wisconsin.

FRIDAY MORNING, 9:00 A. M.

Technical Session: R. F. Schuchardt, Chairman.

The Quality Rating of High-Tension Cable, by D. W. Roper and Herman Halperin, Commonwealth Edison Co.

Tests on High-Tension Cable, by F. M. Farmer, Electrical Testing Laboratories.

The Effect of Internal Vacua in High-Voltage Cable, by W. A. Del Mar and C. F. Hanson, Habirshaw Electric Cable Co.

Some Interconnected-System Operating Problems, by F. G. Boyce, Consumers Power Co.

FRIDAY AFTERNOON, 2:00 P. M.

Technical Session: Arthur Simon, Chairman.

Cooperation Between the Colleges and the Industries in Research

Paper or addresses by:
Wm. E. Wickenden, Society for the Promotion of Engineering Education.
Dean A. A. Potter, Purdue University.
Benjamin F. Bailey, University of Michigan.
Dean Milo S. Ketchum, University of Illinois.
Edward Bennett, University of Wisconson.

Behavior of Radio Receiving Systems to Signals and to Interference, by L. J. Peters, University of Wisconsin.

SATURDAY MORNING

Inspection trips: Cars and guides will be provided for trips to points of interest for those who are unable to take advantage of the trips arranged for Thursday afternoon.

Niagara Regional Meeting May, 26-28

High-grade technical sessions and some unusual entertainment features mark the program of the Regional Meeting which will be held at Niagara Falls, N. Y., May 26-28, under the direction of the Northeastern District of the Institute. The new Niagara Hotel will be headquarters for the meeting.

The technical subjects to be presented include measurement of power factor in dielectrics, transmission, tests of hydroelectric units, speed measurements, rectifiers, transformer design, radio-wave propagation, armature reactance, magnetic-flux measurements, supervisory control, fire protection for generators, etc. A list of the proposed papers is shown in the accompanying tentative program.

A very attractive entertainment program has been arranged, including a trip on Lake Ontario, a scenic and inspection trip in the Gorge, a convention dinner, two interesting lectures and a special illumination of the Falls. Special entertainment features are being planned also for the ladies.

The steamer trip on Lake Ontario is arranged for Wednesday evening, May 26. The party will travel by the Gorge route to Lewiston, where the lake steamer will be boarded. Then a moonlight ride on the lake with dancing for those who desire it will afford enjoyment until a late hour.

A trip down the Niagara Gorge will be made on Thursday afternoon; those taking this trip will see the famous rapids and the whirlpool from both sides of the ravine. Stops will be made at the many points of scenic interest and also at the plants of the Niagara Falls Power Company and of the Hydro-Electric Power Commission of Ontario.

On Thursday evening the convention dinner will be held in the Niagara Hotel and a number of the Institute officers will speak briefly.

Following the dinner there will be given with demonstrations a most interesting lecture on the subject "Modern Reproduction of Sound."

SPECIAL ILLUMINATION OF THE FALLS

A spectacle of great beauty is planned for Thursday night when the Niagara Falls will be specially illuminated with many changing and moving colors. There will be features of this illumination never before shown.

A piano recital together with one of his unique and entertaining interpretations of the music will be given by Vladimir Karapetoff on the evening of Friday, May 28. The many Institute members who have heard Professor Karapetoff in other recitals know that this will be a delightful event.

If possible, the first showing of the new film of the Niagara Falls Power Company will be made on Friday evening in connection with a lecture on the power development of the Niagara Falls. This film will illustrate the possible future power and scenic development of the Falls.

Application has been made for reduced railroad rates under the

certificate plan. If the rates are granted it is hoped that everyone who travels by rail will get a certificate when purchasing his ticket whether or not he intends to make use of the reduced fare. By getting a certificate he will help make up the 250 certificates necessary to obtain the reduction for those who wish to take advantage of it.

The general arrangements for this meeting are being made under the direction of the Coordinating Committee of the Northeastern District of the A. I. E. E. which is as follows: H. B. Smith, Vice-President in Northeastern District; A. C. Stevens, Secretary; J. R. Craighead, E. D. Dickinson, J. A. Johnson, A. E. Soderholm and A. W. Underhill, Jr. The local arrangements are in charge of a committee of which J. A. Johnson is chairman.

TENTATIVE PROGRAM OF NIAGARA FALLS REGIONAL MEETING MAY 26-28, 1926.

WEDNESDAY MORNING AND AFTERNOON, MAY 26

Technical Session—Symposium on Dielectrics and Power-Factor Measurements.

The Power Factor of Dielectrics and Insulation, by J. B. Whitehead, Johns Hopkins University.

The Mechanism of Breakdown of Dielectrics, by P. L. Hoover, Harvard University.

Standards for Measuring Power Factor of Dielectrics, by H. L. Curtis, Electrical Testing Laboratories.

The Significance of Errors in Dielectric-Loss Measurements, by C. F. Hanson, Habirshaw Electric Cable Co.

Use of Dynamometer Wattmeter for Measuring Dielectric Power Loss, E. S. Lee, General Electric Co.

Commercial Dielectric-Loss Measurements, by R. E. Marbury, Westinghouse Elec. & Mfg. Co.

Three Methods of Measuring Dielectric Power Loss and Power Factor, by C. D. Doyle and E. H. Salter, Electrical Testing Laboratories.

Compensation for Errors of the Quadrant Electrometer, by D. M. Simons, Standard Underground Cable Co.

The Dielectric-Loss-Measurement Problem, by B. W. St. Clair, General Electric Co.

Zero Method of Measuring Power with a Quadrant Electrometer, by W. B. Kouwenhoven and P. L. Betz, Johns Hopkins University.

WEDNESDAY AFTERNOON AND EVENING

Special cars will leave for Lewiston following the afternoon technical session, for the steamer trip on Lake Ontario. Executive committee and other committee meetings will be held on the boat.

THURSDAY MORNING

Technical Session

Rectifiers and Their Auxiliary Devices, by O. K. Marti, Cornell University.

Rectifier Voltage Control, by D. C. Prince, General Electric Co.

Radio-Wave Propagation, by E. F. W. Alexanderson, General Electric Co.

Circulation of Harmonics in Transformer Circuits, by T. C. Lennox, General Electric Co.

A Flux-Voltmeter for Magnetic Tests, by G. Camilli, General Electric Co.

THURSDAY AFTERNOON

Scenic Trip in the Gorge and Inspections of Power Plants

THURSDAY, 6:30 P. M.

Convention Dinner

THURSDAY EVENING

After the dinner will come the lecture "Modern Reproduction of Sound" and following the lecture the special illumination of Niagara Falls.

FRIDAY MORNING

Technical Session

Variable Armature Leakage Reactance, by V. Karapetoff, Cornell University.

Fire Protection for A. C. Generators, by J. A. Johnson, Niagara Falls Power Co. and E. J. Burnham, General Electric Co.

Automatic and Supervisory Control of Hydroelectric Generating Stations, by F. V. Smith, Westinghouse Elec. & Mfg. Co.

Tests on Niagara Falls Hydroelectric Units, by J. A. Johnson, Niagara Falls Power Co.

Speed Measurements of Rotating Machines, by P. A. Borden, F. K. Dalton and H. S. Baker, all of the Hydro-Electric Power Commission of Ontario.

FRIDAY AFTERNOON

Technical Session on Power Transmission

Interconnection and Superpower, by S. Q. Hayes, Westinghouse Elec. & Mfg. Co.

European Transmission Practises, by G. F. Chellis, Whitehall Securities Corp.

Lightning and Other Experience on 132-Kv. Transmission Lines, by M. L. Sindeband and P. S. Sporn, American Gas and Electric Co.

Notes on the Vibration of Transmission-Line Conductors, by Theodore Varney, Aluminum Co. of America.

Transmission-Line Sag Calculations, by H. B. Dwight, Massachusetts Institute of Technology.

FRIDAY EVENING

Piano Recital, Vladimir Karapetoff

Lecture on the *Power Development of the Niagara Falls*, Illustrated with motion pictures.

April 13th Meeting of I. E. C. to be Addressed by Prominent European Engineers

On the evening of the first day of the coming plenary session of the International Electrotechnical Commission which is to be held in New York, April 13th to 22nd, a general meeting is scheduled for the Auditorium, Engineering Societies Bldg., 33 West 39th St., New York, which should prove of great interest to all engineers. The program for the evening calls for the opening of the meeting by Dr. C. O. Mailloux, Honorary President of the I. E. C. He will then introduce Dr. Clayton H. Sharp, President of the United States Committee. Dr. Sharp will turn the meeting over to John W. Lieb, Chairman of the Reception Committee who will call upon Professor Elihu Thomson to make the address of welcome to the foreign delegates. There will be a brief response by Colonel R. E. Crompton, C. B., Honorary Secretary of the Commission. Brief address will be given by representatives of France, Poland, Germany, Scandinavia and Japan. The principal address of the evening will be made by Guido Semenza of Milan, Italy, President of the International Electrotechnical Commission on "The Accomplishments and Aims of the International Electrotechnical Commission."

An outline of the program for the entire week was given in the March JOURNAL, page 297.

Doctor R. A. Millikan to Speak on "High-Frequency Cosmic Rays"

The members of the New York Section of the A. I. E. E. and the New York Electrical Society are to have the wonderful opportunity of again listening to an address by Dr. R. A. Millikan, Director, Norman Bridge Laboratory, California Institute of Technology. Dr. Millikan will describe his recent work in

the detection of "High-Frequency Cosmic Rays," carried on at Lake Muir at the summit of Mt. Whitney and Arrowhead Lake in the San Bernardino mountains, also on Pike's Peak in which he determined that these rays, at first called "penetrating radiation" of the atmosphere, come definitely from above. The shortest wave length determined corresponds to a frequency 10,000,000 times higher than that of visible light and that the computed frequencies correspond closely to the energy involved in the simple capture of an electron by a positive nucleus.

Dr. Millikan, as those who have had the pleasure of listening to his previous talks know, can present an intricate and difficult subject in a way which all can understand. He has been the recipient of, among numerous other awards, the Edison Medal in 1922 and the Nobel Prize of the Swedish Academy in 1923.

The meeting will be held in the Auditorium, Engineering Societies Building, 33 West 39th Street, New York, at 8 p. m., on Saturday evening, April 10, 1926.

New York Section to Hold Student Convention

The New York Section will hold its first Student Convention on Friday, April 23, 1926. The plans for this convention have been under way for some time, through conferences of N. Y. Section officers and a committee representing the student body of the eight colleges within the New York Section territory, as follows: College City of New York, Columbia, Cooper Union, New York University, Newark College of Engineering, Polytechnic Institute of Brooklyn, Rutgers University and Stevens Institute of Technology.

The morning of April 23rd will be devoted to inspection trips to the G. E. Lamp Works at Harrison, N. J.; the Bell Laboratories, and the I. R. T. repair shops. An afternoon session in Room 1, Fifth Floor, Engineering Societies Building, 33 West 39th St., New York, will start at 2:30 p. m. with one student speaker from each of the eight colleges. President Pupin will give a short address. A get-to-gether supper will follow at the Fraternity Club. Tickets to be sold at $1.50 each.

The evening program is being arranged by the New York Section officers and is to be of particular interest to students. The session will be held in the Auditorium at 8:15 p. m. Definite announcement of speakers will be made later.

Future Section Meetings

Baltimore

Talk by a Member of the Local Section. Engineers' Club. April 16, 8:15 P. M.

Induction Interference, by H. S. Phelps. Engineers' Club. May 21, 8:15 P. M.

Spring Meeting of the American Society of Civil Engineers

On April 14th, at Kansas City, Mo., the American Society of Civil Engineers will open the program of its Spring Meeting with the subject on the Relation of the Railroads to Modern Highway and Urban Traffic. This will be followed on Wednesday by an important session on the question of Urban and Interurban Busses, and on Thursday, April 15th, the Technical Divisions will hold sessions in their various fields. Programs have been arranged by the City Planning, Construction and Sanitary Engineering Divisions, with the presentation of two important papers and discussion thereon. In addition to the comprehensive technical program, a number of delightful social events and sightseeing and inspection trips are planned. The dinner dance will be held in the roof garden and ball room of the Kansas City Athletic Club. The Official program is now available to any wishing to review a copy.

Important Meeting of New England Engineers

With all New England engineering interests joining heartily in the support and promotion of its success, the program of the Providence Sections of the American Society of Mechanical Engineers is being completed for a gigantic gathering of professional interests May 3-6, 1926. The opening session of the meeting will have for its subject Industrial Education, followed, Tuesday morning, by a session on Small Parts Manufacture, Industrial Power and Wood Industries; Wednesday morning's sessions will be devoted to Cold-working of Metals, Central Power Stations Problems and Textiles. Some features for which arrangements have already been consummated include visits to the Narraganset Electric Lighting Company, Brown & Sharpe Mfg. Co., the Providence Gas Company and selected textile and rubber plants. Entertainments will be a reception Monday evening, a men's luncheon Tuesday, a Rhode Island Clam Bake Tuesday evening and an informal dinner Wednesday. On Thursday, the party will visit the Newport Torpedo Station and will be afforded the unusual opportunity of seeing the torpedoes launched and visiting will also include an inspection of the shops training station, the old battleship, Constellation and Newport itself.

Student Convention at Swarthmore

The second annual student convention of the Philadelphia Section of the A. I. E. E., held at Swarthmore College on Monday, March 8th, was an eminently successful continuation of last year's pioneer event. Two hundred and twenty-nine students of electrical engineering, from Delaware, Drexel, Haverford, Lafayette, Lehigh, Pennsylvania, Princetown, Swarthmore and Villa Nova, met for a convention run by themselves on lines quite like those of regular A. I. E. E.

After inspection of the laboratories, the morning sessions were opened by an address of welcome by Dr. Lewis Fussell, Professor of Electrical Engineering, who immediately turned the session over to E. D. Gailey, '26, Chairman of the Swarthmore College Branch. A varied program of four papers drew forth a lively discussion and absorbed the attention of all. This morning session comprised the following papers:

Recent Developments in Power Plants, Herbert Estrade, University of Pennsylvania, 1926

Electricity in Motion-Picture Theatres, F. G. Kear, Lehigh University, 1926

Electron Theory as Applied to the Discharge Tube, Irvin A. Travis, Drexel Institute, 1926

Some Recent Developments in the Incandescent-Lamp Industry, Homer A. Blake, University of Delaware, 1926.

Luncheon, as guests of Swarthmore, was followed by inspections

of buildings and campus, and at 2:30 four parties left by auto for trips of inspection to the following plants:

Chester Waterside Plant of the Delaware County Electric Co., Chester, Pa.

South Philadelphia Works of the Westinghouse Electric and Manufacturing Company, Lester, Pa.

Pine Ridge Automatic Substation, Philadelphia and West Chester Traction Co., Pine Ridge, Pa.

Baldwin Locomotive Works, Eddystone, Pa.

The laboratories were open again from 6 to 7, at which time students and many men of the Philadelphia section learned how complete an equipment is available in this small college. The dinner, of which 119 partook, and the evening session attended by 180, constituted the regular March meeting of the Philadelphia Section, with C. D. Fawcett, past-chairman, in charge. He introduced National Secretary F. L. Hutchinson, who spoke in a most illuminating way of "Institute Activities," pointing out the numerous ways in which the student and the Institute can be mutually beneficial.

Farley Osgood, consulting engineer, and Past-President of the A. I. E. E., spoke in his forceful way on "College—Then What?" bringing clearly to the most casual student the idea that his place in the world is what *he* will make it, and that a technical education is the best possible preparation for any kind of life. A number of interesting "stunts" were then presented, dancing, music, etc., and the day was brought to a close with a few remarks by Dr. Fussell. He stressed the fact that the success of the convention type of meeting, in which the Philadelphia Section is the pioneer, is now established and should insure its continuance as an annual event.

The Student Branch Activities Committee, consisting of Professor Morland King of Lafayette, Professor L. H. Rittenhouse of Haverford, Professor Malcolm Maclaren of Princeton, Professor J. G. Brainerd of University of Pennsylvania, Professor Dean Tanzer of Drexel Institute, and Professor L. Fussell of Swarthmore, Chairman, and the local committees under Mr. Gailey deserve great credit for perfecting the details of an extremely well thought out and smooth running convention.

Adoption of Metric System Discussed

The House Committee on Coinage, Weights and Measures opened hearings in Washington, March 4th, on a bill which proposes to make the metric system effective in this country after January 1935. While opposition as well as approval of the bill was expressed by representative men, it is generally contended that the ultimate good to be derived from the adoption of a universal unit of measure is obvious, in view of which the earlier it is put into effect the sooner will the whole situation be simplified. As Major Fred J. Miller, past-president of the A. S. M. E. expressed it, "A gram of prevention is worth a kilogram of cure." Some of those opposing the bill were Luther D. Burlingame, chairman of the A. S. M. E. Committee on Standardization and Unification of Screw Threads, other representatives of the A. S. M. E. on the National Screw Threads Commission and C. C. Stutz, Secretary of the Institute of Weights and Measures, while the passage of the bill was supported by S. W. Stratton, Gano Dunn, Thomas A. Edison, General Pershing, Samuel Vauclain, and others of representative prominence.

Doctor Whitehead Chosen Exchange Professor to Lecture in France

Doctor J. B. Whitehead, Dean of Engineering of Johns Hopkins University, and a Director of the A. I. E. E., has been selected by seven American universities as their international exchange professor to France. His appointment was made under an arrangement among Harvard, Yale, Columbia, Cornell, University of Pennsylvania, Massachusetts Institute of Technology, Johns Hopkins and the French Government to establish an exchange professorship of engineering and applied science for the two countries.

The course of lectures to be given by Doctor Whitehead at the French universities which he will visit during the first half of 1927, will deal with the subject of "Insulation and the Dielectric Theory." Doctor Whitehead is known throughout the world for his research on the problems of insulation, having delivered many papers on this subject before the A. I. E. E. His research on high-voltage insulation received recognition in Europe last year when he was awarded a triennial prize of the George Montefiore Foundation of Belgium for his series of papers on "Gaseous Insulation in Built-up Insulation." He also received this prize in 1922 for another paper on "The Corona Voltmeter and the Electric Strength of Air." Among other honors for papers in the same general field was his recent receipt of the Longstreth Medal of the Franklin Institute.

This professorship was established at the close of the war for the purpose of exchanging knowledge between France and America through interchanging professors of outstanding ability. Dr. A. E. Kennelly, Professor of Electrical Engineering, Harvard University, Past-President of the Institute, was the first American selected for this exchange (1921-22). During the last four years three other American scientists have had this honor, namely: Dr. E. M. Chamot, professor of Sanitary Chemistry, Cornell University; Dr. D. W. Johnson, Professor of Physiography, Columbia University, and Dr. John Frazer, Dean of the Towne School of Engineering, University of Pennsylvania. In the same period Prof. J. Cavallier, Recteur, University of Lyons; Prof. Emmanuel de Margerie, Geologist, University of Strasbourg, and Prof. Pierre Lemaire, Professor of Mechanical Enginering, University of Lyons, have come from France to the United States.

John Ericsson Medal Established

A gold medal to be known as "The John Ericsson Medal" and to be awarded to Americans of Swedish birth or descent, or to Swedish citizens, as a recognition of distinguished accomplishments in science and engineering, was established in January 1926 by the American Society of Swedish Engineers. This medal which was established in honor of the great engineer and scientist, Ericsson, will be awarded not oftener than once in two years on a recommendation of a medal committee comprising four members each of the Swedish Academy of Engineering Science and the American Society of Swedish Engineers.

The first award will be made at the time of unveiling the John Ericsson monument in Washington, D. C., in May. The American Society of Swedish Engineers, which has headquarters in Brooklyn, N. Y., was founded in 1888 and has a membership of approximately 500.

Medal for Radio Amateurs

A medal for those who serve humanity through radio by bringing aid in time of peril has been offered by the magazine *Popular Radio*. The awards will be made to non-professionals through whose efficient action radio is utilized to alleviate suffering or save life within the territory and waters of the United States.

Those who qualify for this recognition should be brought to the attention of the Committee of Awards, Popular Radio Medal for Conspicuous Service, 627 West 43rd Street, New York.

A World Language For Electricity

Plans to formulate a universal language for electricity will come before a ten-day plenary convention of the International Electrotechnical Commission to be held in New York beginning April 13th, as announced by Doctor Clayton Halsey Sharp, president of the United States Committee of the Commission. National committees of the Commission in America, Great

Britain and countries of the Continent have been developing studies in this field and their reports will be submitted at this meeting, the first to be held in this country. Radio expansion, it is declared, has increased the demand for common terms and symbols, and steps have already been taken as a part of the general program for worlds standards, to meet this situation in an electrical language. An international dictionary of electrical terms is also one of the aims of the Commission.

A. I. E. E. Year Book

The 1926 issue of the Year Book goes to press about April 1st and copies will be available for distribution shortly thereafter.

The book contains an alphabetical and geographical catalog of the membership, revised to January 1, 1924; also the constitution, by-laws, lists of officers and committees, and much additional information relating to the activities of the Institute.

New York Section Nominations for 1926-27

The Nominating Committee of the New York Section has named the following ticket for officers of the New York Section for the year 1926-27: Chairman, E. B. Meyer, Public Service Electric Co.; Secretary-Treasurer, O. B. Blackwell, American Telephone and Telegraph Co.; Executive Committee, J. B. Bassett, General Electric Co. and C. R. Jones, Westinghouse Elec. & Mfg. Co. Mr. H. A. Kidder, the present chairman, automatically becomes Junior Past Chairman on August 1st and makes the fifth member of the Executive Committee. The ballots for the above ticket are now before the Section membership and final results will be announced at the April 23rd meeting of the Section.

PERSONAL MENTION

Frederick W. Walker has closed his Chicago office, and, effective March 1st, 1926, has been appointed vice-president of the Northwestern Mutual Life Insurance Company, Milwaukee, Wis.

Joseph Rogoff, who was industrial engineer for the Salt's Textile Company, Inc., Bridgeport, Conn., has been appointed superintendent of the Gaynor Electric Company, Inc., of that city.

Bertram Wardle, who was chief draftsman for the English Electric Co. of Canada, Ltd., has recently identified himself with the Canadian General Electric Co., Peterboro, Ontario, Canada.

W. J. Moulton-Redwood, of the engineering staff of the Canadian National Carbon Company and the Prest-O-Lite Company of Canada, has resigned from these interests and gone to Auckland, N. Z., for Commercial engineering work.

J. Maldonado, formerly electrical engineer for the Brooklyn Edison Company, has signed a contract with the Worthington Pump and Machinery Corporation of New York and will assume the managership of their Barcelona Offices, Compania de Bombas Worthington, Plaza Universidad, 2, Barcelona, Spain.

George L. DeMott, after seven years' service as examiner in the United States Patent Office in charge of the Electrical Measuring Instrument art and having completed a four years' course in law in addition to his previous technical training, has become associated with the Union Switch and Signal Company of Swissvale, Pennsylvania, as assistant patent counsel.

S. R. Williams, formerly special representative of the Westinghouse Electric and Manufacturing Company, with headquarters at South Bend, Indiana, has been appointed their street lighting engineer at Boston. Mr. Williams was also at one time connected with the Philadelphia office of the company, assisting in the sale of street lighting equipment. He is a graduate of the Westinghouse student sales and engineering course.

H. J. E. Reid, an Associate of the Institute, on January 1, 1926, was appointed Engineer-in-charge of the Langley Memorial Aeronautical Laboratory of the National Advisory Committee for Aeronautics at Langley Field, Virginia. Mr. Reid received his engineering education at Worcester Polytechnic Institute and for the past five years has been chief of the Instrument Section of the laboratory of which he is now in charge. He has the honor of being the youngest man to receive appointment to such an important position in aeronautical research.

Obituary

Albert Cavallo Jewett, who joined the Institute in 1906 and the following year was elected to Life Membership, died on February 3d, 1926, at Papeete, on the Island of Tahiti. Mr. Jewett was born in Henderson County, Kentucky, December 20th, 1869, and for four years after he was of eligible age, studied under a private tutor. His technical education was acquired while he was in the employ of the General Electric Company. From 1890 to 1892 he was with the Thomson Houston Electric Company, Colorado and California, after which he spent a year with the General Electric Company. In December of the year 1903 he went to Messrs. John Taylor & Sons, London, England and from then, the first of December 1905, entered the employ of H H. The Maharajah, Jammu and Kashmir, as electrical advisor to the Government of India. The installation of the original Redlands transmission line was done by Mr. Jewett in 1893, and this was followed by the installation of many other equally important systems in California districts up to the year 1900.

Addresses Wanted

A list of names of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

1.—William E. Ames, Detroit Edison Co., Detroit, Mich.
2.—H. R. Bailey, Electric Bldg., Portland, Ore.
3.—I. Bergenstrahle, 425 West 114th St., New York, N. Y.
4.—Hubert L. Clary, 782 West 24th St., Milwaukee, Wis.
5.—J. E. Contesti, 350 W. 58th St., New York, N. Y.
6.—Ralph Elsman, 120 Broadway, New York, N. Y.

26.—John D. Walker, 2686 Woodstock Ave., Swissvale, Pa.
27.—A. R. Williamson, 561 Delaware Ave., Norwood, Pa.
28.—I. H. Worley, 2124 E. St., Lincoln, Nebr.
29.—M. L. Younger, 1814 Diamond St., Philadelphia, Pa.

Extracts from Annual Report for 1925

The year has been one of steady operation, unmarked by unusual occurrences. The number of users of the Library was practically the same as in 1924, amounting to about 70% of the membership of the Founder Societies.

The budget adopted for 1925 called for the expenditure of $44,200 for the general maintenance of the Library. The actual expenses were $41,176.89. But while the cost has been kept within the budget, this should not be taken as an indication that more money should not be appropriated for Library work. To accomplish this result, it has been necessary to decline to undertake many activities that are desired by members and that would be permanent improvements.

There is, for example, a distinct need for more ample indexing of the output of current periodical literature. This has reached the point where few engineers can afford the time necessary to examine it; as a consequence they must rely upon bibliographies and abstracts to guide them. Here there is a wide field for developments that would be useful to every member.

There have also been opportunities during the year to purchase private libraries of unusual importance, which could not be accepted. Similar opportunities will undoubtedly again arise from time to time, and it is highly desirable that your Board be in a position to take advantage of them.

Your Board constantly regrets its inability to develop the work in these and other ways that are suggested from time to time. It realizes, however, that its first duty is to restrict the cost of its operations to the sums set apart for the purpose and so confines the work to what can be done with the funds available.

The equipment of the Library is generally in satisfactory condition.

During the year the lighting of the reading room was investigated and found below the best practise of the day. Methods for its improvement are now being studied.

The accessions during 1925 and the book stock on 31 December, 1925, are as follows:

	Vols.	Pamphlets	Maps	Searches	Total
On hand Jan. 1, 1925....	100,111	4,001	1,641	3,991	109,744

Book Reviews

THE RELAY HANDBOOK.

Prepared by the Relay Subcommittee, Electrical Apparatus Committee, and Technical National Section of the National Electric Light Association in collaboration with the Relay Subcommittee and Protective Devices Committee of the American Institute of Electrical Engineers, a volume to be known as the Relay Handbook is now available through the offices of the National Electric Light Association, Engineering Societies Building, New York.

The first point of the book is given over to many valuable tables of carefully computed engineering data, followed by text descriptive of relays and their uses, tests and maintenance and concluded with information of calculations applying to the subject. There is also an extensive bibliography, arranged sectionally and in chronological order under the several important heads. The possibilities of protecting electrical systems from faults involving the energy within the system have made such marked progress within recent years has made the publishing of the present handbook a great asset to the profession. The increasing size and extensive interconnection of the systems is also safeguarded in this publication of theory as well as practise. It reduces a volume of data to usuable form, well proportioned with regard to scope, authority and comprehensiveness.

POPULAR RESEARCH NARRATIVES.

Volume II of "Popular Research Narratives" has been published through the Engineering Foundation, 29 West 39th Street, New York. From the preface "Mankind must progress or regress—let us go forward seeking the truth and using it for the betterment of all mankind" is best descriptive of the effort and purpose of the work, which is a collection of fifty brief stories of research, invention and discovery by such eminent scientists as Doctor

M. I. Pupin, H. C. Hayes, Major General George O. Squier, Chief Signal Corp of the U. S. Army, Doctor Arthur E. Kennelly, Member of the National Academy of Sciences; Chevalier Legion d'Honneur, William G. Houskeeper, Research Laboratories of the American Telephone and Telegraph Company, Sir Ernest Rutherford, President of the British Association for the Advancement of Science, Messrs. Arnold and Elmen of the Research Laboratories of the American Telephone and Telegraph Company and the Western Electric Co., Inc., and many others who have contributed greatly to the research and application of science. The book is a convenient size, 5 x 7, contains 160 pages and sells for $1.00.

THE FUNDAMENTAL CONCEPTS OF PHYSICS in the Light of Modern Discovery. Williams & Wilkins, Baltimore, Md.

This work, by Paul R. Heyl, Ph. D., Physicist, Bureau of Standards, Washington, contains three lectures: The Eighteenth Century: The Century of Materialism; The Nineteenth Century; The Century of Correlation; and The Twentieth Century; The Century of Hope. 112 pages. Size of Volume 5 x 7. Price $2.00.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES (FEBRUARY 1-18, 1926)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

ANNUAIRE POUR L'AN 1926.

France. Bureau des Longitudes. Paris, Gauthier-Villars, 1926. 665 + 337 pp., 6 x 4 in., paper. 8 fr.

The 1926 edition of this well-known reference book contains the usual collection of data on the calendar, the earth, astronomy, weights and measures and physical and chemical constants, and is a valuable compilation of information frequently wanted by physicist, chemists, astronomers, etc. In addition it contains a lengthy account of the International Research Council and the Astronomical Union, by B. Baillaud, and an article by G. Pervier, entitled the Geodesic Reasons of Terrestrial Isostasy.

DAS DEUTSCHE PATENTRECHT.

By F. Damme and R. Lutter. 3rd edition. Berlin, Otto Liebmann, 1925. 692 pp., 9 x 6 in., paper. 28.-mk.

A new edition of a standard text on German patent law and practise, prepared by a former and the present director of the Patent Office. The discussion is comprehensive and practical as well as thoroughly up to date.

DIESEL MASCHINEN. Sonderheft, V. D. I. Zeitschrift 1925. 97 pp., illus., diagrs., plates.

ENTGASEN UND VERGASEN. Sonderheft, V. D. I. Zeitschrift, Bd. 69. 116 pp., illus., tables.

TECHNISCHE MECHANIK. Erganzungsheft, V. D. I. Zeitschrift, Bd. 69. 84 pp., illus., diagrs.

Berlin, V. D. I., Verlag, 1925-26. 3 vols., 12 x 8 in., paper. Prices not quoted.

These three publications contain collections of important articles on their various subjects, selected from recent issues of the Zeitschrift des Vereines deutscher Ingenieure and reprinted in this form for convenient use. The volume on Diesel engines contains articles on the Diesel locomotive from the viewpoint of locomotive construction, Diesel engines and gearing for large oil locomotives, high speed Diesel engines for vessels, compressorless Diesel engines, etc.

The volume entitled "Entgasen und Vergasen" considers various problems of fuel preparation and utilization. Among these are coal dressing, gas distribution, the improvement of coking coal at the mine, dry cooling of coke, the distillation of low-grade fuels, the Lurgi distillation process, the mechanical influence of fuel in gas generators, and new knowledge in firing practice.

Among the papers on technical mechanics are a criticism of thermal engines, heat transfer from oil to water and loss of pressure in cooling apparatus, heat transmission and loss of pressure in pipe coils, parallel flow and turbulence in circular pipes, resistance to flow in pipes, errors in the measurement of the temperature of flowing gases, fine measuring tools for tension in machine parts, the solution of statically indeterminate systems by means of the Nupubest instrument.

ECLAIRAGE ELECTRIQUE.

By P. Maurer. Paris, Gauthier-Villars et Cie., 1925. 143 pp., diagrs., 10 x 6 in., paper. 20 fr.

A text-book on electric lighting which is confined to a brief presentation of fundamental theory and of its application in practice. The author first discusses general principles and photometry. He then studies the different types of incandescent and arc lamps, after which he takes up the layout of lighting for various types of buildings. The final section is devoted to the installation of interior lighting systems.

ELECTRIC RAILWAY ENGINEERING.

By C. Francis Harding and Dressel D. Ewing. 3rd edition. N. Y., McGraw-Hill Book Co., 1926. 489 pp., illus., diagrs., tables, 9 x 6 in., cloth. $5.00.

A textbook for students in technical schools who wish to specialize in electrical railway engineering, in which present theory and practice in the important branches of the subject are brought together in convenient form.

The new edition has been completely revised and enlarged. A new chapter on motor-bus transportation has been added. The chapter on "Power Station Location and Design" has been replaced by one entitled "Sources of Electrical Energy," which contains a recent, very complete contract for electrical energy.

ELEKTROMETALLURGIE.

By K. Arndt. Berlin u. Leipzig, Walter de Gruyter & Co., 1926. 124 pp., illus., 6 x 4 in., cloth. 1,50 mk.

A brief review of the subject written in easily understood language. After a short introductory account of electrochemical principles, the author describes the recovery of copper, the precious metals, zinc, lead, tin, iron, etc., from aqueous solutions. The production of aluminum, magnesium, sodium, etc., by the electrolysis of fused salts is then described. The final section discusses the electrothermal processes for producing iron and its alloys.

ELEMENTARY ELECTRICAL TECHNOLOGY FOR ENGINEERING STUDENTS.

By A. M. Parkinson. Lond., Oxford University Press, 1925. 179 pp., 8 x 5 in., cloth. $2.00. (Gift of Oxford University Press. American Branch).

Confined to the elementary technology of electric circuits and aimed to present the principles as simply as possible, this book is intended to furnish the fundamental theory required as a foundation for a three or four years' course in applied electricity.

ELEMENTS OF ALTERNATING CURRENTS AND ALTERNATING CURRENT APPARATUS.

By J. L. Beaver. N. Y., Longmans, Green & Co., 1926. 370 pp., illus., diagrs., 9 x 6 in., cloth. $4.00 (Gift of Author).

A textbook for beginners in the study of alternating currents. The first eight chapters give an elementary presentation of principles, while the remaining four study the commonest types of alternating-current apparatus. Questions and numerical problems are appended to each chapter. The book is planned for a course of sixty to ninety hours.

FESTSCHRIFT ANLASSLICH DES 100 JAHRIGEN BESTEHENS DER TECHNISCHEN HOCHSCHULE FRIDERICIANA ZU KARLSRUHE. Karlsruhe, C. F. Müller, 1925. 542 pp., illus., diagrs., tables, 10 x 7 in., ¾ cloth.

A handsome volume commemorating the centenary of the oldest technical college in Germany. It contains 38 papers by members of the faculty, dealing with various subjects—mathematical, economic, mechanical, electrical, chemical and physical. A history of the beginnings of technical education is included.

Among the papers of especial interest to engineers are: Simplification of arch calculations, Methods of colonizing, City planning and building as a province of engineering, The influence of repeated loads on the elasticity and strength of concrete and reinforced concreto, Band spring drives, Calculation of shearing stress produced by punching, Heat transmission to water in a tube, Experiments on the straightening of crooked rods, Safety and economy of electric power transmission.

GALVANIZING.

By Heinz Bablik. Lond., E. & F. N. Spon; N. Y., Spon & Chamberlain, 1926. 168 pp., illus., tables, 9 x 6 in., cloth. $5.00.

As the manager of a large Austrian galvanizing works, the author has carried out various scientific investigations on the subject, which are assembled in this book. His purpose is to explain, in the light of modern scientific conceptions, processes already known in outward form.

Opening with a discussion of rust and its prevention, succeeding chapters deal with the structure of galvanized coatings, pickling, fluxes, hot galvanizing, raw materials and waste products, electro-galvanizing, sherardizing, metal spraying, and the testing of products.

MODERN MAGNETICS.

By Felix Auerbach. N. Y., E. P. Dutton & Co., 1925. 306 pp., diagrs., 9 x 6 in., cloth. $6.00.

Professor Auerbach has attempted to give a picture of the present state of the theory of magnetism, complete enough for the needs of every one except the specialist within the limits of one small volume. He has succeeded admirably, having produced a book that will not only interest engineers and teachers, for whom it is primarily intended, but can also be read by any general reader in search of knowledge on the subject. The style is easy and fluent, mathematics is reduced to a minimum, and the text is illustrated by numerous figures. A valuable select bibliography is appended.

POPULAR RESEARCH NARRATIVES, vol. 2; collected by the Engineering Foundation. Baltimore, Md., Williams & Wilkins Co., 1926. 174 pp., ports., 8 x 5 in., cloth. $1.00. (Gift of the Engineering Foundation).

The wide general interest that the first volume of "Research Narratives" excited has led the Engineering Foundation to publish a second volume. Here are fifty brief stories of useful inventions and discoveries, showing how the scientist and engineer proceed in advancing the welfare of mankind. The accounts are written in non-technical language, with unusual brevity, by men of experience in the subjects treated.

PRACTICAL PHOTO-MICROGRAPHY.

By J. E. Barnard and Frank V Welch. 2d edition. N. Y., Longmans, Green & Co., Lond., Edward Arnold & Co., 1925. 316 pp., illus., 9 x 6 in., cloth. $6.00.

A straightforward detailed account of the methods used in photographing microscopic objects, written by experienced workers. The book discusses the microscope, the optical equipment, sources of illumination, cameras, color screws, plates and photographic processes.

PRACTICAL RADIO, INCLUDING THE TESTIHG OF RADIO RECEIVING SETS.

By James A. Moyer and John F. Wostrel. 2d edition. N. Y., McGraw-Hill Book Co., 1926. 271 pp., illus., diagrs., 8 x 5 in., cloth. $1.75.

Attempts to present the fundamentals of the subject so simply and clearly that the average reader may understand and apply them. It also gives working drawings and specifications for the construction of a number of good receiving sets of various types. The new edition has been revised and a number of new subjects treated.

RAILROAD CONSTRUCTION.

By Walter Loring Webb. 8th edition. N. Y., John Wiley & Sons, 1926. 849 pp., illus., diagrs., tables, 7 x 4 in., fabrikoid. $5.00.

In addition to the revision of several chapters to conform with recent practice and the addition of several minor topics that have become important, special attention has been given in this edition to the relations of locomotive power to grade. A more exact method of computation has been introduced in the chapter on locomotive power, which has been rewritten and also used in the chapter on grade to show the effect of undulatory grades on power.

SCIENCE IN THE MODERN WORLD.

By Alfred North Whitehead. N. Y., Macmillan Co., 1925. (Lowell lecturers, 1925). 296 pp., 9 x 6 in., cloth. $3.00.

This volume, by the Professor of Philosophy in Harvard University, is a study of some aspects of Western culture during the past three centuries, in so far as it has been influenced by the development of science. Dr. Whitehead gives a thoughtful analysis of the reactions of science in forming that background of instinctive ideas which control the activities of successive generations. He points out the primary concepts upon which science seated itself during the period under consideration; calls attention to the recent breakdown of the seventeenth century settlement of physical principles and criticizes the current philosophy of scientists.

SIGNAL WIRING.

By Terrel Croft. N. Y., McGraw-Hill Book Co., 1926. 349 pp., illus., diagrs., 8 x 6 in., cloth. $3.00.

As signal wiring is principally a matter of knowledge of circuits, this book is chiefly a collection of circuit diagrams. Over 460 circuits are illustrated, including those usually wanted for wiring bells and annunciators, burglar alarms, hospital and hotel signals, time-clock signals, autocall signals, telephones, fire alarms, police calls, power station signals, water-flow and pressure alarms, elevator, mine, railroad and miscellaneous signals. A chapter is devoted to methods of wiring.

SUPERPOWER, ITS GENESIS AND FUTURE.

By William Spencer Murray. N. Y., McGraw-Hill Book Co., 1925. 237 pp., diagrs., maps, 9 x 6 in., cloth. $3.00.

As the Engineering Chairman of the United States Government Superpower Survey, Mr. Murray is already widely known as an authority on the question of the interconnection of power plants. The present book considers the question from a broader viewpoint than the government report and is intended for a wider audience. Stress is placed upon the social and economic advantages to be gained by "superpower" production and distribution, although the engineering problems are by no means neglected. Throughout, the main purpose is to present the principal features of the problem clearly and logically and to point out the benefits to be expected from "superpower."

TECHNICAL EDUCATION; Its Development and Aims.

By C. T. Millis. N. Y., Longmans, Green & Co.; Lond., Edward Arnold & Co., 1925. 183 pp., 8 x 5 in., ½ cloth. $2.25.

An account of the several movements which have led up to the present position of technical education in Great Britain, with some discussion of the problems that have arisen during its development. Starting with the Mechanics Institutes of 1824, the author traces the history of the various agencies, considers the principles of technical instruction and draws some conclusions.

THEORIE GENERALE SUR LES COURANTS ALTERNATIFS; pt. 2, Les Alternateurs.

By M. E. Piernet. Paris, Gauthier-Villars et Cie., 1926. 145 pp., diagrs., 10 x 6 in., paper. 30 fr.

A complete study, limited to fundamental practical ideas, of the technique of alternating-current machines and circuits.

The book supplements the author's previous work on continuous-currents and is intended for class-room use.

DIE TRANSFORMATOREN.

By Milan Vidmar. 2d edition. Berlin, Julius Springer, 1925. 751 pp., illus., diagrs., 9 x 6 in., cloth. 36 -r.m.

This, the most comprehensive of modern works on the transformer, is distinguished by its thorough grasp of the scientific principles involved and by its illustration of the application of these principles in actual design. The book will be useful to designers especially. The new edition has been carefully revised and considerable new matter has been added.

LES VEHICULES AUTOMOBILES.

By A. Boyer-Guillon. Paris, J.-B. Baillière et fils, 1926. 378 pp., illus., diagrs., 9 x 6 in., paper. 55 fr.

As head of the testing laboratory of the Conservatoire National des Arts et Métiers, the author of this book has made numerous tests of automobiles. In this work he has acquired a thorough knowledge of the functioning of these vehicles and their organs and has had an opportunity to compare different devices. The results of his experience are presented in this engineering study of the automobile, which presents a number of new points of view.

WELLENTELEGRAPHIE UND WELLENTELEPHONIE.

By M. G. Weinholz. Berlin u. Leipzig, Walter de Gruyter & Co., 1926. 132 pp., illus., diagrs., plates, 9 x 6 in., boards. 3,40 gm.

Intended as a textbook for use in technical and trade schools, where a practical course in radio communication is offered. The treatment is clear and non-mathematical, paying especial attention to the fundamental theory.

Past Section and Branch Meetings

SECTION MEETINGS

Boston

Testing of High-Tension Cable, by F. M. Farmer, Electrical Testing Laboratories. February 19. Attendance 265.

Chicago

The Problem of the Electrical Engineer from the Standpoint of a Physicist, by Max Mason, University of Chicago. Dinner Dance. February 6. Attendance 240.

The Financing of Public Utilities, by M. J. Insull, Middle West Utilities Co. Joint meeting with Electrical Section of the Western Societies of Engineers. March 1. Attendance 215.

Cincinnati

Electric Power Development in the Cincinnati District, by Monroe, Sargent and Lundy. Illustrated with slides. February 11. Attendance 174.

Graphic Measurements in Industry, by D. J. Angus, Esterline-Angus Company. Illustrated with slides. March 11. Attendance 50.

Connecticut

The Value of Patents, by Karl Fenning, Assistant to Attorney General, Department of Justice. February 16. Attendance 18.

Denver

Electrical Transmission of Pictures over Wires , by M. B. Long, Bell Telephone Laboratories, Inc. February 12. Attendance 55.

Detroit-Ann Arbor

D-C. Motor Maintenance, by L. Bogardus. Packard Motor Car Co.,

A.C. Motor Maintenance, by O.R. Candler, Dodge Brothers, Inc., and

Railway-Motor Maintenance, by A. C. Colby, Department of Street Railways. A motion picture, entitled "The Story of the Spark Plug," was shown. January 19. Attendance 125.

Long Telephone Cables, Their Possibilities and Problems, by F. B. Jewett, American Telephone and Telegraph Co. A motion picture showing the inauguration of the Ford Air Transportation Service was shown. February 16. Attendance 110.

Indianapolis-Lafayette

The Use of Graphic Records in Industry, by D. J. Angus, Esterline Angus Co., March 5. Attendance 32.

Ithaca

Hydro-Electric Power Development, by J. A. Johnson, The Niagara Falls Power Co. Illustrated with slides. January 15. Attendance 60.

Steam-Electric Power Development, by F. R. Ford, Philadelphia Electric Co. Illustrated with slides. February 19. Attendance 75.

Kansas City

The Manufacture of Rubber-Covered Wire, by R. J. Wiseman, Okonite Callender Cable Co. Illustrated with slides and moving pictures;

Maintenance of Electrical Equipment in Large Generating Stations, by C. B. Kelley, Kansas City Power and Light Co. February 8. Attendance 39.

Los Angeles

Forecasting Growth of Population an Aid to System Planning, by N B. Hinson, Southern California Edison Co.,

Application of Protective Equipment to Electric Transmission Systems, by E. R. Stauffacher, Southern California Edison Co., and

Steam Generation of Power and the Mercury Vapor Turbine, by F. G. Philo, Southern California Edison Co., March 2. Attendance 187.

Lynn

Social Meeting. March 1. Attendance 400.

Mexico

Technical Publications in the United States, by Mr. Cota. March 4. Attendance 18.

Milwaukee

The Work of the State Highway Department, by J. T. Donaghey, State Highway Engineer. January 20. Attendance 50.

The Vacuum Tube, by R. W. King, Editor of the Bell System Technical *Journal*. February 17. Attendance 500.

Minnesota

Dinner Dance. February 16. Attendance 60.

The Telephone System in Minneapolis, by the Commercial Department of the Northwestern Bell Telephone Co. A motion picture, entitled "The Audion," was shown. March 1. Attendance 100.

Niagara Frontier

Checking the Tuning Fork by Radio, by F. K. Dalton, Consulting Engineer. Illustrated with slides; and

The High-Voltage Air-Insulated Current Transformer, by L. C. Nicholson, Niagara Lockport and Ontario Power Co. Illustrated with slides. Mr. Dalton also gave an account of the destruction of a farm house due to lightning striking a radio aerial. February 19. Attendance 43.

Panama

Automatic Telephones, by J. K. Barrington, Automatic Electric Co. A short talk was also given by W. G. Ferris, Electric Bond and Share Co. February 10. Attendance 26.

Philadelphia

Supplying Electric Power to Downtown Philadelphia, by H. S. Davis and C. L. Gilkeson, Philadelphia Electric Co. Illustrated with slides. February 8. Attendance 180.

Pittsburgh

Voltage-Control Equipment for Interconnecting Power Systems, by J. S. Lennox, General Electric Co. Illustrated with slides. February 16. Attendance 160.

Pittsfield

Volcanoes and Earthquakes, by B. R. Baumgardt. Illustrated with slides. February 16. Attendance 700.

Lighting, by F. W. Peek, Jr., General Electric Co. Illustrated with slides and moving pictures. February 23. Attendance 75.

Ice by Wire—Electric Refrigeration, by W. P. White, General Electric Co. March 2. Attendance 175.

Portland

Social Meeting. February 10. Attendance 210.

Providence

Remote Supervisory Control, by R. J. Wensley, Westinghouse Elec. & Mfg. Co. Illustrated with slides. February 12. Attendance 20.

The Fynn-Weichsel Unity-Power-Factor Motor, by E. W. Goldschmidt, Wagner Electric Corp. March 9. Attendance 40.

Saskatchewan

Rural Electrification in Western Canada, by C. A. Clendening, Power Commission, Province of Manitoba. January 29. Attendance 42.

Turbine Development, by W. W. Johnson, General Electric Co., and

Measuring Output of A-C. Generators, by E. G. Fiske, General Electric Co. February 24. Attendance 40.

Schenectady

Aviation, by Major J. F. Curry, Illustrated with slides. January 22. Attendance 350.

Some Aspects of Corporate Industry's Relation to Society, by C. E. Eveleth, General Electric Co. February 12. Attendance 400.

Rambles in Asia, by B. A. Tozzer, Niles Bement Pond Co. Illustrated with slides. February 26. Attendance 300.

Seattle

Development in Illuminating Streets and Public Thoroughfares, by W. A. Turner, Department of Public Works, and

Transformer Design, by J. G. Corrin, Pittsburgh Transformer Co. Illustrated with slides. February 17. Attendance 52.

Sharon

The Klydonograph, by J. F. Peters, Westinghouse Elec. & Mfg. Co. A Smoker followed the meeting. March 2. Attendance 86.

Spokane

Automatic Substations, by C. E. Carey, Westinghouse Elec. & Mfg. Co. February 19. Attendance 40.

Springfield

The Quest of the Unknown by H. B Smith, Worcester Polytechnic Institute. Ladies Night. February 26. Attendance 100.

Toledo

Late Developments on A-C. Elevators, by E. B. Thurston, Haughton Elevator and Machine Co.;

My Experiences in the Early Days of the Electrical Industry, by Mr. Jeanin, Jeanin Motor Co.; and

Radio Sets, by E. B. Featherstone, Scott and Libbey High Schools. A talk was also given by Gilbert Southern on the functions of the Electric League, now being organized in Toledo to stimulate better wiring of residences. February 26. Attendance 34.

Toronto

International High-Tension Conference, Paris, 1925, by A. E. Davison, Hydro Electric Power Commission of Ontario, February 19. Attendance 65.

Metal Clad-Switchgear, by C. A. Stephens, A. Reyrolle and Company. March 5. Attendance 60.

Utah

The Structure of Atoms, by Dr. Oran Tugman, University of Utah. January 27. Attendance 45.

The Transmission of Photographs over Telephone Wires, by M. B. Long, Bell Telephone Laboratories. February 10. Attendance 70.

Vancouver

Motion Picture, entitled "From Mine to Consumer," was shown. Joint meeting with Engineering Institute of Canada. March 2. Attendance 120.

Washington

Interesting Things about Radio Transmission, by G. C. Southworth, American Telephone & Telegraph Co. Joint meeting with the Washington Academy of Sciences. March 9. Attendance 159.

Worcester

The Quest of the Unknown, by H. B. Smith, Worcester Polytechnic Institute. After the meeting an inspection of the 1,000,000-volt transformer in the laboratory of the Worcester Polytechnic Institute was made. February 23. Attendance 75.

BRANCH MEETINGS

Alabama Polytechnic Institute

Business Meeting. February 3. Attendance 24.

Epoch-Making Engineering Achievement, by Mr. Crawford, student; *The Hudson River, The Tennessee Valley and The Dead Sea Projects*, by Mr. Moore, student; and *Advantages of Electricity on the Farm*, by Mr. Phillips, student. February 18. Attendance 24.

Kv-A. Meters, by Ira Knox, student. February 24. Attendance 16.

Business Meeting. March 3. Attendance 23.

Opportunities of the Engineer Outside of the Big Corporations, by Professor Hill. A motion picture, entitled "Letting Dynamite Do It," was also shown. March 10. Attendance 24.

University of Arizona

The Development of Electrical Production, by Professor Paul Cloke. February 6. Attendance 21.

Motion picture, entitled "The Westinghouse Institution," was shown. February 13. Attendance 19.

Improvement in Laundry Operation, by E. Brooks; *The Mercury Type Wattour Meter*, by W. R. Brownlee; and *The Westinghouse Student Course*, by W. Butler. February 20. Attendance 20.

Proceedings of Society for Advancement of Science, by Professor Paul Cloke; *The New Gas-Electric Truck*, by J. A. Denzer; and *Photographing the Interior of a Rifle Barrel*, by J. W. Cruse. February 27. A motion picture, entitled "A Telephone Call," was also shown. February 27.

University of Arkansas

Motion Pictures, entitled "The Audion" and "Speeding Up on Deep Sea Cables," were shown. February 16. Attendance 32.

Henry Ford's Life and the Ford Industry, by C. W. Collier; and *Need of Increased Efficiency in Use of Coal*, by Gilbert Cecil. March 2. Attendance 19.

Brooklyn Polytechnic Institute

The Operation of the Dial System, by E. H. Goldsmith, New York Telephone Co. February 17. Attendance 42.

University of California

Social Meeting. February 18. Attendance 90.

Carnegie Institute of Technology

The Outlook of the Electrical Industry, by W. E. Caven, student; and *Radio Reception*, by J. R. Balsley, Westinghouse Electric & Mfg. Co. January 20. Attendance 55.

Smoker. February 12. Attendance 100.

Side-Bands in Transatlantic Radio Telephony, by R. F. Riegelmeier, student; and *Conditions Which a Graduate Engineer Must Face after Graduation*, by Fred Coggswell, Pittsburgh Railways Company. March 3. Attendance 23.

Catholic University of America

Motion pictures, entitled "History of the Telephone" and "The Making of a Telephone Desk Set," were shown. February 16. Attendance 20.

University of Colorado

Recent Developments in the Art of Communication, by M. B. Long, Bell Telephone Laboratories. February 15. Attendance 150.

The Possibilities of the Engineering Graduate in Industry, by R. F. Carey, Westinghouse Electric & Mfg. Co. February 16. Attendance 60.

Motion Pictures, showing the plants of the Westinghouse Electric & Mfg. Co., were shown. February 17. Attendance 70.

The Oscillograph, by L. E. Swedlund; *Automatic Substations*, by O. V. Miller; and *High-Voltage Insulators*, by P. M. Brown. March 3. Attendance 110.

University of Denver

High-Temperature Insulation, by Bruce MacCannon. Illustrated with slides. February 3. Attendance 11.

Motion picture, entitled "Temperature and Motor Endurance,' was shown. March 2. Attendance 43.

Drexel Institute

Automatic Motor Control, by F. R. Fishback, Electric Controller and Mfg. Co. February 19. Attendance 50.

University of Florida

The Electrification of Railroads in Chile, by L. S. Boggs, Westinghouse International Co. February 22. Attendance 20.

The Utilization of the Peat Bog of Florida, by Robert Ranson. March 8. Attendance 22.

Georgia School of Technology

A motion picture, entitled "Okonite," was shown. March 2. Attendance 35.

Iowa State College

The Bell System from the Standpoint of an Engineering Student, by L. S. Lambert, Northwestern Bell Telephone Co. March 3. Attendance 95.

Power Station Operation, by J. M. Drabelle, Iowa Railway and Light Co. March 10. Attendance 73.

State University of Iowa

Opportunities at the Bell Telephone Co., by C. W. Davis; and *Listen to Your Speaker*, by J. R. Eyre. February 17. Attendance 43.

Mercury-Vapor Steam Cycle, by W. E. Evitts. February 24. Attendance 38.

Lightning, by K. C. DeWalt; *The Oil-Electric Locomotive*, by S. L. Eppel; and *Engineering-Report Writing*, by E. P. Farrel. March 3. Attendance 42.

Lafayette College

Modern Telephony, by C. L. Craven and P. O. Farnham, students. Illustrated with slides and motion pictures. February 24. Attendance 21.

Lewis Institute

Business Meeting. March 4. Attendance 15.

Marquette University

Railway Signalling, by H. F. Dennett and U. G. Carneiro, students. January 14. Attendance 28.

The Design of Induction Motors, and Their Application, by Frazier Heffrey, Allis-Chalmers Mfg. Co. Illustrated with slides. February 4. Attendance 26.

Massachusetts Institute of Technology

Inspection trip to Edgar Station, at Weymouth, of the Edison Electric and Illuminating Company. March 1. Attendance 31.

University of Michigan

A motion picture, entitled "The Rochester Gas, Electric Light and Power Company," was shown. February 26. Attendance 50.

School of Engineering of Milwaukee

America in the Balances, by James Quarles. A motion picture, entitled "Beyond the Microscope," was also shown. February 23. Attendance 32.

A motion picture, entitled "Wizardry of Wireless," was shown. March 9. Attendance 35.

Missouri School of Mines and Metallurgy

Motion pictures, entitled "Transportation" and "Waterpower," were shown. March 10. Attendance 42.

Montana State College

Carrier Telephony on High-Voltage Power Lines, by W. V. Wolfe, Bell Telephone Laboratories, Inc. February 15. Attendance 161.

Electric Power and Light Utility, by Thomas Heal. February 22. Attendance 154.

University of Nevada

My Experiences in Mexico, by Mr. Johnston. A motion picture, showing college life at the University of Nevada in the year 1914, was shown. February 24. Attendance 40.

College of the City of New York

Business Meeting. The following officers were elected: Chairman, James Wilson; Vice-Chairman, Frank Kulman; Secretary, Joseph Leipziger; Treasurer, E. F. Day; Publicity Manager, Jacob Herson. February 11. Attendance 23.

The Manufacture of Weston Instruments, by Mr. Corby, Weston Electrical Instrument Corp. Illustrated with slides. March 4. Attendance 36.

University of North Carolina

Business and Social Meeting. The following officers were elected: President, M. L. Murchison; Vice-President, G. M. Wilson; Secretary, D. M. Holshouser; Treasurer, F. A. Urbston. February 11. Attendance 34.

University of North Dakota

Life and Work of Oliver Heaviside, by Norman Bue, student. March 8. Attendance 19.

Northeastern University

Some Problems of a Public Utility Company, by L. L. Elden, Edison Electric Illuminating Co. February 15. Attendance 215.

Resistance and Impedance Amplification, by Professor R. G. Porter. February 26. Attendance 42.

Ohio State University

Mr. Allen Smith, Columbus Railway Power and Light Co., gave a talk on his experiences since his graduation in 1923. February 12. Attendance 80.

Oklahoma Agricultural and Mechanical College

A motion picture, entitled "Queen of the Waves," was shown. January 27. Attendance 87.

Pennsylvania State College

Salary Statistics of Alumni, by W. B. Watkeys; *A Study of Engineering Graduates*, by E. R. Queer; and *Adverse Comments on Engineering Prospects*, by John Doe. February 24. Attendance 35.

Purdue University

Distribution Transformers, Their Design, Development and Selection, by E. A. Wagner, General Electric Co. Illustrated with slides. February 25. Attendance 425.

Synchronous Apparatus, by W. T. Berkshire, General Electric Co. Illustrated with slides. March 9. Attendance 50.

Rensselaer Polytechnic Institute

Industrial Control Problems, by H. L. Perdiue, General Electric Co. Illustrated with slides. February 23. Attendance 150.

Rhode Island State College

Flux Linkage vs. Flux Cutting, by Mr. Laycock and Mr. Harvey. January 22. Attendance 16.

Business Meeting. February 5. Attendance 17.

Rose Polytechnic Institute

Motor Applications, by H. W. Rogers, General Electric Co. Illustrated with slides. March 4. Attendance 52.

Rutgers University

Radio Control of Transformers, by Arthur Pahne, General Electric Co. February 8. Attendance 25.

University of South Dakota

Outstanding Developments in the Electrical Industries, by Stverak; and

Developments in High-Voltage Power Transmission, by Mr. Brackett. January 12. Attendance 10.

Developments in Switchboard and Portable Instruments, by Mr. Doohen. Illustrated with slides and motion pictures. February 12. Attendance 71.

University of Southern California

Business Meeting. January 14. Attendance 25.

Business Meeting. The following officers were elected: Chairman, J. H. Shideler; Vice-Chairman, B. L. Iris; Secretary, E. E. Smith; Treasurer, Willard Bausman. January 21. Attendance 27.

Syracuse University

Theoretical Aspects of Conduction in Vacuo and in Gases, by Leroy Mickey. February 15. Attendance 19.

Practical Aspects of Conduction in Vacuo and in Gases, by E. J. Stanmyre. February 22. Attendance 19.

Texas Agricultural and Mechanical College

Induction, by C. M. Thorne, student, February 19. Attendance 65.

University of Texas

Business Meeting. February 11. Attendance 16.

The Midwinter Convention of the A. I. E. E., by Professor J. M. Bryant. February 25. Attendance 20.

Virginia Polytechnic Institute

The Electron Theory, by F. L. Robeson. March 3. Attendance 41.

State College of Washington

Business Meeting. The following officers were elected: President, E. L. Clark; Vice-President, Stanley Bobel; Secretary, Harry Meahl; Treasurer, Mr. Beattie. January 28. Attendance 18.

Washington University

The New KMOX Broadcasting Station, by Mr. McNammie, Kennedy Radio Co. February 4. Attendance 26.

University of Washington

Obstacles Encountered by the Engineer in the Business World, by Glen Smith. February 3. Attendance 25.

The Telephone System, by F. D. Carroll, Pacific Bell Telephone Co. March 4. Attendance 13.

West Virginia University

Inside-Frosted Lamps, by W. F. Davis; *Porcelain Insulators*, by E. H. Braid; *An Epoch-Making Engineering Achievement*, by H. S. Muller; *Electrical Research as Applied to the Phonograph*, by J. W. Schramm; *Hydro-Electric Project in the Tennessee Valley*, by W. A. Williams; *Electric Elevators in Practise*, by K. D. Stewart; *Advantages of Highway Lighting*, by L. S. Davis; *Electric Elevators*, by P. S. Shobe; *A-C. Effects on Telephones*, by G. E. Meintel; *Measuring Sag*, by D. E. Akins; *Dangers Due to Over-Motoring*, by J. Cricchi; *World War Radio*, by A. M. Kalo; *Over-Motoring*, by W. L. Nuhfer; and *Electric-Elevator Practise*, by I. L. Smith. February 19. Attendance 30.

Electric Railways, by R. W. Beardslee; *Engineers at Camp Custer*, by J. U. Neill; *Electrification of N. & W. Railroad*, by E. A. Berry; *Concrete Lighting Poles*, by C. M. Borror; *Recent Oscillograph Developments*, by G. H. Cornell; *Resistance of Electrical Connections*, by G. R. Latham; *Under-Sea Telephones*, by H. S. McGowan; *New Brush-holder*, by A. L. Schneichal; *Tennessee Power Project*, by C. B. Binns; *Two-Winding Motors*, by *W. W. Reed*; *Photo-Electric Cell*, by J. L. Kessinger; *Radiodynamics*, by B. R. Shafer; *Standardization of Electron Tubes*, by W. E. Vellines; and *Electrification of N. Y., N. H., and Hartford Railroad* by R. L. Cole. February 26. Attendance 35.

Electric Transmission for Internal-Combustion Engines, by W. F. Davis; *Mica Insulation*, by E. H. Braid; *Use of Resin in Paper Making*, by H. S. Muller; *Electric Furnaces*, by J. W. Schramm; *How Edison Won the War*, by K. D. Stewart; *Electric Furnace Applications*, by D. E. Akins; *Electrolyzing Glass*, by E. R. Long; *Automatic Office-Building Sub-Stations*, by A. M. Kalo; and *Soldering Aluminum*, by W. L. Nuhfer. March 5. Attendance 28.

Micarta Products, by C. M. Barror; *High-Frequency Currents*, by G. H. Cornell; *Unattended Lighthouses*, by G. R. Latham; *Induction Brass Furnace*, by H. S. McGowan; *Renewing Bearings for Railway Motors*, by A. L. Schmeichel; *Cables on Bear Mountain Bridge*, by C. B. Binns; *High-Torque Synchronous Motors*, by W. W. Reed; *Experiences on the Road*, by L. S. Davis; and *Telephoning Beneath the Sea*, by B. R. Shafer. March 12. Attendance 24.

University of Wisconsin

Electrochemistry—a Factor in Electrical Engineering, by Professor L. Kahlenberg. February 23. Attendance 27.

University of Wyoming

Accident Prevention, by Corlis Van Horne. February 25. Attendance 11.

Yale University

Opportunities in Radio for the Electrical Engineer, by O. E. Dunlap, Radio Editor, *New York Times*. March 9. Attendance 39.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.
53 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.
57 Post St., San Francisco, Calif., N. D. Cook, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to ***EMPLOYMENT SERVICE, 33 West 39th Street, New York City,*** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

DESIGNER, technical graduate, who has had at least two or three years' experience, in design in all kind of transformers of less than 5 K. W. Location, Massachusetts. R-8682.

ELECTRICAL ENGINEER, young, technical graduate, with 2-2½ years' experience, preferably with cable company. Work will be testing and research on cables. Apply by letter. Salary up to $48 a week. Location, New York. R-8851.

SALES ENGINEER, electrical, not over 42, to take charge of syndicate sales. Salary $7500 a year. Apply only by letter. Headquarters, New York City. R-9040.

SALES ENGINEER, to sell heavy machinery to public utilities. Must know public utility trade. Apply only by letter. Salary $6000 a year. Headquarters, New York City. R-9042.

ELECTRICAL SWITCH DESIGNER, for automatic control of direct and alternating current motors. Opportunity. Apply by letter stating technical training, experience, age and required salary. Location, New York City. R-9039.

DRAFTSMEN, under 40, with technical education and several years' experience. Resident of West Philadelphia preferred. Permanent. Opportunity. Apply by letter. Location, Pennsylvania. R-8605.

GRADUATE ELECTRICAL ENGINEER, as technical assistant to engineer in charge of meter work in public utility. Opportunity. Apply by letter with complete details of age, education, training, experience and salary desired with recent photograph. Location, New York City. R-9229.

MEN AVAILABLE

ELECTRICAL ENGINEER, seven years' experience in distribution engineering with two large power companies, desires position with a moderate sized public utility company or industrial concern in the Middlewest. C-964.

SALES ENGINEER, age 26, married, graduate M. I. T., one year construction, three years apparatus design, desires position with a growing concern where a thorough technical knowledge combined with design ability will assist in increasing sales, servicing products, and opening new fields. Employed. Available in one month. Location Anywhere. Minimum $3000. C-307.

CORNELL GRADUATE, E. E. '20, age 27, fourteen months Westinghouse shop and student course, twenty-two months substation operation, nine months test, and twenty-two months general engineering with large public utilities. At present employed. Desires permanent connection with opportunity for advancement. B-4484.

ELECTRICAL ENGINEER, age 32, single, technical graduate, one and one-half years G. E. test, and four years' marine experience. At present chief engineer on Coast Guard destroyer. Desires permanent employment in electrical engineering field with good opportunity for advancement. Available on reasonable notice. Location immaterial. C-396.

ELECTRICAL ENGINEER, age 28, married, eighteen months G. E. Company, six years design, construction and maintenance with electric utilities. Now employed on automatic substation design. Desires permanent connection with utility in Middlewest. Available on thirty days' notice. C-326-308.

SUPERINTENDENT OF ELECTRIC CONSTRUCTION, age 34, married, thoroughly competent to take complete charge of large installations. Six years' actual experience on commercial buildings, city schools, power house and signal stations. Would also consider plant maintenance. Master license. Available immediately. Location, N. Y. B-9638.

PRACTICAL MANUFACTURER AND ENGINEER, married, age 38. Has controlled manufacture and distribution of $250,000,000 of products in eight plants, all of which he reorganized, improved, financed, and managed with resultant increased earnings. He is among the nationally known younger executives. Available within reasonable time. If you desire increased production, distribution, and earnings, write C-699.

ELECTRICAL ENGINEER, age 29, married, graduate Ohio State University in electrical engineering, one and one-half years work in Commerce College, majored in economics and accounting. Experience; two years electrical contracting, and two years sales and production analysis in manufacturing corporation. Available within three weeks' notice. Prefers Ohio or vicinity. B-9865.

ELECTRICAL ENGINEER, age 27, single, speaks, reads and writes fluently English, Spanish and German. Five years' experience in technical, sales and instruction work. Prefers public utility company, or large mining, or metallurgical concern. Location, Mexico or Latin America, preferably Mexico. Salary desired $3000 U. S. currency. C-1027.

RADIO ENGINEER of Spielman Electric Corporation, age 22, single. In radio manufacturing business for himself from 1923-26. Executive ability, and production manager, and designer of sets. Available on two weeks' notice. Location, New York City. C-1020.

ELECTRICAL ENGINEER OR SUPERINTENDENT, age 34, married, eleven years' experience power plant construction, operation and maintenance of same on steam and hydro, including electric railway, substations, power distribution, transmission. Broad experience on industrial electrifications. Can make estimates and layout work. Desires connection with power or engineering company. C-761.

ADVERTISER having twenty years design and construction of power plants, etc., will proceed Pacific Coast permanently this Fall, and desires connection as sales engineer, representative or similar for engineering equipment, electrical or mechanical. Four years with manufacturer's agent abroad handling wide variety engineering apparatus, part of time manager branch office. 41, married, now in New York. B-7371.

PLANT ENGINEER OR MASTER MECHANIC, 39, experienced United States and British steam, gas, hydraulic, electric power plant construction and operation, also industrial and building maintenance. Now employed Middle Northwest, desires good industrial connection. $4000 minimum. Specialty, revamping, harmonizing and maintaining plants up to 5000 K. W. C-987.

ELECTRICAL ENGINEER, 32, college graduate, desires position on general electrical construction, or outdoor substation design. Has had four years of construction, repair and operating experience, three years of drafting and design experience on outdoor substations. Available on two weeks' notice. C-991.

ELECTRICAL ENGINEER, age 31, married, experienced in design, layout, and supervision of construction on indoor and outdoor substations and industrial installations. Location, South America, or Southwest United States. Available fifteen days' notice to present employer. C-1002.

ASSISTANT PROFESSOR OF ELECTRICAL ENGINEERING in strong state university, desires position with progressive, growing educational institution. 34, health excellent, married, eleven years' teaching experience covering all basic and many specialized electrical engineering courses, both theory and laboratory. Experience construction, maintenance with small public utility. Opportunity to do graduate work desirable, but not essential. Available in September. C-1040.

GRADUATE ENGINEER, desires position as chief engineer with concern manufacturing small electrical apparatus, such as motor driven appliances, and also heating devices. Has had experience in design and development, as well as in manufacturing. Age 39. Now employed. A-4660.

MANUFACTURERS' REPRESENTATIVE located in Sydney, N. S. W., Australia, desires additional agencies for American products of electrical and mechanical nature. Technical training, experience, knowledge of conditions. C-798.

ELECTRICAL ENGINEER, graduate Polytechnic Institute of Turin (Italy), 25, single, two years' experience in central station and substation work with the Brooklyn Edison Company. Thorough knowledge relay and protection problems. Desires position with public utility of manufacturing company. Location, vicinity New York. Available on one week's notice. B-8751.

ELECTRICAL ENGINEER, age 44, technical graduate, desires an executive position with public utility, or managment company located in New York City. Last eight years supervised electrical design construction and operation of large mining company in South America. Successful in handling men and interested in personnel work. Available at once. C-1074.

MEMBER A. I. E. E. having connections with important electrical and mechanical concerns abroad for representation in United States, wishes to connect with New York concern to utilize his ability and business relations. B-8609.

INSTRUCTOR ELECTRICAL ENGINEERING, desires for coming (1926-27) collegiate year a change, with promotion to assistant or associate professorship in Eastern or Midwestern university. Man with initiative; ability as teacher. At present teaching the more advanced subjects. Has outgrown present position which can offer no promotion. M. S., B. S. degrees, age 30, married. Eight years' professional and teaching experience. B-3376.

ELECTRICAL ENGINEER, age 27, energetic, inventive and tactful. Past experience, electrical testing and charge of electrical testing apparatus and research. Good references. Desires position developing and research of electrical apparatus or machinery. At present employed, but available on two weeks' notice. Greater New York preferred. B-7270.

INDUSTRIAL ENGINEER, technical, mechanical, electrical engineer, with ten years' practical experience in factory operation, organization and management, wishes change in location. Present position, production manager of factory of twelve hundred employees, branch of one of world's largest corporations. Responsible and in charge of everything except accounting which comes under business manager. C-1070.

ELECTRICAL ENGINEER, age 28, single, wishes position as executive, or assistant electrical engineer. Good character, pleasing personality. German, English, French. Familiar theory and practice electrical and scientific measurements, electrical instruments, meters, relays. Transmission, distribution, protection, dielectric circuits. Three years research laboratory, two years designing. Location, preferably New York. Minimum salary $3500. Available on month's notice. C-930.

ELECTRICAL ENGINEER, age 24, technical graduate, thirteen months G. E. test, year and one-half on electric division of railroad. New York City. Shop experience, testing, inspection, maintenance, cars, locomotives, supervision of car construction, drafting, design. Desires position with power company, industrial, or engineering concern in New York or New England. C-1048.

GRADUATE ELECTRICAL ENGINEER, age 30, with commercial sense, excellent technical training, practical and commercial experience. Familiar with best up to date practice in industrial and central station electrical practice. Available immediately for industrial, or central station engineering management position. Location, North Central States. C-1071.

ELECTRICAL ENGINEERING GRADUATE, with special ability in writing, and the preparation of technical literature, desires position with a manufacturer or distributor of radio equipment, in sales or publicity work. Radio experience before attending college. Available upon graduation in June. Married, 24. Prefers Pacific Coast. C-1067.

CORNELL GRADUATE, with twenty years' experience in design, construction, operation and management of hydro and steam power systems. Now employed, desires change, preferably in New York, San Francisco, or foreign position. Four years in Latin America. Capable of managing entire property, including finances. 39, married. A-3494.

E. E. AND M. E. Graduate, married, six months telephone switchboard installer for Western Electric, one year G. E. test course, one year with a large public utility in the switchboard and substation engineering department, wishes position with future. C-1068.

HIGH GRADE EXECUTIVE AVAILABLE, sixteen years' experience in large and moderate sized electrical and mechanical manufacturing plants in East and Middlewest covering production, equipment, product design, sales and industrial engineering. Engineering education, age 37, married. Employed as departmental manager, but wishes to broaden opportunities. C-1050.

ENGINEER, with twenty years' hydro and steam power plant experience; last ten years in management, four years in Latin America. Cornell training. Now employed. Prefers New York, San Francisco, or foreign position. A-3494.

DEVELOPMENT OR PRODUCTION ENGINEER, age 37, married, graduate M. I. T. electrical engineering. Experience covers manufacture small electrical apparatus, trouble shooting on assemblies, specification writing, technical correspondence, laboratory work organizing manufacture of delicate A. C. measuring apparatus. Have canvassed for sales. Can be of service on development of electrical specialties, or on production working between development engineers and factory. Available at once. Location, New York City. C-1018.

ELECTRICAL ENGINEER, age 28, single, technical graduate, desires position with manufacturer electrical apparatus. Five years' experience with engineering department of large company manufacturing industrial control equipment. A little sales experience. Minimum salary $2500. Available on reasonable notice. B-6274.

ELECTRICAL ENGINEERING GRADUATE, age 30, now student at a prominent university, accurate with mathematical calculations, desires summer work with engineering firm in New York. Can do drafting, but prefers engineering calculations. Available about July 1st. to September 30th. B-7526.

ENGINEER, 27, married, Stanford graduate, 1920, mechanical engineering. One year managing engineer gas and fuel company, five years engineering department, desires business end of engineering position. Can make investment. Available at once. Location, California. C-1057-2-C-10.

PRACTICAL ELECTRICAL AND TELEPHONE SUPERINTENDENT, age 38, construction, reconstruction, operation or maintenance; nine years Latin America. Returning to States on account of schooling for children. References. C-1088.

WORKS MANAGER-EXECUTIVE ENGINEER, post graduate electrical engineer, age 43, twenty years engineering, shop management, sales; development engineer, Westinghouse, six years, manager five years manufacturing department large electrical company. Traveled abroad, negotiating important contracts. Now executive engineer, assisting sales reorganization old established concern. Consider only managing position. Would go abroad. Salary $7500. C-30.

TECHNICAL GRADUATE IN ELECTRICAL ENGINEERING, age 32, married, desires a position with a public utility having an underground cable system. Very familiar with cable failure locating devices, U. G. operating problems, electrolysis surveys. Absolutely reliable and hard worker. Willing to go anywhere. Available anytime with reasonable amount of notice to present employers. C-1093.

MECHANICAL-ELECTRICAL ENGINEER, age 30, mechanical engineering graduate 1916, two years of plant equipment supervision, three years of research and design in radio for Navy Department, three years as assistant to consulting engineer with general practice. Has spent eighteen years actively in radio field. Desires position giving sales training, no objection to traveling. Minimum salary $3000. Available after notice of one month. C-2003.

1925 GRADUATE ELECTRICAL ENGINEER, Georgia Tech, Age 24, sales and business experience, desires position with possibilities for advancement with public utility, or electrical contracting company. Location, preferably Florida or Georgia. C-2004.

ENGLISH CONSTRUCTION ENGINEER, age 38, with wide factory and power station experience, desires responsible position abroad. Accustomed to tropical climates and handling of native labor. C-1092.

LEMAIRE, ARTHUR EDWARD, Resident Electrical Engineer, Water Conservation & Irrigation Commission, Leeton, New South Wales, Aust.

*LEONARD, ROBERT NORMAN, Electrical Tester, New York Edison Co., 92 Vandam St., New York; res., Port Richmond, N. Y.

LEWIS, WILLIAM KENNETH, Asst. Sales Engineer, Messrs. Ferguson Pailin, Ltd., 37 Norfolk St., Strand, London, W. C. 2, Eng.

LINDBLOM, ROY E., Instructor, Elec. Engg. Dept., University of Washington, Engg. Hall, Seattle, Wash.

*LONG, FOREST ALDEN, Engineer, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

*LONG, PAUL BARTLEY, Signal Engineer, Union Switch & Signal Co., Swissvale, Pa.
LORICH, ROLAND ALBERT, Asst. Engineer, New York & New Jersey State Bridge & Tunnel Commission, Woolworth Bldg., New York, N. Y.
LOSHBOUGH, LINN, Engineer, General Electric Co., Illinois Merchants Bank Bldg., Chicago, Ill.
LOVE, EDGAR LEE, Methods Engineer, Test Engineers Dept., Western Electric Co., Inc., 268 W. 36th St., New York, N. Y.
LUND, ARVE, Designer, Stone & Webster, Inc., 147 Milk St., Boston, Mass.
LUNDGREN, FLOYD EDWARD, Chief Engineer, General Electric, S. A., Mexico, D. F., Mexico
MAHEU, JAMES JOSEPH, Methods Engineer, Western Electric Co., Hawthorne Sta., Chicago, Ill.
*MANSPEAKER, EDWIN DIEHL, Student Engineer, General Electric Co., Schenectady, N. Y.
MANY, WILLIAM G., Managing Editor, Radio Review, 53 Park Place, New York, N. Y.
MARKERS, HAROLD WALTER, Junior Engineer, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
MARTIN, EDMUND JOSEPH, Tester, General Electric Co., Bloomfield; res., East Orange, N. J.
MASUNO, TAJIRO, Electrical Designer, Stone & Webster, Inc., 147 Milk St., Boston, Mass.
MAUSSHARDT, M. R., Electrician, Key System Transit Co., Oakland; res., San Francisco, Calif.
McCLARREN, ARTHUR EDWARD, Meter Dept., Puget Sound Power & Light Co., 7th & Olive, Seattle, Wash.
McGEE, JESSE SCOTT, Dist. Supt., Monongahela West Penn Public Service Co., Grafton W. Va.
McGOWAN, LEON F., Drafting, Rochester Gas & Elec. Co., Rochester, N. Y.
*McKINLEY, JOHN LINK, Engineer, Public Service Co. of Colorado, 900 15th St., Denver, Colo.
McLEAN, JOHN, Line Extension Estimator, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*MERCEREAU, JAMES TIMOTHY, Student, Westinghouse Elec. & Mfg. Co., 139 2nd St., East Pittsburgh, Pa.
*MERRILL, MARCELLUS S., Switchboard Engg. Dept., General Electric Co., Schenectady, N. Y.
METZ, JOHN, Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*MICHAEL, JOHN JOSEPH, Draftsman, Pacific Tel. & Tel. Co., 800 Fairview Ave., Seattle, Wash.; for mail, Portland, Ore.
*MILLER, FREDERICK HERBERT, Electrical Work, Franz A. Boedtcher, 442 W. 42nd St., New York, N. Y.
*MILLER, JOHN H., Salesman, Firestone Tire & Rubber Co., Johnstown; res., Pittsburgh, Pa.
*MILLER, RALPH F., Graduate Student, Educational Dept.: Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Reading, Pa.
MILLER, RUSSELL F., Electrical Engineer, Naomi Pines Electric Co., Inc., Pocono Pines, Pa.; res., Brooklyn, N. Y.
*MILLER, WILLIAM HAROLD, Radio Mechanic, Canadian Westinghouse Elec. & Mfg. Co., 366 Adelaide St., W., Toronto, Ont., Can.
MISNER, FRANCIS D., Elec. Draftsman, Commonwealth Pr. Corp., 1318 Wildwood Ave., Jackson, Mich.
MITCHELL, JAMES IAN, Asst. System Operator, Public Service Co. of No. Illinois, 908 Clark St., Evanston, Ill.
*MIYASAKI, MASAO, Research Assistant, University of Wisconsin, 740 Langdon St., Madison, Wis.
MIZELL, MAXWELL HOWARD, Lieut. U. S. Marine Corps, Marine Corps Headquarters, Washington, D. C.
MODE, HERBERT CONLEY, Salesman, Westinghouse Elec. & Mfg. Co., 30th & Walnut Sts., Philadelphia; res., Merion, Pa.
MONACO, JOSEPH, Electrician, M. R. Greenblatt, 198 7th Ave., Brooklyn, N. Y.
*MUTH, LAWRENCE RINHOLDT, Jr., Electrical Draftsman, City of Seattle, 204 County City Bldg., Seattle, Wash.
MUUSFELDT, AXEL, Draftsman, Public Service Co. of Illinois, 79 Monroe St., Chicago, Ill.
*MYERS, FRANK WILLIAM ALOYSIOUS, Electrical Inspector, Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.
NELSON, NELS, Assistant Electrical Engineer, Adirondack Power & Light Corp., Clinton St., Schenectady, N. Y.
NIGHTINGALE, RICHARD, Electrical Engineer, Light Dept., City of Tacoma, City Hall, Tacoma, Wash.
NOERR, ALBERT EDWARD, Electrical Engineer, Noerr Electric Service, Suva, Fiji Islands.
OAKE, CYRIL JOSEPH, Deputy Electrical Engineer & Manager, British Municipal Council, Tientsin, N. China.
OLDS, CLARENCE DUDLEIGH, Distribution Engineer, Puget Sound Power & Light Co., 301 E. Holly, Bellingham, Wash.
OROPESA, PATRICIO, Sub-Director, Escuelade Ingrs, Mecanicos, Electricistas, Allende No. 38, Mexico D. F., Mex.
*ORTLIEB, OTTO PAUL, Street Lighting Engineer, City of Trenton, 307 Municipal Bldg., Trenton, N. J.; res., Philadelphia, Pa.
OTTO, EMIL DITMAR, Asst. Manager, Radio Dept. Royal Eastern Electrical Supply Co., 114 W. 27th St., New York, N. Y.
*OVER, HAROLD A., Engineer, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*PALMER, GAIL W., Chief Draftsman, L. D. Smith Dock Co., Sturgeon Bay, Wis.
PATTERSON, EDWARD BELL, Asst. Radio Editor, "Public Ledger" & "Evening Ledger," Independence Square, Philadelphia, Pa.; res., Merchantville, N. J.
*PENNYBACKER, MILES, Sales Engineer, Raytheon Mfg. Co., 292 Main St., Cambridge, Mass.
PERRY, DANIEL J., Engineering Assistant, Bell Telephone Co. of Pa., 261 N. Broad St., Philadelphia, Pa.
PETERSON, VANCE CLIFFORD, Chief of Planning Section, Western Electric Co., Cicero; res., Chicago, Ill.
PETTET, CECIL CHARLES, Inspection Engineer, Northern Electric Co., Ltd., 131 Sherer St., Montreal, P. Q., Can.
*PHILLEO, EDWARD WEST, Director of Pacific Coast Educational Dept.; Victor X-Ray Corp., 254 Sutter St., San Francisco; res. Oakland, Calif.
PRICE, ARTHUR VALLEAU, Florida Power & Light Co., Daytona Beach, Fla.
*PRUDHOMME, DONALD JAMES, Student, Oregon State College, 320 N. 9th St., Corvallis, Ore.
PUTNAM, RUSSELL CALDWELL, Instructor, Dept. of Elec. Engg., Case School of Applied Science, Cleveland, Ohio.
RANKIN, HARRY CURTIS, General Tester, The New York Edison Co., 708 1st Ave., New York, N. Y.
REILLY, FRANK WILLIAM, Asst. Electrical Engineer, Carleton-Mace Engineering Corp., 10 High St., Boston; res., Atlantic, Mass.
REIMEL, SAMUEL ROY, Asst. Test Engineer, B. F. Goodrich Co., Akron, Ohio.
*RICE, JANVIER MAYHEW, Instructor, Dept. of Mathematics, Pennsylvania State College, State College, Pa.
*RICHARDS, F. IRA, Student Engineer, General Electric Co., Schenectady, N. Y.
RIEMAN, HARRY MARTIN, Distribution Div., Engg. Dept., Central Hudson Gas & Electric Co., 50 Market St., Poughkeepsie, N. Y.
RODEWIG, LOUIS FREDERICK, Estimator, General Electric Co., 120 Broadway, New York, N. Y.
ROGER, WILLIAM HUGH GREGORY, Electrical Drafting c/o Fraser, Frew & Dryer, Ltd., 448 Seymour St., Vancouver, B. C., Can.
ROSE, DONALD L., Station Electrician, Southern California Edison Co., Power House No. 3, Big Creek, Calif.
ROWLEY, CLYDE, Substation Operator, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*RUPPELL, EDWARD AUGUST, Manager, Grand Central Electric Corp., 247 Park Ave., New York; res., Hart Park, N. Y.
SAFDAR, H., Power Controller, G. I. P. Railway, Matunga, Bombay, India.
SASSEN, CHARLES H., Supt. Elec. Maintenance & Construction, Hudson Coal Co., Scranton, Pa.
SCHAEFER, PHILIP EMIL, Job Supervisor, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*SCHROEDER, HENRY WILLIAM, Tester, Commonwealth Edison Co., 28 N. Market St., Chicago, Ill.
SCHULTZ, HERBERT GORDON, Supervisor, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
SCOTT, CARL, Electrical Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
SEDERBERG, NORMAN W., Generating Station Operator, Brooklyn Edison Co., Gold St. Generating Station, Brooklyn; res., New York, N. Y.
SEELYE, ALBERT F., Chief Electrician, Boise Payette Lumber Co., Barber, Idaho.
SHARPSTEEN, JOHN LUCIUS, Draftsman, Pacific Gas & Electric Co., 447 Sutter St. San Francisco; res., Alameda, Calif.
SHULZE, GEORGE FRANKLIN, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Maplewood, N. J.
*SHUMAN, URIAH SIDNEY, Asst. Supt. of Distribution, Philadelphia Suburban Gas & Electric Co., Newtown, Pa.
SIBLEY, WILLIAM CHARLES, Chief Operator, Substation, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
SISLER, FRANK G., Final Tester, The Electric Controller & Mfg. Co., 2700 E. 79th St., Cleveland, Ohio.
SMITH, ARNE CHRISTOPHER, Electrical Engineer, Development & Test Dept., Otis Elevator Co., 1 Woodworth Ave., Yonkers, N. Y.
SMITH, CHARLES LAURENCE, Foreman Electrician, C. H. E. Williams & Co., Ltd., Vancouver, B. C., Can.
SMITH, H. WYLIE, Testing Dept., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
SMITH, JOE L., Cable Engineer, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
SMITH, OLIVER, Electrical Draftsman, Thomas E. Murray, Inc., 55 Duane St., New York; res., Corona, N. Y.
*SMITH, VICTOR GEORGE, Research Assistant, University of Toronto, Toronto, Ont., Can.
SMITH, WILLIAM J., Inst., Calibrator, Commonwealth Edison Co., 28 N. Market St., Chicago, Ill.
*STAHL, CHOUTEAU PLATT, Student Engineer, General Electric Co., Schenectady, N. Y.
STARR, ARNOLD L., Sales Engineer, Clapp & LaMores, 310 E. 4th St., Los Angeles, Calif.

STOCK, ROBERT JOHN, Supervisor, Electrical Equipment, 604 Gwynne Bldg., Cincinnati, Ohio.
*STORY, THEODORE HARVEY, Acting Supt. of Construction, Turner Construction Co., 244 Madison Ave., New York; res., Brooklyn, N. Y.
STOVER, JAMES R., Electrical Designing Engineer, Metropolitan Edison Co., 16 S. Fifth St., Reading, Pa.
*STOVER, MERRILL McCORD, General Engineering Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.; res., Elmhurst, N. Y.
STOWERS, LOUIS G., Equipment Engineer, Southern Bell Tel. & Tel. Co., Atlanta, Ga.
SUDLER, EDWARD O., Instructor, Bliss Electrical School, Takoma Park; res., Washington, D. C.
SYKES, PAUL MISCHLER, 1510 S. Center St., Terre Haute, Ind.
TAGGART, CHARLES W., General Manager, City of Norwich Gas & Elec. Dept., 34 Shelucket St., Norwich, Conn.
TALLIANOS, PETER C., Professor of Mathematics & Physics, Greek Academy, Alexandria, Egypt.
*TARZIAN, SARKES, Radio Laboratory, Atwater Kent Mfg. Co., 4713 Wissahickon Ave., Philadelphia, Pa.
TAYLOR, FLOYD F., Power Plant Operator, Salt River Valley Water Users Association, Lake Side Club, Roosevelt, Ariz.
TEAGUE, JOHN A., Chief Electrician, Baker Iron Works, 950 N. Broadway, Los Angeles, Calif.
THOMAS, CECIL HUBERT, Technical Assistant, Electrical Testing Laboratories, 80th St. & East End Ave., New York, N. Y.
*THOMPSON, ALBERT CLARK, Engineer, Dept. of Dev. & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
THOMPSON, GEORGE SILAS, Chief Electrician, Fuel Dept.; Supt., New Power Plant, Colorado Fuel & Iron Co., Pueblo, Colo.
*THOMPSON, HARRY E., Inspector, Brooklyn Edison Co., 360 Pearl St., Brooklyn, N. Y.
THOMSON, THOMAS B., Supt., Maintenance Dept., U. S. E. M. Co., 505 W. 42nd St., New York, N. Y.; res., Union City, N. J.
*THORSON, WILBUR RAYMOND, Distribution Engineer, Consumers Power Co., Kalamazoo, Mich.
*THURSTON, HOWARD ALLEN, Electrician, Columbus Railway, Power & Light Co., 209 N. Front St., Columbus, Ohio.
TIETZ, WILLIAM J., Methods Engineer, Western Electric Co., Hawthorne Station, Chicago, Ill.
TISDALE, WALTER H., Illuminating Engineer, Connecticut Power Co., Middletown, Conn.
TORGAN, NATHAN, Jr., Sales Engineer, Horni Signal Mfg. Corp., 153 Frelinghuysen Ave., Newark, N. J.; for mail, Providence, R. I.
TRIMBLE, LOREN, Operator, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
TRONE, EDWARD M., Electrical Engineer, Western Electric Co., Inc., Chicago; res., Brookfield, Ill.
TURNER, HAROLD ELLIOT, Central Station Engineer, General Electric Co., Schenectady, N. Y.
*VAN SICKLE, ROSWELL C., Design Engineer, Westinghouse Elec. & Mfg. Co., Wilkinsburg, Pa.
WALKER, FRANK VICTOR, Senior Operator, San Fernando Plant, Bureau of Power & Light City of Los Angeles, San Fernando, Calif.
WALLIS, CHARLES G., Industrial Control Design, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.
WALWORTH, STANLEY LINCOLN, Dist. Sales Representative, Pittsburgh Transformer Co., Columbus & Preble Aves., Pittsburgh, Pa.
*WEBER, HANARD P., Exciter Operator, Fisk St. Station, Commonwealth Edison Co., 22nd & Fisk Sts., Chicago, Ill.
WEST, GEORGE HARRISON, Station Electrician, Louisiana Electric Co., Inc., Lake Charles, La.
*WESTBROOK, JOHN LEWIS, Supt. Meter Dept., Compania Agricola 7 de Fuerza Electrica del Rio Conchos, S. A., C., Cia Agricola, C. Camargo, Chih., Mex.
WESTERMAN, A. G., Job Supervisor, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
WESTHOVEN, CASPER JOSEPH, Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
WHITAKER, EDWARD R., Electrical Foreman, Union Electric Light & Power Co., Ashley Sta., St. Louis, Mo.
WICK, RAYMOND JOSEPH, Tester, Commonwealth Edison Co., 28 N. Market St., Chicago, Ill.
WILBUR, DONALD ELDREDGE, Radio Operator, Pennsylvania Power & Light Co., Front St. Power House, Allentown; res., Bethlehem, Pa.
WILCOX, JOHN EDWIN, Chief Switchman, New York Telephone Co., 227 E. 30th St., New York; res., Brooklyn, N. Y.
WILLIAMS, ANEURIN TUDOR, Chief Operator, Hydro-Electric Power Station, Newfoundland Power & Paper Co., Ltd., Deer Lake, Newfoundland.
WILLIAMS, GURDON HUNTER, Road Engineer, Service Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
WILLIAMS, NIAL B., Chief Operator, Jefferson St. Power House, Puget Sound Power & Light Co., 423 7th Ave., Seattle, Wash.
*WINOGRAD, HAROLD, Electrical Engineer, American Brown Boveri Electric Corp., Camden, N. J.
WISHARD, WILLIAM W., Asst. Chief Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
WOLF, RICHARD, Jr., Student of Elec. Engg., Bahnhofstr 19, Mittweida, Sa., Germany.
*YOUNG, PAUL NATHAN, Technical Estimator, Detail & Record Bureau, Brooklyn Edison Co., Inc., 360 Pearl St., Brooklyn, N. Y.
*ZIMMER, FREDERIC M., Distribution Engineer, Ohio Power Co., 720 2nd St., S. E., Canton, O.

Total 280

*Formerly enrolled students

ASSOCIATES RE-ELECTED MARCH 19, 1926

ALTAMIRANO, SALVADOR E., General Manager, General Electric S. A., Mexico D. F., Mex.
DuBOIS, ALEXANDER DAWES, Engg. Dept., Electric Machinery Mfg. Co., 14th & Tyler St., N. E., Minneapolis, Minn.
MOLINA, F. JULIO, Electrical Engineer, Calle 59 No. 447, Merida, Yucatan, Mex.

MEMBERS ELECTED MARCH 19, 1926

ALLEN, LOUIS MICHAEL, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
BAXTER, NORMAN McLEOD, Engineer, The Ohio Public Service Co., Sandusky, Ohio.
CALL, CHARLES ARTHUR, Inspector, Ohio Insulator Co., Barberton, Ohio.
CRAMP, WILLIAM, Professor of Elec. Engg., University of Birmingham, Edgvaston, Birmingham, Eng.
HECHT, JULIUS L., Vice President, Public Service Co. of No. Ill., 72 W. Adams St., Chicago, Ill.
HORGAN, JAMES GALVIN, General Power Sales Engineer, Ohio Public Service Co., Cleveland, Ohio.
KNOST, JOHN HENRY, Jr., Engineer, Power & Industrial Dept., Westinghouse Elec. & Mfg. Co., 420 S. San Pedro St., Los Angeles, Calif.
KOPP, OTTMAR HUGO, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
ROUGHEN, RICHARD HARVEY, Supt., Sub-Sta. Dept., Duquesne Light Co., 435 Sixth Ave., Pittsburgh, Pa.
VICKERS, HERBERT, Professor of Elec. Engg., Head of Dept. of Mech. Engg., University of British Columbia, Vancouver, B. C., Can.

TRANSFERRED TO GRADE OF FELLOW MARCH 19, 1926

COATES, WILLIAM A., Metropolitan Vickers Electrical Export Co., Tokyo, Japan.
DIXON, AMOS F., Systems Development Engineer, Bell Telephone Laboratories, New York, N. Y.
McIVER, GEORGE W., Jr., Asst. Manager, Electrical Dept., Toledo Edison Co., Toledo, O.
THOMS, ALEXANDER P., Asst. Supt., Street Department, Commonwealth Edison Co., Chicago, Ill.
WILLIAMS, SAMUEL B., Telephone Engineer, Bell Telephone Laboratories, New York, N.Y.

TRANSFERRED TO GRADE OF MEMBER MARCH 19, 1926

ADKERSON, BRANCH O., Inside Plant Engineering, American Tel. & Tel. Co., New York, N. Y.
AMBUHL, FRANK F., Asst. Chief Engineer, Toronto Hydro-Electric System, Toronto, Ont., Can.
ARCEO, ANTONIO, Supt. of Distribution, Mexican Light & Power Co., Ltd., Mexico City, Mex.
BANNISTER, ALBERT, Chief Assistant, Switchgear Sales Dept., Metropolitan Vickers Electrical Co., Ltd., Manchester, Englnd.
BELL, JOHN H., Telegraph Engineer, Bell Telephone Laboratories, New York, N. Y.
BOSTATER, HERBERT L., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.
DAVIS, URIAH, Load Dispatcher, Commonwealth Edison Co., Chicago, Ill.
EASTHAM, MELVILLE, President and Engineer, General Radio Co., Cambridge, Mass.
ENGLE, MELVIN D., Engineer, Station Engineering Dept., Edison Electric Illuminating Co. of Boston, Boston, Mass.
EVANS, ROBERT D., General Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.
FRIEND, HENRY M., Cable Engineer, Hugh L. Cooper & Co., New York, N. Y.
GARY, LAURENCE A., Engineer, Transmission Dept., Pacific Tel. & Tel. Co., San Francisco, Calif.
HASTINGS, MILTON B., Vice-President, Powerlite Devices, Ltd., Toronto, Ont., Can.
INNES, FRANK R., Asst. Editor, "*Electrical World*," New York, N. Y.
KERSEY, GLEN B., Field Engineer, Commonwealth Edison Co., Chicago, Ill.
McDOWELL, H. E., Electrical and Mechanical Engineer, Texas Power & Light Co., Dallas, Tex.
NASH, JOHN F., Electrical Engineer and Division Manager, Appalachian Power Co., Bluefield, W. Va.
RADER, RAY, Assistant Engineer, Puget Sound Power & Light Co., Seattle, Wash.
ROBERTS, SPENCER, Engineer, Day & Zimmerman, Philadelphia, Pa.
SCOFIELD, EDWARD H., Engineer of Power, Twin City Rapid Transit Co., Minneapolis, Minn.
SMITH, GEORGE S., Instructor of Electrical Engineering, University of Washington, Seattle, Wash.
STEVENS, THEODORE, Consulting Engineer, London, England.
VANHALANGER, L. J., Sales Engineer, Westinghouse Electric & Mfg. Co., Chicago, Ill.

WAY, HOWARD E., Special Agent, Electrical Equipment Div., Bureau of Foreign and Domestic Commerce, Washington, D. C.

WREAKS, HUGH T., Manager, Detroit Office, Boston Insulated Wire & Cable Co., Detroit, Mich.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held March 8, 1926, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

DWIGHT, HERBERT BRISTOL, Professor, Massachusetts Institute of Technology, Cambridge, Mass.

HEINZE, CARL A., Electrical Engineer in charge of Distribution, Department of Water & Power, City of Los Angeles, Los Angeles, Calif.

OEHLER, ALFRED G., Editor—Railway Electrical Engineer, Electrical Editor—*Railway Age*, New York, N. Y.

To Grade of Member

ANDERSON, EDWARD T., Electrical Engineer, Board of Water & Electric Light Commissioners, Lansing, Mich.

BACKUS, CYRUS D., Principal Examiner, U. S. Patent Office, Washington, D. C.

BOHNERT, ARTHUR M., District Engineer, Ohio Brass Co., San Francisco, Calif.

BOLLINGER, HOWARD M., Supervisor of Plant Methods, Chesapeake & Potomac Telephone Co., Washington, D. C.

Brockway, R. M., Engineer, Switchboard Dept., General Electric Co., Schenectady, N. Y.

CARPE, ALLEN, Engineer, Dept. of Development & Research, American Telephone & Telegraph Co., New York, N. Y.

CLAPP, ROBERT H., Telegraph Engineer, American Telephone & Telegraph Co., New York, N. Y.

COLBURN, WELLEN H., Electrical Engineer, Station Engineering Dept., Edison Electric Illuminating Co. of Boston, Boston, Mass.

CRESSEY, JOHN A., Control Engineer, South Wales Power Co., Upper-Boat Power Station, Treforest, Pontypridd, Glamorgan, England.

FINCH, WILLIAM G. H., Radio Editor and Engineer, International News Service, New York, N. Y.

GIBSON, E. S., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.

HEILBRUN, RICHARD Head of Firm, Dr. Richard Heilbrun, Manufacturer of Electric Appliances, Berlin, Germany.

JACKSON, DUGALD C., JR., Asst. Professor of Electrical Engineering, Trinity College, Durham, N. C.

RAMIREZ, JAVIER P., Consulting Engineer, Professor—Escuela de Ingenieros Mecanicos Electricistas, Mexico City, Mex.

RORTY, M. C., President International Telephone Securities Corp.—Vice-President, International Tel. & Tel. Corp., New York, N.Y.

SAATHOFF, GEORGE W., Chief Construction Engineer, Henry L. Doherty & Co., New York, N. Y.

SPORN, PHILIP, Assistant to Electrical Engineer, American Gas & Electric Co., New York, N. Y.

SPRACKLEN, EMERY E., Electrical Engineer in charge of Design, Ohio Public Service Co., Massillon, Ohio.

TAYLOR, NEWTON S., Manager, Switchboard Section, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

WARFIELD, S. C., President & Engineer, M. O. & W. Engineering Corp., Morton, Va.

WHIPPLE, CLYDE C., Asst. Professor of Electrical Engineering, Polytechnic Institute, Brooklyn, N. Y.

APPLICATIONS FOR ELECTIONS

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before April 30, 1926.

Allen, T. D. N., U. S. Veterans' Bureau, Washington, D. C.
Allen, T. S., (Member), Allis-Chalmers Mfg. Co., Milwaukee, Wis.
Andrews, S. W., Foundation Co., Pittston, Pa.
Ballew, R. E., Great Western Power Co., Oakland, Calif.
Banton, F. B., New Orleans Public Service Co., New Orleans, La.
Becker, F. A., Canadian General Co., Toronto, Ont., Can.
Beckett, W., (Member), Georgia Railway & Power Co., Atlanta, Ga.
Berting, G. A., The North Electric Mfg. Co., Galion, Ohio
Bettinger, L.W., U. S. S. Concord, c/o Postmaster, New York, N. Y.
Blenkarn, W. O., Salt Creek Electric Plant, Midwest, Wyoming
Beyrodt, K., Bond Service Repair Co., New York, N. Y.
Bodelsson, A. Pratt Institute, Brooklyn, N. Y.
Brown, H. H., Wisconsin Trac. Lt. Ht. & Pr. Co., Appleton, Wis.
Brown, R. E., Rhode Island State College, Kingston, R. I.
Burdin, A. J., Western Electric Co., Hawthorne Sta., Chicago, Ill.
Burkhardt, C. E., Municipal Power & Ice Plant, Sebastian, Fla.
Cady, W. M., Development Work, 108 Clinton Ave., Newark, N. J.
Carolan, W. A., 712 Putnam Ave., Brooklyn, N.Y.
Carpenter, H. W., Sangamo Electric Co., Boston, Mass.
Cates, R. V., American Tel. & Tel. Co., Charlotte, N. C.
Chant, A. E., Dept of Telephones, Regina, Sask., Can.
Clark, O. S., Union Gas & Electric Co., Cincinnati, Ohio
Clarke, P. C., General Electric Co., West Philadelphia, Pa.
Colvin, A. L., Lockport & Ontario Power Co., Angola, Ind.
Csepely, J. A., The Western Electric Co., Inc., New York, N. Y.
Crawford, W. K., Brooklyn Edison Co., Brooklyn, N. Y.
Davis, A. E. H., Frank J. Yorke Co., Detroit, Mich.
Davis, H. F., Monongahela West Penn. Public Service Co., Fairmont, West Va.
DeDona, A. J., Postal Telegraph Co., New York, N. Y.
de Zamacona, L., Mexican Light & Power Co., Mexico City, Mex.
Dreyfus, J., New York Tel. Co., Brooklyn, N. Y.
Duncanson, P., Western Electric Co., Kearny, N. J.
Dunstan, R. A., General Electric Co., Schenectady, N. Y.
Eighmy, G. W., General Electric Co., Buffalo, N.Y.
Ellis, C. R., Louis T. Klauder, Philadelphia, Pa.
Elword, A., (Member), C. M. & S. Co., Ltd., Trail, B. C., Can.
Engelken, R. C., Brooklyn Edison Co., Brooklyn, N. Y.
Engh, J. S., Automatic Electric, Inc., Chicago, Ill.
Farrell, J. J., Great Western Power Co., Caribou Plumas Co., Calif.
Fleshiem, R. S., Allis-Chalmers Mfg. Co., Milwaukee, Wis.
(Applicant for re-election)
Flory, A. C., (Member), Allis-Chalmers Mfg. Co., Milwaukee, Wis.
Foltz, J. P., Westinghouse Elec. & Mfg. Co., Wilkinsburg, Pa.
Forkel, W. H., Metropolitan Electr. Manufacturing Co., Long Island City, N. Y.
Foster, H. B., Wireless Specialty Apparatus Co., Boston, Mass.
Fowler, J. R., Westchester Lighting Co., Mt. Vernon, N. Y.
Galer, F. C., Lancashire Dynamo & Motor Co., Toronto, Ont., Can.
Gigat, A. W., (Member), Granby Consolidated Mining, Smelting & Pr. Co., Anyox, B. C., Can.
Haddock, C. C., Brooklyn Edison Co., Brooklyn, N. Y.
Haig, C. M., New England Tel. & Tel. Co., Boston, Mass.
Hankey, W. J., The Cleveland Railway Co., Cleveland, Ohio
Harrington, G. W., Pratt Institute, Brooklyn, N.Y.
Harrison, A. T., Pacific Gas & Electric Co., Cassell, Calif.
Hepinstall, W. G., Lignite Utilization Board, Bienfait Sask., Can.
Herrera, R. O., General Electric Co., Schenectady, N. Y.
Hindman, E. R., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Holton, T. R., 62 West Street Worcester, Mass.
Hudson, A., General Electric Co., Schenectady, N. Y.
Hudson, F. E., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Hughes, G. O., Bureau of Pr. & Lt., City of Los Angeles, Saugus, Calif.
Ishii, T., Japanese Government Railways, New York, N. Y.
Jeannin, H. W., (Member), The Jeannin Electric Co., Toledo, Ohio
Jones, F. A. M., The Pacific Tel. & Tel. Co., San Franscisco, Calif.
Jones, J. P., Consulting Engineer, Cleveland, Ohio
Jund, D., with W. C. Lagerway, New York, N. Y.
Kelhofer, L. M., Commonwealth Power Corp., Jackson, Mich.
Khalifah, A. A., Baldwin Locomotive Works, Philadelphia, Pa.
Klein, F. A., Public Service Electric & Gas Co., Newark, N. J.
Kovalsky, J. F., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Kovediaeff, B. E., 1018 W. 73rd St., Los Angeles, Calif.
Kupferle, A. T., Union Gas & Electric Co., Cincinnati, Ohio
Lamantia, J. C., Brooklyn Polytechnic Institute, Brooklyn, N. Y.
Lappin, J. L., General Electric Co., Bloomfield, N. J.
Lauth, E. H., Street Lighting Sec., City of St. Louis, St. Louis, Mo.
Lewis, F. M., Northwestern Electric Co., Portland, Ore.
Mahood, E. T., Southwestern Bell Telephone Co., St. Louis, Mo.
(Applicant for re-election)
Manning, E. R., Weston Electrical Instrument Corp., New York, N. Y.
Markovits, J. A., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Marshall, A. E., The Philadelphia Electric Co., Philadelphia, Pa.
Martini, J. A., Postal Telegraph Co., New York, N. Y.
McGinnis, N. W., H. C. Reid & Co., San Francisco, Calif.
McGrath, M. H., Standard Underground Cable Co., Pittsburgh, Pa.
McIntyre, R. J., Gray Electric Chemical Laboratory, Bayonne, N. J.
McKeon, J. B., Rochester Gas & Electric Corp., Rochester, N. Y.
McLean, J. S., (Member), J. G. White Engineering Corp., New York, N. Y.
Mimmack, A., City Electrician, City Hall, Beverly Hills, Calif.

Mororo, D. G., 513 W. 145th St., New York, N. Y.
Morse, A. W., The Pacific Tel. & Tel. Co., San Francisco, Calif.
Moss, J. E., West Penn Power Co., Washington, Pa.
Murphy, J. A., McClellan & Junkersfeld, Inc., St. Louis, Mo.
Nemetz, V. W., Commonwealth Power Corp., Jackson, Mich.
Nerges, F. A., U. S. S. Owl, No. 2, Hampton Roads, Va.
Overfield, G. B., Burke Electric Co., Erie, Pa.
Panton, H. A., Buffalo General Electric Co., Buffalo, N. Y.
Pasayiotis, G. N., Book-News & Novelty Co., Reading, Pa.
Petersen, H. N., Great Western Power Co. of California, Oakland, Calif.
Peterson, J. R., Western Union Telegraph Co., San Francisco, Calif.
Pettit, Z. T., Los Angeles Gas & Electrical Corp., Los Angeles, Calif.
Phelps, M. W., Pittsburgh Transformer Co., Buffalo, N. Y.
Philipson, R. E., Electric Bond & Share Co., New York, N. Y.
Pimentel, O., Cia Minera San Rafael y Anexas, Pachuca, Hgo., Mex.
Pyle, A. J., Univ of Penna., Philadelphia, Pa.

STUDENTS ENROLLED

Abbott, John N., Univ. of Delaware
Alexander, Philip, Jr., Alabama Poly. Inst.
Anders, Milton, Univ. of Minnesota
Andersen, John A., Brooklyn Poly. Inst.
Archer, George E., Georgia School of Technology
Arima, John K., Univ., of Washington
Baker, Harold D., Drexel Inst.
Baldwin, Rex G., Ohio State Univ.
Barnard, Marill M., Texas A. & M. College
Barrera B., Fernando, Escuela de Ingenieros Mecanicos y Electricistas
Bausman, Willard, Univ. of Southern California
Beckett, W. J. Oklahoma A. & M. College
Bennett, Leon S., Northeastern Univ.
Bickford, Chaloner L., Northeastern Univ.
Biggi, Louis C., Villanova College
Bitter, A. Romeyn, Univ. of Denver
Black, Leonard J., Univ. of California
Blakeslee, Theodore M., Univ. of Southern Calif.
Bohn, Louis G., Jr., Stevens Inst. of Tech.
Bolster, William, Univ. of Washington
Bonanno, Joseph L., Stevens Inst.
Bracken, William W., Washington Univ.
Brandt, Clifford A., Univ. of Minnesota
Brandt, Ralph H., Stanford Univ.
Brookins, Harry, Queens Univ.
Brown, Joseph R., Clarkson College of Tech.
Brown, Richard H., Yale Univ.
Brunner, Harry C., Washington Univ.
Bruzina, Russell, Milwaukee School of Engg.
Buckley, Arthur, Northeastern Univ.
Byrd, Oscar, Univ. of Florida
Campbell, Neil H., Univ. of Southern Calif.
Carlisle, William H., Jr., Mass Inst. of Tech.
Carpenter, Earl, M., Tufts College
Cerveny, Philip F., State College of Washington
Chalmers, Archibald C., Northeastern Univ.
Chrestensen, Carl E., Univ. of Wisconsin
Christison, Donald C., Univ. of Wisconsin
Cifuentes, Joseph, Columbia Univ.
Clark, Fred Stevens, Univ. of Minnesota
Clark, Roy W., Washington State College
Cole, David D., Univ. of Michigan
Collett, Nelson E., Univ. of Calif.
Conners, George W., Jr., Stanford Univ.
Connors, Edward T., Catholic Univ. of America
Corey, Raymond E., Univ. of New Hampshire
Coulson, Arthur G., Univ. of Nebraska
Crabs, Lester J., Oklahoma A. & M. College
Crawford, Duncan A., Mass Inst. of Tech.
Crowley, Homer L., Univ. of Calif.
Davis, Ralph L., Milwaukee School of Engg.
De Jordan, Roy, Univ. of Wisconsin
Dickinson, Raymond L., Yale Univ.
Dodd, Nathan M., Univ. of Nebraska
Dracopoulos, P. T., Yale Univ.
Driscoll, John J., Mass. Inst. of Tech.
Du Bois, J. Harry, Univ. of Minnesota
Dunstan, Gilbert H., Univ. of Southern Calif.
Dyson, Horace R., Mass. Inst., of Tech.
Dytrt, Lumir, Iowa State College
Ellingwood, Mallard E., Northeastern Univ.
Erskine, Arthur J., Univ. of Wisconsin
Farmer, J. Woodruff, Northeastern Univ.
Firestone, Samuel, Univ. of Michigan
Fitz Gerald, Donald D., Yale Univ.
Fitzgerald, Edward P., Johns Hopkins Univ.
Flodin, Carl R., Jr., Univ. of Washington
Frandsen, Dallas J., Univ. of Colorado
Gail, Charles P., Mass. Inst., of Technology
Gast, Raymond W., Stevens Inst. of Tech.
Gilmore, Frank W., Mass. Inst. of Tech.
Gipson, Bernard, Univ. of Southern California
Glenn, Bruce, Oklahoma A. & M. College
Gould, David W., Northeastern Univ.
Graham, Veto J., Univ. of Texas
Gray, Truman S., Univ. of Texas
Grimes, Edgar S., Northeastern Univ.
Grogan, Russell M., Catholic Univ. of America
Gubin, I. Paul, Univ. of Calif.
Gupta, Birjendr N., Mass. Inst. of Technology
Hahn, Paul, College of the City of New York
Halloran, Thomas V., Villanova College
Hampe, George W., Washington Univ.
Hansen, John C., Univ. of Utah
Hardy, Edward J., Case School of Applied Science
Harry, Joseph Paul, Univ. of Southern California
Hawley, Thomas S., Catholic U. of Washington
Hayley, Frank D., Alabama Poly. Inst.
Hemmenway, Donald L., Northeastern Univ.
Hicks, James C., Northeastern Univ.
Hodge, Frederic G., Univ. of Calif.

Weom, L. A., Univ. of Minnesota
Williston, Everett S., Northeastern Univ.
Witts, Seth, N., Univ. of Minnesota
Worden, Arnold W., Northeastern Univ.
Worel, Frank, Univ. of Michigan
Wright, Sherwin H., Univ. of Calif.
Wyeth, Adney, Milwaukee School of Engineering
Zuch, Helmuth W., Univ. of Texas

LIST OF SECTIONS

Name	Chairman	Secretary
Akron	Ralph Higgins	John Grotzinger, 64 Marguerite Ave., Cuyahoga Falls, Ohio
Atlanta	W. E. Gathright	W. F. Oliver, Box 2211, Atlanta, Ga.
Baltimore	W. B. Kouwenhoven	R. T. Greer, Madison St. Building, Baltimore, Md.
Boston	J. W. Kidder	W. H. Colburn, 39 Boylston Street, Boston, Mass.
Chicago	Carl Lee	B. E. Ward, Room 1679, 230 S. Clark St., Chicago, Ill.
Cincinnati	H. C. Blackwell	E. S. Fields, Union Gas & Electric Co., Cincinnati, Ohio
Cleveland	Chester L. Dows	J. F. Schnable, 3503 Mapledale Ave., Cleveland, Ohio
Columbus	R. J. B. Feather	W. T. Schumaker, 25½ North High St., Columbus, Ohio
Connecticut	A. A. Packard	A. E. Knowlton, Dunham Laboratory, Yale University, New Haven, Conn.
Denver	V. L. Board	R. B. Bonney, Telephone Building, P. O. Box 960, Denver, Colo.
Detroit-Ann Arbor	G. B. McCabe	Harold Cole, Detroit Edison Co., 2000 Second Ave., Detroit, Mich.
Erie	H. J. Hansen	L. H. Curtis, General Electric Co., Erie, Pa.
Fort Wayne	E. L. Gaines	D. W. Merchant, General Electric Co., Fort Wayne, Ind.
Indianapolis-Lafayette	H. M. Anthony	J. B. Bailey, 48 Monument Circle, Indianapolis, Ind.
Ithaca	J. G. Pertsch, Jr.	Geo. F. Bason, Cornell University, Ithaca, N. Y.
Kansas City	F. S. Dewey	Henry Nixon, 509 Mutual Building, Kansas City, Mo.
Lehigh Valley	W. H. Lesser	G. W. Brooks, Pennsylvania Power & Light Co., Allentown, Pa.
Los Angeles	R. A. Hopkins	R. E. Cunningham, 1725 Camden Ave., So. Pasadena, Calif.
Lynn	E. D. Dickinson	F. S. Jones, General Electric Co., Lynn, Mass.
Madison	L. E. A. Kelso	Leo J. Peters, University of Wisconsin, Madison, Wis.
Mexico	E. F. Lopez	H. Larralde, Isabel La Catolica, 33 Mexico, D. F., Mexico
Milwaukee	H. R. Huntley	L. F. Seybold, 446 Public Service Building, Milwaukee, Wis.
Minnesota	A. G. Dewars	J. E. Sumpter, 919-23 Security Building, Minneapolis, Minn.
Nebraska		C. W. Minard, 509 Electric Building, Omaha, Neb.
New York	H. A. Kidder	H. V. Bozell, Bonbright & Co., 25 Nassau St., New York, N. Y.
Niagara Frontier	J. Allen Johnson	A. W. Underhill, Jr., 606 Lafayette Building, Buffalo, N. Y.
Oklahoma	E. R. Page	C. C. Stewart, Oklahoma Gas & Elec. Co., Norman, Okla.
Panama	L. W. Parsons	I. F. McIlhenny, Box 413, Balboa Heights, C. Z.
Philadelphia	Nathan Shute	R. H. Silbert, 2301 Market St., Philadelphia, Pa.
Pittsburgh	G. S. Humphrey	W. C. Goodwin, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Pittsfield	E. D. Eby	C. H. Kline, General Electric Co., Pittsfield, Mass.
Portland, Ore.	L. W. Ross	J. C. Henkle, Hawthorne Building, Portland, Ore.
Providence	W. P. Field	F. N. Tompkins, Brown University, Providence, R. I.
Rochester	A. E. Soderholm	Earl C. Karker, Mechanics Institute, Rochester, N. Y.

LIST OF SECTIONS—*Continued*

Name	Chairman	Secretary
St. Louis	Fred D. Lyon	Ralf T. Toensfeldt, 311 City Hall, St. Louis, Mo.
San Francisco	R. C. Powell	A. G. Jones, 807 Rialto Building, San Francisco, Calif.
Saskatchewan	E. W. Bull	W. P. Brattle, Dept. of Telephones, Parliament Bldgs., Regina, Sask.
Schenectady	W. J. Davis, Jr.	W. E. Saupe, Bldg. No. 41, General Electric Co., Schenectady, N. Y.
Seattle	E. A. Loew	C. E. Mong, 505 Telephone Building, Seattle, Wash.
Sharon	W. M. Dann	L. H. Hill, Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Southern Virginia	W. S. Rodman	J. H. Berry, 1338 Rockbridge Ave., Norfolk, Va.
Spokane	G. S. Covey	Richard McKay, Washington Water Power Co., Lincoln & Trent, Spokane, Wash.
Springfield, Mass.	R. P. King	J. Frank Murray, 251 Wilbraham Ave., Springfield, Mass.
Syracuse	W. C. Pearce	L. N. Street, College of Applied Science, Syracuse University, Syracuse, N. Y.
Toledo	A. H. Stebbins	Max Neuber, 1257 Fernwood Ave., Toledo, Ohio
Toronto	L. B. Chubbuck	W. L. Amos, Hydro-Elec. Power Commission, 190 University Ave., Toronto, Ont.
Urbana	C. A. Keener	J. T. Tykociner, 300 Electrical Laboratory, University of Illinois, Urbana, Ill.
Utah	John Salberg	D. L. Brundige, Utah Pr. & Lt. Co., Box 1790, Salt Lake City, Utah.
Vancouver	A. Vilstrup	C. W. Colvin, B. C. Elec. Railway Co., Hastings St., Vancouver, B. C.
Washington, D. C.	A. P. E. Horn	L. E. Reed, Potomac Elec. Pr. Co., 14th & C Sts., N. W., Washington, D. C.
Worcester	E. T. Harrop	Fred B. Crosby, 15 Belmont St., Worcester, Mass.
Total 51		

LIST OF BRANCHES

Name and Location	Chairman	Secretary	Counselor (Member of Faculty)
Alabama Polytechnic Institute, Auburn, Ala	C. W. McMullan	Jas. B. Davis	W. W. Hill
Alabama, University of, University, Ala	C. E. Rankin	Sewell St. John

DIGEST OF CURRENT INDUSTRIAL NEWS

NEW CATALOGUES AND OTHER PUBLICATIONS

Mailed to interested readers by issuing companies

Disconnecting Switches.—Bulletin 25403, 4 pp. Describes the design and engineering specifications of types R and RA disconnecting switches. Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

Ball Bearings.—Booklet F 910, 12 pp., "Precision Ball Bearings for Fractional Horse Power Motors." The Norma-Hoffman Bearings Corporation, Stamford, Conn.

Theatrical Equipment.—Catalog M, 128 pp. Describes a complete line of lighting specialties and lighting effects for the stage, for theatres, motion picture studios, window displays, show rooms, exhibitions, outdoor flood lighting, and many other applications. Kliegl Bros., 321 West 50th Street, New York.

Instruments.—Catalog 8931, 24 pp. Describes various instruments of medium and small size for a number of purposes, including a-c. and d-c. applications in radio work, in checking operation of motor starters and starting controllers, in power plants to check opens and shorts on relay circuits, and many others. Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

Ground Wire Clamps.—Circular describes newly developed ground wire clamp particularly adaptable to "Copperweld" ground rods. The clamps are permanently secured to the ground rods by mechanical means, eliminating the use of soldered connections, although solder may be used, if desired. Exceptional strength is claimed for the new clamp. Copperweld Steel Company, Rankin, Pa.

Power Factor.—Bulletin GEA 232, 32 pp., "Power Factor and Means for Its Improvement." This booklet presents in a simple and systematic manner authoritative information on means for power factor improvement in industrial plants. It is a practical treatise on power factor with the mathematics reduced to simple arithmetic. General Electric Company, Schenectady, N. Y.

Static Condensers.—Bulletin 1670A, 24 pp., "Static Condensers for Power Factor Correction." One section is devoted to a discussion of power factor, its correction and the selection of corrective equipment; another part describes LD static condensers; the third part is devoted to low-voltage static condensers, describing the construction assembly and application. Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

Lighting Data.—A series of bulletins. LD 101B, 28 pp., "Effect of Maintenance and Color of Surroundings on Resultant Illumination;" LD 103C, 36 pp., "The Lighting of Show Windows and Show Cases;" LD 126A, 40 pp., "Lighting for Recreations;" LD 146A, 48 pp., "Stage Lighting;" LD 0A, 16 pp., "Index of Information Contained in Lighting Data Bulletins as of January 1, 1926." Edison Lamp Works of General Electric Company, Harrison, N. J.

NOTES OF THE INDUSTRY

The Sterling Varnish Company, Pittsburgh, Pa., announces that J. S. Applegate, formerly of the Wagner Electric corporation has joined its staff as metallurgical engineer and consultant for users of insulating varnishes.

New G. E. Electric Plant at Los Angeles.—The new General Electric service plant in Los Angeles at 5201 Santa Fe Avenue was formally opened on March 23. This new plant, comprising three buildings, a three-story warehouse, a two-story office building and a service shop, will have a total of 88,000 square feet of floor space.

The American Brown Boveri Electric Corporation, New York, has appointed L. J. Galbreath to take charge of publicity and sales promotion, and as assistant to Earl G. Hines, recently appointed general sales manager. Mr. Galbreath was formerly ted with the Bridgeport Brass Company.

Increased Power Demands in the South.—It has been found necessary to add considerably to the central station facilities this year in several sections of the south. In Florida two new stations have been built totalling 75,000 kw., and in Texas additional turbines totalling 50,000 kw. are being added to the central stations of Dallas and Houston. All the new turbines, three of 25,000 kw. capacity, and two 12,500 kw. units, will be furnished by the General Electric Company.

The Okonite Company, Passaic, N. J., has received an order from the Puget Sound Power & Light Company for 46,800 feet of three-conductor submarine armored cable which will be used to span Puget Sound between Edmonds, on the mainland side, and President's Point, on the Olympic Peninsula, and thus connect the properties which the company recently acquired on the peninsula with the mainland system of interconnected power plants. Two cable connections will be made between the points mentioned and each cable will be capable of furnishing 10,000 h. p. The total weight of the cable will be approximately 750,000 pounds.

Keel Laid of New Electric Passenger Ship.—The keel of the first large electric passenger ship was laid at Newport News, March 20, at the plant of the Newport News Shipbuilding & Dry Dock Company. The vessel, the largest commercial craft built in the United States, will be the first of three sister ships, costing approximately $21,000,000, and will enter the New York California passenger trade in 1927. The new liner will be 601 feet long and will have a speed of 17 knots. Oil burners will furnish steam to two 9000 horse power General Electric turbine generators which will drive the motors connected to the two propellers.

Westinghouse Adds to Mansfield Plant.—A new four-story brick and concrete building with a floor space of 142,600 square feet, has recently been added to the Mansfield plant of the Westinghouse Electric and Manufacturing Company. The new manufacturing unit, which is of the most modern fireproof construction, will be devoted to the construction and assembly of ranges and electric irons. With the addition of this building, the Westinghouse plant at Mansfield has now a total floor space of 330,530 square feet, or seven and a half acres, devoted to the manufacturing of electric ware, hotel appliances, ranges and safety switches.

G. E. Suggestion Awards.—Awards totalling $38,938 were paid 3433 employees of the General Electric Company during 1925 for suggestions made by workers which improved working conditions or tended to increase the efficiency of the company's operations. During the year 11,325 suggestions were offered, of which more than 30 per cent were accepted. During the previous year 12,217 suggestions were made and 26 per cent accepted, and in 1923 but 21 per cent of those offered were accepted. The awards, which ranged up to $500, were paid at the option of the recipient either in cash or G-E Employees Securities Corporation bonds, which yield 8 per cent so long as the original holder remains in the employ of the company.

Foote, Pierson & Company, Inc., New York, manufacturers of photometers and electrical instruments, at a recent annual meeting elected George F. Lewis, president, formerly secretary and treasurer; Malcolm G. Pierson, vice-president and secretary; William R. Stout, assistant secretary and assistant treasurer. Mr. Lewis, a son of Colonel Lewis, inventor of the Lewis machine gun, succeeds Henry G. Pierson, who served as president of the company since its incorporation, and who was made Chairman of the Board. Mr. Lewis was in active service during the war and later he commanded the Engineering Officers Training School at Fort A. A. Humphrey, Va., with the rank of Lieutenant-Colonel. Malcolm G. Pierson is a son of the former president and has been acting as general sales manager. Mr. Stout has been associated with the company for the past twenty years acting as cashier.

Address of Welcome to the I. E. C.*

Once upon a time a Greek philosopher said that to "know thyself" is the first step to wisdom. He might have added that to "know thy neighbour" is the second step to wisdom. I learned this second step when still a boy in my native village.

There are some twelve peasant villages within a circle of a radius of ten miles, of which my native village is the center. Five different races live in these villages: Serbs, Slovaks, Rumanians, Germans, and Hungarians. These simple peasant folk meet each other regularly on market days. Each village has one or two market days during the year, and on such days it is visited by the peasants of the neighboring villages. There the different races meet and greet each other by the Serbian word "komshiya," neighbour. This is the most popular word in their interracial vocabulary. These peasants learn that without the komshiya, the neighbour, one cannot exchange the things which he has for the things that he has not; and above all, one cannot enrich his own experience by the experience of his neighbors. This knowledge is a great help to him who strives to reach that lofty level which is described in the words: "Love thy neighbour as thyself." I do not say that these simple peasant folk in my native district ever reached that lofty level, but I do say that I never saw a small district which looks like glacial moraine of different races where the Serbs, Slovaks, Rumanians, Hungarians, and Germans are so sincerely attached to one another. With them, the difference in breed and creed counts for very little. but identity in the aims of their simple lives counts for very much. This identity of aims acts like a catalyst; it brings their hearts into closer contact and convinces them that they all have the same human hearts and souls in spite of the difference in race and religion.

As I look around this festive board and remember that our beloved guests represent so many different nations and religions I am reminded of my childhood days when I saw my father, an enthusiastic Serb, shaking hands with Hungarians, Slovaks, Germans, and Rumanians from neighboring villages, greeting them with the magic word komshiya, neighbour. I extend to you the same greeting today: Welcome komshiya, welcome our dearly beloved neighbours! Nay, you are even closer to us than neighbours. Do not the names Volt, Ohm, Ampère, Farad, Henry and Gauss; Watt, Coulomb, and Joule, remind us that we all have the same household gods, the same Lares and Penates? And, besides, do we not worship at the altars of the same patron saints: Kelvin, Helmholtz, Maxwell, and Hertz; Siemens, Gramme, and Pacinotti?

We are, indeed, members of the same family, and every meeting of the International Electrotechnical Commission looks more and more like a family reunion. I wish that the Mayor and the Board of Alderman of New York were with us today and that the Congressmen and Senators were with us to study our reunion and learn that scientists and engineers have discovered a secret greater than any secret in science; namely, the secret of laying a true foundation for a League of Nations. Let others follow and the world will soon become a Paradise Regained.

M. I. PUPIN.

*At the Luncheon in honor of the International Electrotechnical Commission, April 14, 1426.

Some Leaders of the A. I. E. E.

PAUL MARTYN LINCOLN, from 1914-1915 twenty-seventh president of the A. I. E. E., was born Jan. 1, 1870 in Norwood, Michigan. In 1880 the family moved to Painsville, Ohio, through the high schools of which town Mr. Lincoln received his early schooling. In 1888, a year in the Western Reserve University, Cleveland, convinced him that his capabilities inclined more to the technical than the classical and upon completion of one year at the Western Reserve University, he entered Ohio State University, from which he received his degree of M. E. in Electrical Engineering June 1892. Immediately upon the close of his final semester, he engaged with the Short Electric Company, of Cleveland, but in December of that year, went to the Westinghouse Electric and Mfg. Co., Pittsburgh, to take up important work for them. Two and a half years later he was chosen electrical superintendent in charge of the water power development of Niagara Falls for the Niagara Falls Power Company. This was the beginning of modern hydroelectric development, and the amount of power generated, transmitted and distributed by this first plant was so far in excess of anything accomplished up to that date as to make it unique, with new problems involved in its progress constantly arising to be solved. In 1902, Mr. Lincoln returned to the Westinghouse Company and for six years was in charge of their Power Division of the Engineering Department. 1910 he was appointed general engineer

for the Company, in which capacity he served until he tendered his resignation in 1919.

From 1911 to 1915, Mr. Lincoln was head of the electrical school at the University of Pittsburgh, still carrying on his work with the Westinghouse Electric & Mfg. Co. while caring for his educational responsibilities. The Lincoln Electric Company had been organized by an older brother in 1894 and it was to join this brother that Mr. Lincoln's resignation was tendered to the Westinghouse Company. He remained with his brother until taking up his duties as director of the School of Electrical Engineering, Cornell University, November 1, 1922.

Beside serving the Institute as its President, Mr. Lincoln was, for five consecutive years, from 1909 to 1914, chairman of its Sections Committee, performing a most efficient service to the professional world in this capacity. The synchroscope, a device now in universal use wherever a-c. machines are parallelled, was one of his inventions for which in 1902 he received the John Scott Medal award from the City of Philadelphia upon the recommendation of the Franklin Institute.

Street Lighting

Street lighting has been a problem ever since men began to herd together in cities. At first the problem was solved by each citizen who ventured out at night carrying a lantern or hiring a link boy to carry a torch before him.

This didn't amount to much as protection from highwaymen, although it did help some in getting over, around, or through the mud puddles. During that period the easiest and most popular solution of the street lighting problem was to stay at home after dark.

By and by came oil lamps, stuck on poles, to help out the hand lanterns. Then gas lamps took the place of oil; and so, by degrees, we come to our modern age of electric lighting.

It is well within the truth to say that, even in America, street lighting is still in a primitive stage. We have of course our "White Way" in every city of any importance, but once outside this area, the streets are often dismal and dangerous after dark. The average community seems to spend just enough on street lighting to make the darkness more confusing. There is a popular notion that street illumination costs much money, but the latest investigation shows that the per capita cost is only about 75 cents a year.

Scientific and adequate street lighting is a social question of paramount importance in the modern world.

First of all we have the fact of vastly accelerated out-of-door movement among all classes of people. Shut in by day, the masses and classes alike are impelled to stir abroad at night. In the threater and shopping district, it has become the recognized practise to make the streets as light as day. What the community fails to furnish, the stores and places of amusement make up as part of their sales and advertising budget.

There are three reasons, among many others, why every city and town and many country roads must from now on be properly lighted.

First, the safety, happiness and comfort of all the people demand it.

Second, the enormous increase in power transportation brings us to the point where traffic growth must cease unless folks can see where they are going. This refers to pedestrians equally with those in automobiles, busses and street cars.

Third, according to an ancient scripture, where the carcass is the birds will gather together. With the streets thronged at night at the centers, it means that the *home* streets, roads and byways will all have belated travellers at night. This brings the hold-up man and other criminals to their harvest. Good street-lighting is second only to a good police force as a crime deterrent. Men love darkness rather than light when their deeds are evil. Crime diminishes as light increases.

Recognizing the great social value of good street-lighting, the scientific and engineering resources of the leading lighting laboratories have been directed towards a solution of this problem with extraordinary success. We have the lamps and the electric energy and we know how to use both to the best advantage in street-lighting. When the people wake up to the necessity of proper street-lighting, half the job will have been done.—*Light*, March, 1926.

Distribution Networks

After much debate the system most favored is the three-phase, four-wire alternating-current network for the supply of light, power or the combination of light and power. But, unfortunately, most services and equipments are 110 volts or 220 volts today, and the electrical relations in the three-phase circuit make it possible only to obtain service at either 115 and 199 volts or 120 and 208 volts with simple transformation ratios. The relative merits of these combinations have been debated thoroughly and especially their effects on service using present standard equipment. No unanimous decision has been reached and both types of networks are in service. Both systems give satisfactory service when standard equipment is used, for, fortunately, lamps may be had at either 115 or 120 volts and single-phase and polyphase motors have tolerances whereby satisfactory operation may be had between, roughly, 110 and 120 volts single-phase and 200 and 240 volts three-phase. But, of course, when operated at points near the tolerance limits the margins of departure from the average motor characteristics are changed, and a design based on either system as a standard would have a wider field of satisfactory application.—*Electrical World*.

Important Features of a Successful Plan for Rural Electrification

BY G. G. POST[1]
Associate, A. I. E. E.

***Synopsis.**—Electric service in rural districts is considered to be a necessity, and a plan for bringing this about in southeastern Wisconsin is outlined in this paper. The main features discussed are: (1) organization for the work, (2) rural rates and financing of line extensions, and (3), advertising and education. A type of economical line construction which will render reliable service is described. The outstanding feature of this line construction is the use of 300-ft. spans. Interesting data, obtained in a survey of a number of rural lines, are presented. The paper shows that in the territory served there were 2740 farms receiving service under the rural rate on January 1, 1926.*

It also shows that the general plan, which has been followed since 1920, encourages the extension of lines and extensive use of the service after farms have been connected.

GENERAL

THE necessity for rural electrification and its economic importance have been widely discussed and there is general agreement that electric service should be made available to our rural population as rapidly as possible. To accomplish results in this direction requires that definite and effective plans be developed and adopted by those electric service supply companies which are in position to serve rural territory.

Plans for bringing about rural electrification vary considerably. Utilities in quite similar territories often differ on important points. Then, there are differences inherent in the territory to be served, such as the density of population and the farming resources, depending in large measure upon productivity of the soil and general knowledge of farming methods. It is not the writer's purpose to discuss or compare various plans but rather to outline a certain plan which has been worked out on a fairly extensive scale and has proved to be effective.

The territory in which these plans are in operation includes 11 counties or portions of counties in eastern and southeastern Wisconsin served by The Milwaukee Electric Railway & Light Company and its associated companies—the Wisconsin Gas and Electric Company and the Badger Public Service Company. Fig. 1 is a general map of the lines of these companies. There is a total of 21,000 farms in the territory.

ORGANIZATION FOR THE WORK

The most essential thing in a rural electrification plan is a proper organization to carry on the work. No company would consider the prosecution of a new and important undertaking without putting some one in charge and making that person responsible for the results.

Rural electrification is a new and important undertaking. It covers a field differing from any that has ever been covered before by electric utilities. If rural electrification is to succeed as fully as it should, the utilities must give it the same careful thought and effort they have given other important activities that have confronted them in the past and that have been successfully handled. The only way to do this is to establish a rural service commercial division, or department composed of a rural agent and such assistants or rural

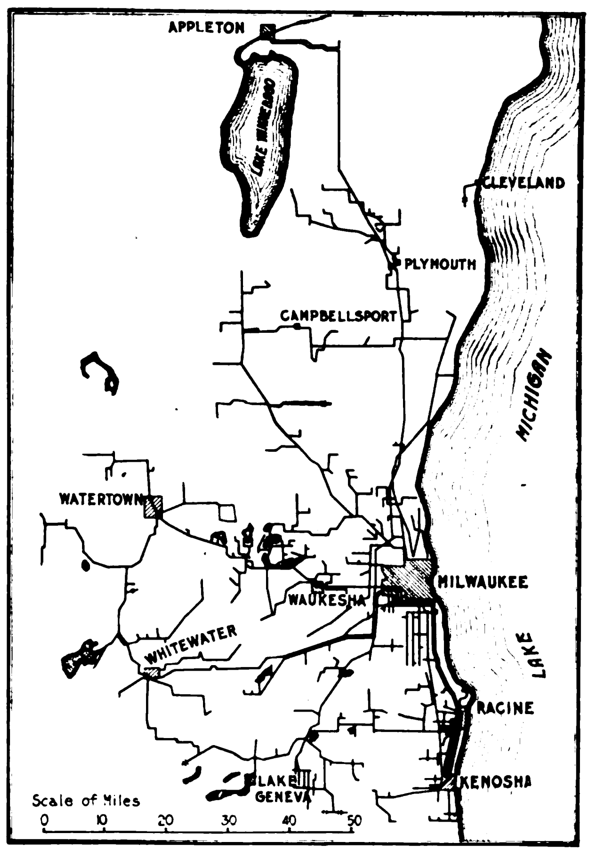

FIG. 1—DISTRIBUTION LINES OF THE MILWAUKEE ELECTRIC RAILWAY AND LIGHT COMPANY AND ASSOCIATED COMPANIES

service salesmen as may be required, to adequately promote the use of electric service and electric equipment by the farmers of the territory the utility serves. The Milwaukee Electric Railway & Light Company employs a rural agent and from four to six rural service salesmen. These men have worked on farms, know the language of the farmer, and at the same time are ex

perienced commercial engineers. They study all phases of the rural electrification problem, take such action as may be necessary to follow up advertising, keep prospective consumers interested in the service, carry on negotiations for line extensions, introduce new uses for the service, and do any other work which the proper conduct of the business requires.

Rural Rates and the Financing of Line Extensions

Before any organization can be effective, a system of rates and a method of financing line extensions, consumers wiring, and equipment must be developed.

It is a sound principle that country dwellers are not much different in their fundamental nature and aspirations than those residing in urban districts and that in establishing rates and line extension policies the same general principles should govern in rural as in urban districts. If it is right and equitable to have the equivalent of a demand charge (active rooms) in residence rates, and if a demand charge in commercial and power rates is right and equitable is it not proper that there should be the equivalent of a demand charge (active rooms and minimum charge per connected h. p.) in the rural rate? Fundamentally, the farm is the farmer's residence and factory and the rate to be equitable must include the characteristics of plain residence rates and those of commercial or power rates. The rate must also be one which will discourage the use of motors of excessive h-p. rating and encourage the consumption of kw-hr. To express it in another way, the rates should encourage the consumer to operate at a high load factor and make the fullest use of the service. With this idea in mind a rural rate, substantially as follows, was developed in 1920:

Rural consumers are defined as consumers generally located outside of the limits of cities and villages who are engaged in farming, stock raising, or dairying.

Rural consumers located upon existing distributing lines or who contribute to the cost of constructing extensions in accordance with the Company's rules and who execute the Company's standard form of rural service contract for a period of not less than two years may purchase single-phase electric service at the following rates.

(*a*) *Service Charge.* Two dollars per month for four or less active rooms plus forty cents per month for each active room in excess of the first four.

Service charge shall include energy consumption equivalent to five kw-hr. per active room per month or not less than 20 kw-hr., in case the active rooms are less than four.

(*b*) *Energy Charge.* Three and one-half cents per kw-hr. for all energy consumed in excess of five kw-hr. per active room, or in excess of 20 kw-hr. in case the active rooms are less than four.

The number of active rooms shall be computed on the following basis:

(1) All rooms contained in the residence shall be counted as active, except bathrooms, basements, garrets, closets, halls, pantry, unwired storage rooms, and three rooms used as bedrooms or sleeping quarters but not used for other purposes.

(2) Rural installations having barns, poultry houses, or greenhouses, but not wired, shall have the residence count increased by one active room.

(3) Rural installations having barns, poultry houses, or greenhouses wired, shall have their counts increased by one active room for each separate horse-barn, dairy-barn, poultry house, and greenhouse actually connected to the distribution system and receiving energy.

(4) Sheds or open barns used to shelter live stock, grains, feeds, or machinery (and not regularly used as horse barns or dairy barns), garages, and miscellaneous buildings, even though wired, shall be exempted from the active room count, excepting such garages, blacksmith shops, and other buildings that may be conducted for and open to the general public as repair or service shops. Each building so conducted shall be counted as an active room.

(5) A barn used as a combination horse and dairy barn shall be counted only as one active room.

(6) Where rural consumers, as herein defined, are located within the limits of cities and villages, such consumers may obtain service on either the rural rate or residence rate applicable in such localities.

The foregoing rate shall apply to all energy used for household purposes, including cooking, and for miscellaneous power purposes, providing the total nominal rated capacity of motors does not exceed three h. p. and providing the motors are not operated between sundown and 11:00 p. m. Service for additional motors will be supplied at the foregoing rates plus an additional charge of fifty cents per month for each h. p. or fraction thereof in excess of three h. p.

The foregoing rate does not include renewals of any incandescent lamps, but is subject to the Company's standard prompt payment discount of five per cent on the first $25.00 and one per cent on amounts in excess of $25.00 on monthly bills paid on or before the last discount date. Bills will be issued as far as practicable 10 days prior to the last discount date.

The gross bills under this schedule may be calculated from the following table.

Monthly Bills for Farm Customers

The minimum charge in this table allows (a) three h. p. in connected motor load and (b) energy consumption of five kw-hr. per active room, or 20 kw-hr. total for less than four rooms.

For connected motor load in excess of three h. p., add 50 cents per month for each h. p. or fraction thereof in excess of three h. p.

For energy consumption, add three and one-half cents for every kw-hr. in excess of five kw-hr. per active room (or 20 kw-hr. total for less than four rooms).

No. of Active Rooms	Kw-Hr. Consumption Allowed on Minimum Charge	Minimum Monthly Charge
4 or less	20	$2.00
5	25	2.40
6	30	2.80
7	35	3.20
8	40	3.60
9	45	4.00
10	50	4.40

As far as the supply company is concerned, there is only one essential difference between rural and urban service, *i. e.*, the greater distances between consumers in the country than in urban territory. This necessitates more line investment per consumer in rural than in urban territory, making it necessary that some means be found for providing for the excess investment.

Before rural service was seriously considered, utility companies found it necessary to devise a plan under which lines could be extended to supply isolated consumers in the fringe surrounding urban territory where the extensions were so long that the revenue would not justify the investment. It became necessary, under such circumstances, for prospective consumers to assist in financing the lines. It was only logical that this principle should be applied in extending lines in rural communities. Consequently the plan was adopted of requiring the prospective consumers to contribute toward the cost of extending the service to them an amount equivalent to the difference between the cost of the extension and the estimated three-years' gross revenue. At the same time provision was made that if other consumers were connected to the extension and it was not necessary for them to contribute toward the cost of their extensions, half of their net bills would be used as a refund to those contributing to the cost of the original extension. Such refunds are discontinued when the original extension has been in service three years, and the total refunds must not exceed the total of the original contributions.

It is usually found that some farmers desire the service more than others, or at least are willing to invest more money in getting it if necessary. Some farmers have been willing to use the service but have been unwilling to contribute anything toward the cost of the line. Others not only are willing to agree to use the service on as extensive a basis as possible, but are willing to contribute a reasonable amount where necessary in order to get the line constructed and the service furnished. It is not possible in these cases to get the farmer consumers on a rural line to bear an equal portion of the investment the company has to make in excess of the amount warranted by the revenue. It has been found necessary to lay the amount to be advanced and the complete proposition, before the group and have them decide among themselves how they will finance the excess cost. One of the farmers, agreeable to both the group and the company, is designated as the official representative of the group and he executes the line extension agreement and turns over to the company the part of the investment required to be advanced by the farmers under the line extension agreement. He may have paid it all himself or he may have collected various parts of it from different farmers. Along with every line-extension agreement there is a blue-print showing the line as constructed and the services connected thereto. This record is carefully preserved and in the future, if there are refunds to the group to be made by the company due to additional consumers coming on the line, they are made to the official representative of the group who executed the line extension agreement and he is responsible for distributing these refunds to the farmers in a manner mutually satisfactory or in accordance with a basis previously agreed upon among themselves.

Although the ownership of lines partially financed by the consumers rests entirely in the utility, the amount contributed is not included in the utility's valuation for rate-making purposes. No special fixed charge is, therefore, included in the rates to cover any extra investment in rural lines and for this reason the monthly charge per kw-hr. is considerably lower than it would be if the utility carried all of the investment.

It must be borne in mind that, ultimately, there will be a vast network of distribution lines serving cities, villages and rural districts alike, and if rural consumers are to remain satisfied there must not be a special fixed charge in their rate to make their cost per kw-hr. higher than that of the urban consumers who may live next to them along the border lines of cities and villages.

Recognizing that it requires a considerable amount of money to contribute toward the cost of lines, to wire farms, and to purchase equipment, a plan has been devised under which the utility advances the money for the purchase of appliances or other equipment and wiring and the rural consumer pays it back on the installment plan in accordance with the terms of certain agreements.

Under the general plan for financing line extensions, farmers are encouraged to install as much equipment as possible so as to increase the gross revenue from the line and cut down the amount which must be contributed toward line extensions. In a good many cases it has been found that this results in the installation of electric ranges or other equipment which would probably not be otherwise installed.

The farmer is thus enabled to make immediate and full use of the service and derive the benefits which electric service always affords.

Advertising and Education

Advertising is just as important in the extension of electric service to the farmers as in any other line of endeavor. The farmer cannot be expected to want it if he is not told about its many benefits. Personal work with the farmers is most effective. The rural agent and his rural service salesmen are most valuable in establishing personal contacts with farmers and acquainting them with all known phases of rural electrification. The efforts of the rural service division are supplemented by the knowledge and experience of the company's regular advertising forces which are especially helpful in advertising in rural papers, in preparing special posters, talking at booster meetings in rural territory, etc. The specific plan adopted is to inform the farmer by all feasible means available as to the special applications and advantages of electric service to each individual farmer. Instead of waiting for the farmers to apply for electric service, the electric service company endeavors to develop the interest of all the farmers in the use of electric service and especially cooperate with those who already have the desire for the service in getting other farmers along the pro-

posed route of the line interested, so that the line may be constructed and the service furnished at the lowest possible cost to any of the farmers. In connection with this work, farmers are being circularized and furnished booklets which show what electric service means to them. Advertisements are being inserted in local newspapers, and demonstrations are being held at various points where an audience of sufficient size to warrant a demonstration and exhibit can be gotten together. At these demonstration meetings well-informed representatives of the company are present, and an effort is made to furnish to the farmers any information desired regarding electric service and electric equipment and how they may be obtained.

The rural service salesmen always stress the point that the utility is not in the business of selling line extensions but rather the service and that it is desirable for the consumer to spend as much as he can afford on equipment which will enable him to make the most use of the service not only in the farm operations but in his home where the convenience of the service is so much appreciated and enjoyed by the housewife.

A roadside sign set up on a farm where a rural line extension is being installed is very helpful in attracting new customers. In some cases, as at the beginning of a line extension where service is available, these signs are illuminated. They are very effective, however, without illumination.

Much effective work is also done by establishing rural electrification booths at state and county fairs. These are strictly educational and informational displays to emphasize to farmers the benefits of the service.

Line Construction

Because of the small number of consumers per mi. of line it is important that the cost of line construction be kept down to the minimum, consistent with reasonable service. This keeps fixed charges within reason and reduces to a minimum the amount which prospective consumers must contribute toward the cost of line extensions.

Utilities should not come to the conclusion that service to farmers can be less reliable than that to the ordinary small city or village. When a farmer installs a range upon which he depends for the cooking of his meals when he installs a milking machine with which he expects to milk the cows, when he installs a heating plant which depends upon electric service for its operation, when he installs a motor-driven pump to furnish water to his stock or for the house, and when he installs other electrically driven equipment upon which his farm processes and operations depend, it is a serious matter if reasonably continuous service is not given and the farmer cannot be expected to electrify his farm if the service is not reliable.

The line construction employed, although it must of necessity be reasonable in cost, must embody all of the features which contribute to make possible safe and continuous operation.

The principal features of the line construction which has been adopted as most reasonable in cost and which at the same time meet the requirements for good service are as follows:

Size of poles	30 ft., 7 in. top, (western red cedar)
Spacing of poles	300 ft.
Size and kind of conductors	No. 2 A. W. G., A. C. S. R.
Size and kind of crossarms	3¼ by 4¼ by 5 ft. 7 in. fir
Size and kind of pins	No. 581 malleable clamp pin (St. Louis Malleable Casting Company)
Insulators	No. 9404 Ohio Brass (or equivalent)
Operating voltage	5000 primary, 120/240 secondary

Every tenth pole an anchor structure.

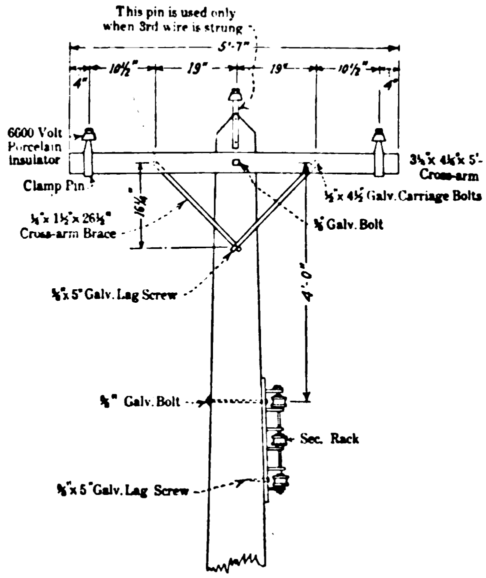

Fig. 2—Arrangement of Pole Top

The details of the construction are shown in Figs. 2, 3, 4, 5, 6, and 7. The cost of a single-phase primary line, exclusive of transformers, lightning arresters, secondary mains, and services is approximately $750 per mi. in country where there is little trouble with trees and where there is neither rock nor too much gravel to interfere with pole setting. If tree conditions are bad or if rock or gravel is encountered, the cost will of necessity be increased. The details of cost are shown in Table I.

That the construction is safe is shown by the following:

Conductor Stresses:

Elastic limit	1860 lb.
Ultimate strength	2660 lb.
Stress at 0 deg. fahr. with ½ in. ice and 8 lb. wind pressure	1860 lb.

Conductor Clearance from Ground:

Clearance at 0 deg. fahr. with ½ in. ice	19.7 ft.
Clearance required by National Electrical Safety Code	18.0 ft.

Resisting Moments of Poles:
Safe loading of 30-ft., 7-in. top western cedar, 30-in. circumference at ground line........... 17,800 ft-lb.
Required by loading ½-in. ice and 8-lb. wind..... 14,870 ft-lb.
Conductor Spacing:
Provided by this construction (three-phase).... 29½ in.
Required by National Electrical Safety Code for 300-ft. spans............................ 18¾ in.
Pins and Insulators:
Lateral stress with ½ in. ice and 8-lb. wind pressure.................................. 263 lb.
Stress in direction of line (conductors broken)... 1860 lb.
Stress which two pins on anchor structure will safely withstand........................ 1950 lb.
Stress which insulators will withstand.......... 4000 lb.
Crossarms:
Stress in direction of line which single arms will safely withstand........................ 1880 lb.
Stress in direction of line (maximum loading) one conductor broken........................ 1860 lb.

TABLE I
ESTIMATED COST PER MILE FOR THE EXTENSION OF TWO NO. 2 A. C. S. R. USING 300 FOOT SPANS

Material	Unit Cost	Quantity	Amount
No. 2 A. C. S. R.	$0.0208	10,700 ft.	$222.56
5/16 in. guy wire	0.018	440 ft.	7.92
30 ft. western cedar poles	7.14	18	128.52
35 ft. western cedar poles	11.92	2	23.84
Everstick Anchors	1.52	4	6.08
No. 4 X insulators	0.27	8	2.16
Pole shims (large)	0.12	16	1.92
2 bolt guy clamps	0.42	32	13.44
5 ft. 7 in. cross-arms	0.69	20	13.80
Cross-arm braces	0.24	32	7.68
No. 581 clamp pins	0.457	40	18.28
5/8 by 12 in. galvanized machine bolts	0.083	16	1.33
5/8 by 16 in. galvanized machine bolts	0.105	2	0.21
5/8 by 5 in. galvanized lag bolts	0.0411	16	0.66
1-1/2 by 4-1/2 in. galvanized carriage bolts	0.0315	32	1.01
6600 volt pin type insulators	0.14	40	5.60
Aluminum sleeves (2 sleeves per joint)	0.16	4	0.64
Aluminum armor for insulator ties	0.35	2.9 lb.	1.02
No. 6 tie wire (annealed aluminum)	0.33	3.0 lb.	.99
Total Material			457.66
Labor			
Pole crew	5.94	12 hrs.	71.42
Line crew	3.75	16 hrs.	60.04
Supervision and engineering			19.72
			151.18
Sundries			
Truck	0.65	28 hrs.	18.20
Tools and injuries—5 per cent of labor			7.43
Right-of-way			54.08
			79.71
Contingencies			
Grand Total			58.35
			$746.90

Note: Pole Work—1 foreman, 1 driver and 6 polemen can set 12 poles per day of 8 hr.
Line Work—1 foreman, 2 linemen and 2 groundmen can install cross-arms, string wire and tie in 1 mi. in 2 days of 8 hr. each.

Where secondary mains are necessary, 30 ft., 6 in., top poles spaced 150 ft. apart are used except for transformer poles which must have not less than 7 in. tops. This permits the use of No. 6 or larger, hard-drawn copper secondary mains installed on racks. All transformer connections are of copper and the copper conductors are connected to the aluminum conductors with approved clamps.

Results Achieved

During the fall and winter of 1925-1926 some interesting data were collected on a few rural lines.

Month and kw-hr. of minimum use of energy—Average per customer	91 Mar.	32 Sept.	28 Apr.	78 Mar.		69 Mar.*†

*Weighted averages.

†New line. Kw-hr. figures not available or considered in determining weighted averages.

1. Transformer demand factors are the ratios obtained by dividing the maximum 15-min. transformer demands by the total transformer connected loads.

2. Line demand factors are the ratios obtained by dividing the maximum 15-min. line demands by the total connected loads on the line.

3. Diversity factors of line and transformers are the ratios obtained by dividing the maximum 15-min. line demand by the sum of the individual maximum 15-min. transformer demands.

4. Per cent losses are based upon the difference between measured kw-hr. line input and kw-hr. recorded on customers meters over an extended period of time.

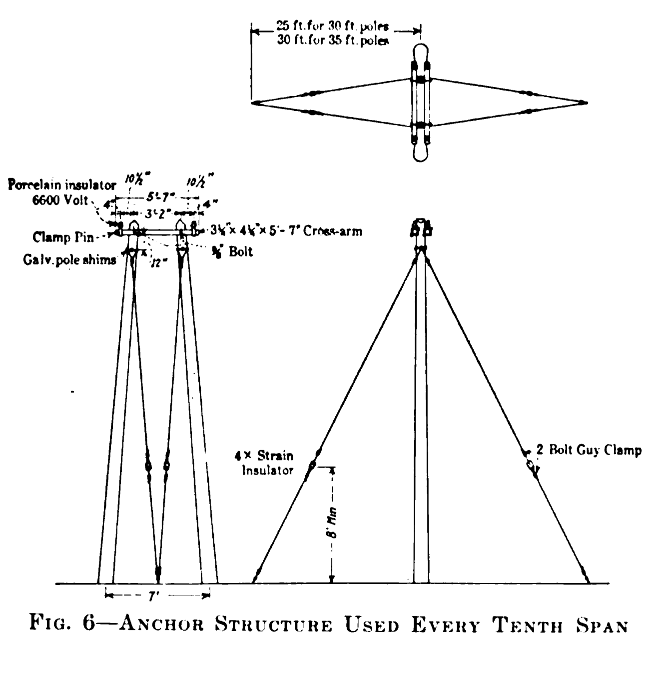

FIG. 6—ANCHOR STRUCTURE USED EVERY TENTH SPAN

These data are shown in Table II. It is interesting to observe that in general more load was found connected than the farmers agreed to connect when contracting to take the service. While the average contracted for was 5.59 kw., the average found connected was 6.88 kw.

Another fact of interest is that the transformer loading was found to be low. It is known from individual consumers' records that the maximum consumption is very apt not to occur in the winter, when these data were taken. This may be partly due to the fact that in the summer the farmer uses his electric range while in the winter he uses a wood range. He also does more pumping in the summer and carries on other operations more extensively. Comparable data taken during the summer months will show whether transformers larger than necessary have been furnished or not.

The power factor at time of maximum load was found to vary from 89 per cent to 97 per cent on the various lines tested. Annual kw-hr. per consumer on the vari-

ous lines averaged from 640 to 1694. Line, transformer, and meter losses were found to vary from 19.5 per cent to 37.4 per cent.

Fig. 8 shows the number of consumers served under the rural rate by years from 1920, when the rate was adopted, to January 1, 1926, when there were 2740 rural consumers connected.

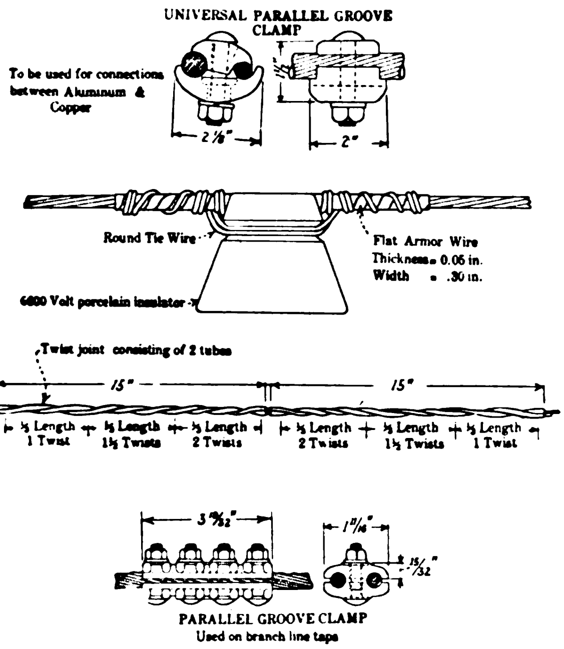

Fig. 7—Clamps, Splice and Tie

Conclusion

Utility companies must view the rural business broadmindedly and provide a reasonable line extension plan, and rate schedule which will encourage the use of the service. A rate schedule designed to pay full returns on investment from the very start, by using burdensome minimum charges or high rates per kw-hr., will produce the opposite result.

A financing arrangement has been found to be necessary, because a rural line extension project involves a number of farmers, all of whom must arrive at the buying point at one time. Where the farmers' activities are somewhat varied, all may not have the funds available at the time the project is developed to the final stage. If it cannot be concluded then but has to be postponed because some do not have the funds available, when it is reopened, some of the others may not have the funds available, and often a project is delayed for an indefinite period of perhaps a year or two. A farmer who can afford to go into such a project at all will have the funds available at sometime within a year. A plan whereby his financial obligations can be taken care of satisfactorily until such time as he has the funds available leaves no obstacle in the way of concluding the negotiations when all agree upon terms.

Experience has demonstrated that the all important thing in general rural electrification is to make the service available to the farmers. The records show that as soon as the service is available the farmers will find new and increasing ways of utilizing it as industries in the urban centers have done and are continuing to do. Every farm can be made a laboratory in a greater or lesser degree for carrying on experimental work, and the greater the number of farms carrying on such work, the greater will be the increase of new applications for the service. It is important, therefore, for utilities to cover their rural territories as quickly as possible with suitable supply lines. This can be done with reasonable assurance that load not contemplated now will develop as new uses for the service are found and as the people come to realize, as they can only through use and reasonable encouragement on the part of the utility, its many and varied advantages.

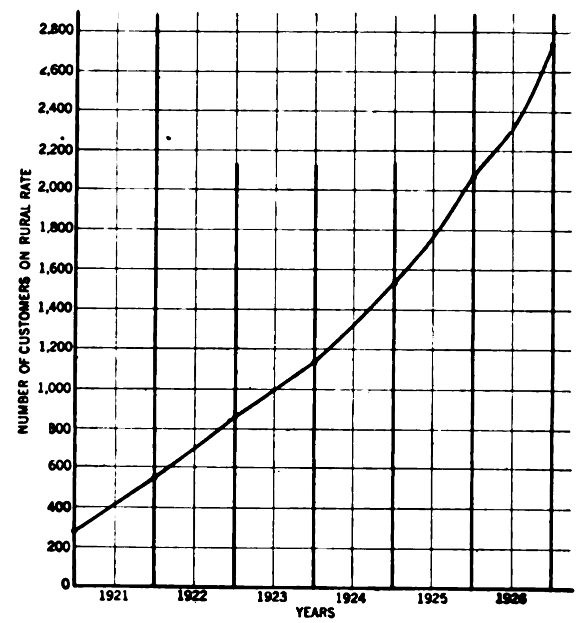

Fig. 8—Number of Rural Customers on Line of the Milwaukee Electric Railway and Light Company and Associated Companies by Years

ELECTRIC "EYE" SORTS CIGARS

A cigar sorting machine has been perfected for use by cigar manufacturers, which has proved exceptionally accurate and speedy in its work. Cigars are sorted according to the shade of their coloring into no less than thirty separate grades, and to do this successfully requires, in a human, an exceptionally well trained eye. Recently an electrically operated machine has been developed for this purpose which will do this work with greater speed and accuracy. As this device automatically picks up each cigar and holds it up to its "eye," a photoelectric cell, the various shades of brown cause varying reactions in the photoelectric cell, and relays actuated by these different currents select the compartment in which the cigar belongs. The machine grades sixty cigars every minute.

A Contribution to Research on the Experimental Determination of the Losses in Alternators

BY EDOUARD ROTH[1]
Associate, A. I. E. E.

Synopsis.—In this paper the author deals with one of the questions with which the International Electrotechnical Commission is at present occupied; namely, the determination by simple tests of the actual losses in alternators. The author first reviews the existing rules and then states the variation of the losses in alternators as a function of the load and as a function of the power factor. His paper contains records of experimental researches which he has made and which serve on the one hand as a basis for discussion of the theoretical considerations which he develops and on the other hand to compare the actual losses with those obtained by the methods given in the rules at present in force. The author does not present definite conclusions since, in his opinion, these investigations ought to form the basis for a program of future researches and ought to serve as the basis for discussions in the Rating Committee of the International Electrotechnical Commission.

* * * * *

Introduction

The separate loss method is still often considered as sufficient for the experimental determination of the efficiency of electric machines. In this method a no-load test at the normal voltage gives the mechanical losses, friction and windage losses, as well as the core or magnetic losses. The electrical losses due to the current in the armature and the excitation circuit are calculated on the basis of the resistances, when hot, of the various circuits and the currents in these circuits. This method gives, of course, good results in the case of small machines and it is not desired to supersede it, but in the case of large machines, and especially in large alternators it gives absolutely incorrect results. In fact, this method does not take into account either the actual electrical losses, or the fact that the iron losses correspond to an internal voltage higher than that at the terminals, and it totally excludes the phenomena by which the no-load conditions differ from the conditions under load. In short, it neglects the stray load-losses.

Therefore, the modern tendency is to investigate methods by which, with simple tests, the actual losses in the machines may be determined with great accuracy when carrying full load.

The American Institute of Electrical Engineers was the first of the electrical associations in any of the various countries to establish elaborate rules on this subject.

In what follows the excitation loss will not be taken into consideration since this can be determined with sufficient accuracy by simple tests. In fact, rules established by these associations give methods which make it possible to calculate the exciting current on load from the no-load and the short-circuit characteristics. Besides, it is always possible to get the exact value of the excitation loss by a test on load. It is much more difficult to determine the magnetic loss and particularly the electric loss in the armature.

1. Engineer-in-Chief, Société Alsacienne de Constructions, Mécaniques, Belfort, France.

Presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

With regard to core loss, the Standards of the A. I. E. E. (1925 revision) read as follows:

"7-468 Core losses.—Drive the machine from an independent motor, the output of which shall be suitably determined. The brushes shall be in contact, and the machine shall be excited, so as to produce at the terminals a voltage corresponding to the calculated internal voltage for the load under consideration. The difference between the output obtained by this test and that obtained by test under paragraph 7-467 shall be taken as the core loss.

The internal voltage of synchronous machines shall be determined by correcting the terminal voltage for the resistance drop only."

To determine the losses on load, these Standards propose to augment the core losses by the stray load-losses. In regard to the stray load-losses they read as follows:

"7-470 Stray Load Losses.—These include iron losses, and eddy-current losses in the copper, due to fluxes varying with load and also to saturation.

Stray load-losses shall be determined by operating the machine on short-circuit and at rated-load current. This, after deducting the windage and friction and $I^2 R$ loss, gives the stray load-loss for polyphase generators and motors."

This method of obtaining the stray load-losses from the short-circuit tests has likewise been adopted in France. However, the following method may also be used alternatively:

"With the rotor removed and the stator winding carrying normal current at rated frequency, the power input is measured.

This value, after deduction of the $I^2 R$ losses, represents the supplementary losses."

Several comments will be made on these rules: First, it is easy to see that the geometrical addition of the ohmic drop to the normal voltage has no influence whatever on the value of the iron loss to be introduced in the calculation of the efficiency. However, this rule shows that a certain correction should be made to the normal voltage to account for the actual core loss on

load. One of the main objects of this study is to determine the precise amount of this correction.

Then, with regard to losses other than the core loss, that shall be accounted for on load, two questions should be answered; first, do the two tests give the same result and second, in what proportion is this result to the actual losses.

It is well known that in turbo alternators or in general, in high armature reaction alternators, the *short-circuit losses* measured are very much too high; the tests reported hereafter were made to determine whether or not this is the case with salient pole alternators of small size and small armature reaction. It is essential to know the value of the armature reaction in determining the accuracy of the short-circuit test as a method of measuring the stray load-loss. Several authors[2] have already given reasons for this experimental feature in the case of turbo alternators, and it is needless to go into them here. However, these reasons cannot be applied to salient pole alternators; but contrary to what is generally admitted, it seems that the iron loss on short circuit cannot be neglected

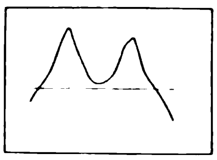

FIG. 1—FIELD CURVE ON SHORT-CIRCUIT

on account of the well-known shape of the field curve. See Fig. 1 as an example of such curves.

On the contrary, the results of the test with *rotor removed* seem to be nearer actual conditions, even in the turbo alternators. One objection to this test is that it is carried out with a very low power factor which implies a lack of accuracy in the readings of the wattmeters, especially if current transformers are used.

Reviewing the situation it may be stated that the core loss determined according to the A. I. E. E. Standards is certainly too small, while the electrical losses resulting from the short-circuit test are often too large. However, it may be possible, as already expressed at the Hague, that the sum of these two indications is sufficiently close to the actual value of the losses on load. In the event that this could be proved for a sufficient number of very different machines, the prescribed rules of the Standards would hold good.

We trust that the tests reported hereafter will shed some light on these various questions. These tests have been carried out at the works of the Société Alsacienne de Constructions Mécaniques, at Belfort. These measurements are very delicate, and in order that definite conclusions be reached other manufacturers should make similar tests. We consider the present study more as a basis for discussion and as a program for further investigations.

Definitions. As in the plain separate loss test the losses will still be segregated into mechanical, magnetic and electric. No special comment is necessary with regard to the first; these include the sum P_0 of the friction losses in the bearings, the friction losses of the brushes, etc., as well as the windage and the ventilation losses. By *magnetic* losses is meant those due to flux. These are developed principally in the active iron, however, they can develop elsewhere. They include, for example, the losses at the surface of the pole pieces, those in the fastening bolts and in the end-bells or end-plates, where they are generated by the leakage flux of the inductor. They vary with the load and are in consequence a function of both the current I and the voltage U. By *electric* losses are meant the losses proportional to the square of the current. They appear not only in the copper of the armature but in every part of the machine where currents are induced by the main current, such as end-bells, end-plates, dampers, etc.

Neglecting, as stated above, the excitation loss in the machine, the total losses, P, can be represented by the following equation:

$$P = P_0 + f(U, I) + a I^2 \qquad (1)$$

The above definitions do not mention the stray load losses as these are included either in the magnetic or electric losses.

Electric losses. The coefficient a in the expression $a I^2$ is equal to the resistance r of the winding, multiplied by a factor k greater than unity.

$$a = k r$$

It should be noted here that the electric losses are not necessarily proportional to the square of the current. When the solid parts subjected to the induced currents become saturated by flux, it may happen that some of these terms vary according to another law. But, as stated above, we will neglect such variation and assume the law of the square.

In what follows we will assume that for a given temperature of the machine and consequently for a well determined value, r, of the resistance, the value of k is independent of the value of the current and of its phase angle.

Variation of the magnetic loss with the load. Curve I of Fig. 2 represents the no-load losses of an alternator running as a synchronous motor at no-load, with minimum current. This curve we shall call the "no-load loss characteristic." It is desired to find on this curve the value of the virtual internal voltage corresponding

to the magnetic loss on load, for a given current and a given phase angle, which voltage we will call the "magnetic loss voltage."

Let $O\,A$ (Fig. 3) represent the normal voltage U_0 at the terminals, or else the flux in the machines; add geometrically to $O\,A$ the ohmic drop $A\,B = k\,r\,I$, also the inductive drop $D\,B = x\,I$, due to the leakage flux, to obtain the total electromotive force $O\,D$ (or $O\,D'$ in the case of a leading angle of phase when running as a generator).

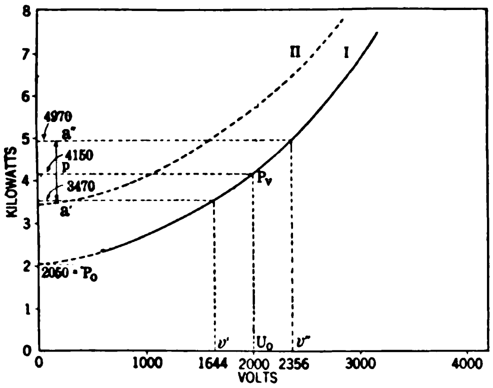

Fig. 2—Characteristics of Core Losses

It would be very simple, as it has been proposed, to adopt for the value of the magnetic loss voltage that corresponding to the vector $O\,D$, as the inductive drop $B\,D$ due to leakage can be measured with sufficient accuracy without difficulty.[3]

This method has already been proposed at the Hague and it may be possible that the results of the studies now in progress will lead to its insertion in the rules.

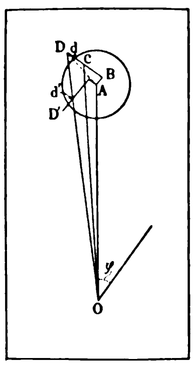

Fig. 3

However, there are several reasons why the voltage $O\,D$ does not represent the magnetic loss voltage.

First, the inductive drop $B\,D$ due to the leakage is composed of two parts: the one $B\,C$ corresponding to the leakage in the end turns of the coils, the other $C\,D$, due to the leakage in the slots. But the flux in the core is only $O\,C$, so that taking the voltage $O\,D$ as the magnetic loss voltage will, therefore, give too high values.

Further, the leakage flux in the slots tends to saturate the teeth which separate the slots belonging to two different phases when the alternator runs on a capacitive load, and tends to weaken the flux in the teeth when it runs on an inductive load, which increases the losses in the first case and reduces them in the second.[4]

Obviously, it may be inferred that it would not be correct to add vectorially the total inductive drop $B\,D$ to obtain the magnetic loss voltage; it seems that a virtual inductive drop $x_p\,I = D\,d$ should be added, (less than $B\,D$), to obtain this voltage. Running with a lagging phase angle, the losses would be smaller than those corresponding to the inductive drop $O\,D$; while with a leading angle of phase they would be higher since $O\,d'$ is greater, in that case, than $O\,D'$.

But a very important experimental fact invalidates these conclusions in great proportion. It is known that the field curve along the surface of the poles of salient-pole alternators varies considerably with the phase angle of the current.

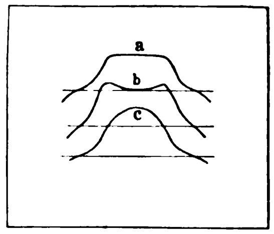

Fig. 4—Field Curves of Alternator
a. No load b. Lagging c. Leading

This curve inflects with lagging armature current (field over-excited) and swells, becoming nearly a sine wave with leading current (field under-excited).

Fig. 4 is an example of such curves. Fig. 4A represents a field curve at no-load and Figs. 4B and 4C correspond to lagging and leading phase angles respectively. But the curves of the type of Fig. 4B give higher losses than those of the shape of Fig. 4C; this is proved theoretically and confirmed by tests. Thus the points d and d' draw nearer again to D and D^1. See Fig. 3. It is proposed to precisely determine, by suitable tests, whether, and by how much, the virtual inductive drop $B\,d = x_p\,I$, which we call the "inductive drop of loss" differs from the inductive drop of leakage $B\,D$.

Owing to the secondary phenomena we have just mentioned there is nothing to indicate that the reactance of loss, x_p, is independent of the phase angle for a given current. However, in the following developments we will assume that the reactance x_p is constant. On this assumption, the current being constant, when the phase angle varies, the point d describes a circle around A

3. E. Roth, "Critique de quelques méthodes de mesure de la resistance due aux fuites de l'induit des machines électriques rotatives a courants alternatifs." *Revue Générale de l'Electricité* du 7 Juin 1925, XVII, p. 217.

4. E. Roth, "Les pertes supplementaires dans les machines electriques," *Bulletin de la Société Francaise des Electriciens*, 1925, p. 495.

as a center, with $A\,d$ as a radius. This assumption as well as that of the constancy of the factor k shall be justified by tests.

Determination of the constants k and x_p from measurements of the losses, the machine being run as a synchronous motor at no-load, with variable current:[5] It is possible to run an alternator approximating normal conditions at no load as a synchronous motor, either over-excited or under-excited at nearly zero power factor, the current being the same in each case. The power input in these two tests represents the losses, and will not only give the reactance of loss x_p and consequently the magnetic loss, but also the electric losses and, therefore, the factor k.

The conclusions that can be drawn from these tests amply justify the assumptions, for these are the limiting values of the secondary phenomena and particularly of the variation of the shape of the field curve.

In fact, for the over-excited conditions, the total losses P'' may be expressed for a three-phase alternator by

$$P'' = P_0 + 3\,k\,r\,I^2 + f\,(U'') \tag{2}$$

r being the resistance per phase. U'' is the loss voltage corresponding to these running conditions (Fig. 2) and as shown in Fig. 5 is approximately:

$$U'' = O\,N'' = U_0 + x_p\,I\,\sqrt{3} \tag{3}$$

x_p being the reactance of loss per phase.

Similarly, in the under-excited conditions:

$$P' = P_0 + 3\,k\,r\,I^2 + f\,(U') \tag{4}$$

where

$$U' = O\,N' = U_0 - x_p\,I\,\sqrt{3} \tag{3 a}$$

Subtracting (4) from (2)

$$p = P'' - P' = f\,(U'') - f\,(U') \tag{5}$$
$$= a'' - a' \text{ taken on Fig. 2.}$$

The question is then to obtain by successive approximations, which are easily made, two values of U' and U'', symmetrical with regard to U_0, and such that the difference of the losses measured on the loss characteristic (Fig. 2) is equal to p.

Then:

$$x_p = \frac{U'' - U_0}{I\,\sqrt{3}} = \frac{U_0 - U'}{I\,\sqrt{3}} \tag{6}$$

Substituting this value of x_p in equation (3) gives U'', and this, when substituted in equation (2) determines $K\,r$. Now, since r is known, K is obtained.

Knowing the values of k and x_p, the loss at any load may be calculated. The magnetic loss voltage $O\,M$ for any running condition may be determined from the diagram of Fig. 5; and knowing this, the magnetic losses may be obtained from the loss curve, to which the $k\,r\,I^2$ losses are to be added and also the mechanical losses P_0.

5. In other words, readings of the power input are taken when the alternator is run as a synchronous motor for the V-curve test.

It is to be noted that this method, as in the case with the rotor removed, involves the disadvantage of being carried out at a low power factor. However, with certain precautions, this method can be carried out successfully, as the following tests indicate. If wattmeters gave correct readings at low power factor, this method could be extended to the calculation of the losses in any running condition, provided, of course, that the above assumptions be justified by tests.

Study of the curve of the losses as a function of current when running as a synchronous motor at no-load. The above assumptions could first be checked in the following manner: Simultaneously with the readings for the V curve, readings of the corresponding losses are taken, and then a curve of these losses is drawn in terms of the current. We have called this a comet curve because of its special shape. Readings of the losses are then taken for the same current I_1 on the two branches of the curve, corresponding to which, values of x_p and k are deducted according to the above method and from these values the comet curve is plotted. The

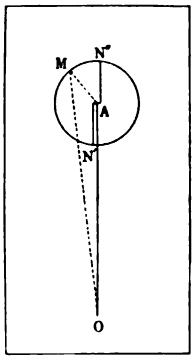

Fig. 5

coincidence of the calculated curve and that obtained from test will justify the assumptions.

This calculation is possible only when the equation of the no-load-loss characteristic is known. It is particularly simple in non-saturated machines where this curve is a quadratic parabola.

In this case it is possible to avoid the cut-and-try method by solving equation (5); $f\,(U)$ is then of the form, $\frac{U^2}{\rho}$. The analytical solution is given by the equation:

$$p = \frac{U''^2}{\rho} - \frac{U'^2}{\rho} \tag{7}$$

since:

$$(U''^2 - U'^2) = (U'' - U')\,(U'' + U')$$
$$U' + U'' = 2\,U_0 \tag{8a}$$
$$U'' - U' = 2\,x_p\,I_1\,\sqrt{3} \tag{8b}$$

Thence:

$$p = \frac{(U'' + U')\,(U'' - U')}{\rho} = \frac{4\,U_0\,x_p\,I_1\,\sqrt{3}}{\rho}$$

which gives:

$$x_p = \frac{p\,\rho}{4\,U_0\,I_1\,\sqrt{3}} \tag{9}$$

ρ can then be determined by setting up the following expression for the losses corresponding to the voltage U_0—see Fig. 2.

$$\frac{U_0^2}{\rho} = P_v - P_0 \text{ and } \rho = \frac{U_0^2}{P_v - P_0}$$

k is then deducted and thus it is possible to calculate the electric losses and to plot the comet curve for the various values of the current.

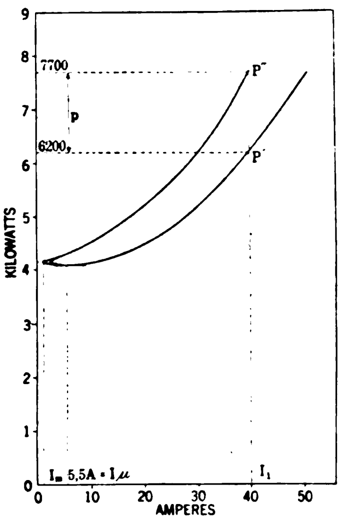

FIG. 6—COMET CURVE

Were it possible to assume the no-load loss characteristic to be a parabola of the second order, the above mentioned method could be employed to give a first approximation of the value of x_p, later to be revised by a cut-and-try process.

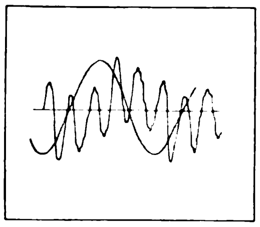

FIG. 7

Formulas (**8a**) and (**8b**), and the conclusions drawn therefrom, have been based on the assumption of zero power factor. This condition is fulfilled even for small values of current, and it is only for currents near the minimum of the V curve that the method indicated fails.

If it is assumed that the no-load-loss curve is a quadratic parabola, it is possible to calculate the comet curve for the exact value of the angle of phase; however, to give this study a practical instead of a theoretical aspect, we will not present this development here. The curve of Fig. 6 has thus been calculated, and for the current I, the corresponding losses are P'' and P'.

Even when variable power factor is taken into account near minimum current, the points of the comet curve do not correspond with those of the curve obtained from the tests. It is known that the wave form of minimum current of a synchronous motor is very distorted (Fig. 7). The minimum current read will be higher than that corresponding to the voltage and the power. This explains why the test results give the dotted part of the comet curve shown in Fig. 6.

The comet curve has a peculiar characteristic which may appear paradoxical at first. This feature is of no practical interest. However, it may confirm our hypothesis. It will be noticed on Fig. 6 that the minimum loss does not correspond to the minimum current. The losses decrease in a certain part of the curve when the current increases. This minimum loss occurs when the conditions are such that the increase of the electrical losses $k\,r\,I^2$ is less important than the corresponding decrease of the magnetic loss. Hence, this minimum occurs for a certain ratio between x_p and $k\,r$.

The existence of this minimum is easily explained analytically in the simple case of the quadratic parabola. Since this minimum can only occur in under-excited conditions, formula (4) reads as follows:

$$P' = P_0 + k\,r\,I^2 + \frac{(U_0 - x_p\,I\,\sqrt{3})^2}{\rho}$$

which gives:

$$p' = \left(P_0 + \frac{U_0^2}{\rho}\right) - \frac{2\,x_p\,U_0\,\sqrt{3}}{\rho}\,I + 3\left(\frac{x_p^2}{\rho} + k\,r\right) I^2$$

as the equation of the lower branch of the comet curve, on the assumption of zero power factor, which as stated, is permissible, even for small values of current.

This parabola gives a minimum corresponding to a current:

$$I_u = \frac{U_0}{\sqrt{3}}\;\frac{x_p}{(x_p^2 + k\,r\,\rho)} \tag{12}$$

and a power:

$$P_u = \left(P_0 + \frac{U_0^2}{\rho}\right) - \left\{\frac{U_0^2}{\rho}\right\}\left\{\frac{x_p}{x_p^2 + k\,r\,\rho}\right\} \tag{13}$$

$$P_u = \left(P_0 + \frac{U_0^2}{\rho}\right) - \frac{x_p}{\rho}\,U_0\,I_u\,\sqrt{3}$$

which, remembering that the term $P_0 + \dfrac{U_0^2}{\rho}$ represents the no-load loss P_v at the pressure U_0, therefore, can be written

$$P_u = P_v - \frac{x_p}{\rho}\,U_0\,I_u\,\sqrt{3} \tag{13a}$$

This minimum power has no physical existence unless the value of the minimum current I_m taken by the

motor be less than the current I_u corresponding to the minimum of the losses

$$I_m < I_u \qquad (14)$$

It can be shown that this corresponds to the condition

$$\frac{P_v}{P_v - P_0} k r < x_p \qquad (15)$$

or

$$\frac{\text{Total no-load losses}}{\text{No-load core losses}} k r < x_p$$

Experimental researches. A series of tests have been carried out on a 320 kv-a. 3000-volt, 61.6-ampere, 50-cycle, 26-pole synchronous motor. The results of these tests have been translated into the curves of Figs. 1, 2, 4, 6 and 8. The comet curve of Fig. 6 and the field curve of Fig. 4 have not been obtained at the normal voltage of 3000 but at 2000 volts, as the no-load loss characteristic at the latter voltage very nearly follows the law of the square, and also because the

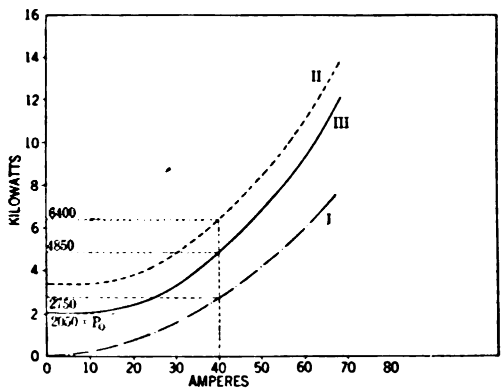

FIG. 8—CHARACTERISTICS OF ELECTRICAL LOSSES
I—Losses, measured, rotor removed
II—Short circuit losses

differences in the field curves are more pronounced when the alternator is not saturated.

As already explained, this characteristic has been obtained from the value of the power input with the machine running as a synchronous motor, at no-load and at the minimum current. The motor became unstable below 620 volts. Therefore, the dotted part of the curve had to be assumed in order to determine the mechanical losses; $P_0 = 2050$ watts. The total losses P_v on no-load at $U_0 = 2000$ volts are 4150 watts, which gives as the iron loss $4150 - 2050 = 2100$ watts.

ρ will be obtained from

$$2100 = \frac{2000^2}{\rho}$$

thence, $\rho = 1905$ ohms.

The iron losses at 2356 volts and 1644 volts are:
$4970 - 2050 = 2920$ watts and
$3470 - 2050 = 1420$ watts, respectively.

In order to determine whether the law of the square is satisfied, at 2356 volts we find

$$\frac{2356^2}{1905} = 2905 \text{ watts against } 2920 \text{ watts;}$$

and at 1644 volts

$$\frac{1644^2}{1905} = 1418 \text{ watts against } 1420 \text{ watts}$$

These results are practically identical. At 3000 volts, on the contrary, the curve considerably deviates from the quadratic parabola.

Let us now refer to the comet curve of Fig. 6. With the alternator running at no load as an over-excited synchronous motor, and carrying an armature current of 40 amperes, the power input was 7700 watts as compared with 6200 watts for the under-excited conditions.

Then $p = P'' - P' = 7700 - 6200 = 1500$ watts

Formula 9 gives for the reactance of loss,

$$x_p = \frac{p\,\rho}{4\,U_0 I_1 \sqrt{3}} = \frac{1500 \times 1905}{4 \times 2000 \times 40 \sqrt{3}} = 5.14 \text{ ohms.}$$

and for the inductive drop of loss,

$$x_p I_1 \sqrt{3} = 5.14 \times 40 \sqrt{3} = 356 \text{ volts}$$

The loss voltages are respectively:

$$U'' = U_0 + x_p I_1 \sqrt{3} = 2000 + 356 = 2356 \text{ volts}$$

$$U' = U_0 - x_p I_1 \sqrt{3} = 2000 - 356 = 1644 \text{ volts}$$

Equation (2)

$P'' = P_0 + f(U'') + 3 k r I^2$ becomes

$$7700 = 4970 + 3 k r I^2$$

Whence $3 k r I^2 = 2730$ watts.

The resistance r per phase is

$$r = 0.52 \text{ ohms}$$

which gives

$$k = \frac{2730}{3 \times 0.52 \times 40^2} = 1.094$$

or $k r = 0.569$ ohms

Thus, we know all the data required for the calculation of the comet curve. This has been traced on Fig. 6 and practically coincides with the curve obtained from the tests. The coincidence is particularly marked for the minimum P_u of the losses. The existence of this minimum is evidenced by the verification of the following inequality:

$$\frac{\text{Total no-load losses}}{\text{No-load iron losses}} k r < x_p$$

which gives in our case;

$$\frac{4150}{2100} \times 0.569 < 5.14$$
$$1.13 < 5.14$$

The corresponding current I_u for minimum input is, according to (12)

$$I_u = \frac{U_0}{\sqrt{3}} \times \frac{x_p}{x_p^2 + k\, r\, \rho} = \frac{2000}{\sqrt{3}} \times \frac{5.14}{5.14^2 + 0.569 \times 1905}$$

$I_u = 5.35$ amperes.

The minimum power P_u is, according to (**13a**)

$$P_u = P_v - \frac{x_p}{\rho} U_0 I \sqrt{3}$$

$$P_u = 4150 - \frac{5.14}{1905} 2000 \times 5.35 \sqrt{3}$$

$$P_u = 4100 \text{ watts}$$

this being 50 watts less than the total no-load losses.

The minimum current I_m measured was 2.1 amperes. This high value results from the distortion of the current wave (Fig. 7). If the current wave were a sine, the actual current should be:

$$\frac{4150}{2000\sqrt{3}} = 1.2 \text{ amperes}$$

The problem is now to determine, first the ratio of the reactance of loss x_p to the leakage reactance x and then the ratio of the actual losses to the losses given, either by the test with rotor removed or by the short-circuit test.

The ratio of reactances was obtained by a method proposed by the writer[6]. The rotor being removed, a rectangular coil was arranged on the stator core, two sides being parallel with the axis of the machines and the two other sides running along the ends of the core. This coil embraced one pole pitch and consisted of one or more wires.

The stator winding was then supplied with a current I_s of frequency f and readings were taken of the impressed voltage U_s, and also of the voltage u_s across the ends of the rectangular coil.

Let v be the number of turns of the coil, r_s and r_v respectively the resistances of the coil and the voltmeter across the terminals of the coil. The flux across the cylindrical space inside the stator is:

$$\Phi_e = \frac{u_s \times 10^8}{4.44\, f\, v} \left(1 + \frac{r_s}{r_v}\right) \text{Maxwell's} \qquad (\mathbf{16})$$

corresponding to a pressure at the terminals of a three-phase machine of

$$U_e = 2.13 \sqrt{3}\, f\, N\, \Phi_e\, 10^{-8} \text{ volts} \qquad (\mathbf{17})$$

N being the number of conductors in series per phase.

The reactance x due to the leakage of the stator is then:

$$x = \frac{U_s - U_e}{I_s \sqrt{3}} \qquad (\mathbf{18})$$

For a current $I_s = 67$ amperes, the following voltages have been obtained,

$$U_s = 861 \text{ volts}, \quad u_s = 0.441 \text{ volts}$$

at $f = 50$ cycles per second.

The coil was made up of but one wire making $v = 1$; r_s and r_v were

$$r_v = 4.7 \text{ ohms}, \; r_s = 0.17 \text{ ohms}$$

corresponding to

$$\frac{r_s}{r_v} = 0.036$$

Hence,

$$\Phi_e = \frac{0.441 \times 1.036 \times 10^8}{4.44 \times 50} = 0.207 \times 10^6$$

and for $N = 728$ conductors per phase,

$U_e = 2.13 \sqrt{3} \times 50 \times 728 \times 0.207 \times 10^{-2} = 278$ volts

Therefore,

$$x = \frac{861 - 278}{67\sqrt{3}} = 5.02 \text{ ohms}$$

which corresponds nearly to the value of 5.14 ohms found for x_p.

In this case it is permissible to take as the value of the inductive drop of leakage of the stator that of the inductive drop of loss.

While the above test was made at a variable current, readings of the stator losses were taken, (Curve *I*, Fig. 8) giving, for 40 amperes, a loss of 2750 watts, which is practically equal to the above loss,

$$3\, k\, r\, I^2 = 2730 \text{ watts}$$

The losses on short circuit were measured as follows: The machine was driven by a direct-current motor the power input of which was measured with the alternator running on short circuit. Curve *II*, Fig. 8, gives the input to this motor in terms of the current in the alternator.

For the calibration of the motor the alternator was run on no-load, at a variable voltage, the input to the d-c. motor also being measured. Curve *II*, Fig. 2, has thus been obtained. As Curve *I* on the same figure represents the actual power input to the machine under test, it is possible to obtain the exact losses of the direct-current motor. These are measured by the difference of the ordinates of the two curves.

It is thus possible to determine the curve of the short-circuit losses of the machine as shown by (Curve *III*, Fig. 8). For a current of 40 amperes, the total losses on short-circuit are 4850 watts, of which $P_0 =$ 2050 watts, should be subtracted leaving

$$4850 - 2050 = 2800 \text{ watts}$$

This does not differ greatly from the 2730 watts found above for $3\, k\, r\, I^2$.

Therefore, according to the prescribed rules, the no-load loss P_v, at the normal pressure U_0, should be added to the losses on short-circuit. This gives a total value of

$$4150 + 2800 = 6950 \text{ watts}$$

6. Edouard Roth, *Revue Générale de l'Electricité*, 7 February, XVII, p. 217.

as compared with the values 6200 and 6700 watts obtained when the machine is run at the same current as a synchronous motor, either over- or under-excited.

It should be noted that the method of the comet curve, the method with rotor removed and the short-circuit test give the same result for the electric losses. Further, we have seen that the inductive drop of leakage represents the voltage drop of loss.

NOTE. The tests which have been carried out are relatively simple, as they only involve running the machine at no load. The conditions under which they were made do not enable us to determine the losses that may exist on load at power factors other than zero. Presently another series of tests will be carried out that will enable us to determine the value of these losses for full load and to compare them with those found by the separate loss method.

As already mentioned in this article, it is desirable that other manufacturers make similar tests before definite conclusions are established.

THE FORCE BETWEEN MOVING CHARGES*

BY V. BUSH

The classic theory of circuits, as used by electrical engineers, is founded on the assumption that charge is invariant. The new forces which come into play when charges move, that is, when current flows, are expressed in terms of magnetic fields. According to this view the force between a pair of relatively moving charges is made up of two components, one along the line joining them which is always given by Coulomb's law, and a second perpendicular to this, depending upon the velocity, and expressed by means of magnetic fields. This classic concept involves necessarily a change of mass with velocity in order to account for observed results with high-speed electrons. Such a change of mass is also given by the theory of relativity.

There is an alternative theory of circuits, originally advanced by such men as Gauss and Weber, in which there is only one component of force, and in which the concept of the magnetic field is absent. It is entirely adequate to explain all the experimental results which have been obtained with complete electric circuits. For many years it has been practically abandoned, largely on account of the work of Maxwell. The present paper develops this alternative theory and applies it to the behavior of individual electrons in the belief that the alternative theory also deserves careful attention at this time.

In this alternative scheme mass is a constant, and charge is variant. The various circuit effects, such as the force between wires carrying current and induced voltages, are accounted for on this basis by reason of this variation of charge and without the agency of magnetic fields. Some of the possible objections to the idea are then treated.

When applied to relations inside the atom this alternative method of approach gives results similar to those given by restricted relativity and variant mass. The advance of the perihelion of an electron revolving about a positive nucleus coincides with that obtained by Sommerfeld by the use of Einstein's relativity, and applied to the fine structure of the hydrogen spectrum.

According to this present scheme, there is a critical radius in the free motion of an electron about a positive charge, and this appears significant in connection with our knowledge of the atomic nucleus.

CORRESPONDENCE

HIGHWAY LIGHTING

Editor, A. I. E. E., Journal:

The communication on page 354 of the April JOURNAL brings up again the old suggestion of street surface lighting by means of a sheet of light distributed from a source in such a way as to confine it below eye level. This suggestion has no doubt been considered by nearly every engineering specialist on street lighting and presents some very interesting features.

I was especially interested in it a number of years ago but found no opportunity for trying it out until 1917, when the Kensico Dam roadway offered an ideal situation. Mr. H. A. Tinson and Mr. C. A. B. Halvorson working with the engineers of the New York Board of Water Supply, produced an installation which was admirably suitable for those particular conditions.

The study of the problem, however, seemed to indicate rather definitely that such an arrangement would not be economically practical for ordinary highways.

Some of the objections to the low mounted units for general conditions are:

1. Relatively short spacing and therefore numerous lighting units are required.
2. The accurate light-controling equipment is high in first cost and relatively inefficient.
3. Glint effect and silhouetting, which are important in highway lighting, are more or less lost, so that the lighting is less effective for vision than the amount of light on the surface would indicate.

This method of lighting, therefore, does not seem particularly promising under present conditions.

The Kensico Dam installation is described in a paper by C. A. B. Halvorson and A. B. Oday, see *Transactions*, Illuminating Engineering Society, April 3, 1920, page 153, or *Electrical World*, February 14, 1920, page 371.

A Method for Determining the Sign of the Smaller Wattmeter Reading in Balanced Three-Phase Power Measurements

By H. K. HUMPHREY[1]

Member, A. I. E. E.

WHEN three-phase (three-wire) power is measured by the two-wattmeter method, the smaller reading may be either positive or negative, so that the total power, which is the sum of the two wattmeter readings, may be obtained by adding the smaller reading to the larger in one case, and by subtracting it in another case. On balanced load this reading is positive, and must be added, when the power factor is greater than 50 per cent; it is negative and must be subtracted when the power factor is lower than 50 per cent. However, unless the power factor is known, it is necessary to make sure by some other means which is the correct sign for this smaller reading; failure to do so has sometimes led to curious if not serious error. For balanced load, there are in use several methods of determining the sign of this reading at the time of test. These require that either the connections or the load be altered and that additional data be taken. Often enough, however, this sign is questioned only after the test is completed and the apparatus scattered, and in this case it is apparent that a determination which depends upon a simple consideration of the usual instrument readings would be useful. Such a method is the one to be described. It is applicable only to balanced three-phase loads and sinusoidal wave forms, but in itself gives an indication of the extent to which results are affected by variation from these conditions.

The belief seems to be general that for any set of readings of line voltage, E_L, line current, I_L, and the two wattmeter readings, W_1 (larger) and W_2 (smaller), there are two possible conditions of power factor, one greater than 50 per cent in which W_2 is positive, and one lower than 50 per cent in which W_2 is negative. That is, for instance, if E_L is 200 volts, I_L, 31.1 amperes, W_1, 5.60 kw., and W_2 + 0.34 kw. (power factor 55 per cent), there would be expected for some lower power factor the readings; E_L, 200 volts, I_L, 31.1 amperes, W_1, 5.60 kw., W_2 − 0.34 kw. This is not the fact, however; there is no such possible set of readings on a balanced system with sine-wave voltage and current. The condition of load which would give a reading W_2 of − 0.34, with the same values of voltage and current would give a reading W_1 of 5.23 kw., not 5.60; or, for the same voltage, the load which would give 5.60 kw. for W_1 and − 0.34 kw. for W_2 would require 33.3 amperes, not 31.1. The accompanying curve, which shows each wattmeter reading, W_1 and W_2, separately for all values of power factor ($E_L I_L = 1.0$), will make this fact clear. The curves are obtained by plotting against cos ϕ the ratios $\frac{W_1}{E_L I_L}$ and $\frac{W_2}{E_L I_L}$ calculated from $W_1 = E_L I_L \cos(\phi - 30 \text{ deg.})$ and $W_2 = E_L I_L \cos(\phi + 30 \text{ deg.})$[2]

Stated in a somewhat different form, any particular pair of wattmeter readings (sign considered, of course) can be obtained for only one value of the product $E_L I_L$ or of volt-amperes ($v\sqrt{3}\,E_L I_L$); this value is not the same for positive W_2 as for negative, which may be shown as follows

The power is, of course, $W_1 + W_2$; the wattless volt-

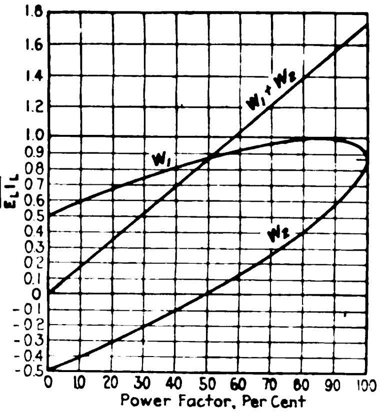

Fig. 1

amperes are $v\sqrt{3}(W_1 - W_2)$[3]. From these, the volt-amperes, VA, can be computed:

$$\begin{aligned} VA^2 &= (\text{watts})^2 + (\text{wattless volt-amperes})^2 \\ &= (W_1 + W_2)^2 + 3\,(W_1 - W_2)^2 \\ &= 4\,(W_1^2 + W_2^2 - W_1 W_2) \qquad (1) \end{aligned}$$

Equation (1) shows that the volt-amperes are always larger if W_2 is negative. But the volt-amperes can also be computed from

$$VA = v\sqrt{3}\,E_L I_L \text{ or } VA^2 = 3\,E_L^2 I_L^2 \qquad (2)$$

The values of VA (or of VA^2), computed from the data by (1) and by (2), will not check if the wrong sign has been used for W_2; but if the proper sign has been used, and if there is no disturbing factor such as unbalance, they will agree; failure to check for both assumptions as to sign of W_2 signifies an error in either test or computation, unbalanced load, or harmonics in voltage or current, and the degree of disagreement may be taken as a measure of the effect of these disturbing conditions.

1. Assistant Professor of Electrical Engineering, The Rice Institute, Houston, Texas.

2. See R. R. Lawrence, Principles of Alternating Currents, p. 331.

3. R. R. Lawrence, op. cit., p. 334.

One method of checking, then, is to compute the volt-amperes not only from the voltmeter and ammeter readings (2), but also from the wattmeter readings; (1), equation (1) should be used twice, once taking W_2 positive, the other time negative; unless disturbed by faulty readings, unbalance, or distorted wave-forms, one of the values computed from (1) will check the value obtained from (2), and the sign used for W_2 in the checking case is clearly the correct one. To return to the example previously given, for wattmeter readings W_1 5.60 kw. and W_2 + 0.34 kw., the kv-a. must be 10.87, while for $W_2 - 0.34$ the kv-a. must be 11.54. Since the kv-a. computed from $v\sqrt{3} \times 200 \times 31.1 \times 10^{-3} = 10.78$, it is clear that the positive sign is correct for W_2, and further, that meter inaccuracies, or careless reading, or unbalanced load conditions, or distorted voltage or current, collectively, are producing a discrepancy of less than 1 per cent.

Further examples of the use of this method are given in the table (to the left of the heavy dividing line). The data for these examples were selected from actual runs in which the power factor varied steadily from a low value to something well over 50 per cent, so that for each set of readings the sign of the smaller wattmeter reading was known without question; in each case, except the fifth, the particular reading for which the power factor was nearest 50 per cent, and for which, therefore, the method would most likely fail, was chosen.

A variation of the method which may be more convenient in some cases is the computation and comparison of power factors instead of volt-amperes. Power factor is commonly computed either by the ratio

$$P f = \frac{W_1 + W_2}{v\sqrt{3}\, E_L I_L}, \text{ or by taking the ratio } k = \frac{W_2}{W_1}$$

and finding the power factor on a curve plotted against k.[4] These two values of power factor will agree under the same conditions as the values of volt-amperes. The accompanying curves may be used for the same purpose and they seem even more simple. If the ratio $\frac{W_1}{E_L I_L}$ be computed, the power factor may be read at once from this curve; the other ratio, $\frac{W_2}{E_L I_L}$, should fall upon the other curve at the same power factor. It will be noted that the second ratio, $\frac{W_2}{E_L I_L}$, is used only as a check upon balance, etc.; it is not needed to determine the power factor. And, indeed, the curve itself is not needed to determine the sign of W_2, for the ratio $\frac{W_1}{E_L I_L}$ is always less than 0.866 $\left(= \frac{v\sqrt{3}}{2}\right)$ when W_2 is negative (power factor less than 50 per cent), and is always greater than 0.866 when W_2 is positive (power factor greater than 50 per cent), so that this ratio alone is sufficient unless a further check is desired. Using the data of the previous example,

$$\frac{W_1}{E_L I_L} = \frac{5600}{200 \times 31.1} = 0.900 > 0.866; \text{ therefore,}$$

W_2 is positive, and from the curve, the power factor is 55 per cent; the ratio $\frac{W_2}{E_L I_L} = \frac{+340}{200 \times 31.1} = 0.055$, which indicates a power factor of 54.5 per cent. Other examples of this use of the method are also given in the table; these are to the right of the heavy dividing line.

It is clear that the methods given are but variations of one. The more convenient should be used according to circumstances or personal preference; either one is a very easily applied check upon the readings, the connections, and the sign of the smaller wattmeter reading.

COMPUTATIONS FROM ACTUAL DATA, SHOWING METHODS OF DETERMINING SIGN OF W_2 AND CHECKING READINGS

E_L	I_L	W_1	W_2 (sign known)	$v\sqrt{3}\, E_L I_L$	Kv-a. from wm. taking $+W_2$	Kv-a. from wm. taking $-W_2$	sign of W_2	$\frac{W_1}{E_L I_L}$	sign of W_2	$\frac{W_2}{E_L I_L}$	Power factor from W_1	Power factor from W_2
201	23.4	3.76	−0.56	8.15	7.03	8.14	−	.799	−	.119	39.0	39.0
200	31.1	5.60	+0.34	10.78	10.87	11.54	+	.900	+	.055	55.0	54.5
215	18.6	3.46	−0.04	6.93	6.88	6.96	− *	.865	−	.010	50.0	49.3
213	20.6	4.06	+0.54	7.61	7.64	8.71	+	.925	+	.123	60.0	60.5
207	15.7	1.82	−1.44	5.64	3.31	5.65	−	.560	−	.443	7.0	6.5
217	18.8	3.56	+0.06	7.07	7.06	7.17	+	.872	+	.015	51.0	52.0

Sample calculation for first line: Column 5, $v\sqrt{3} \times 201 \times 23.4 \times 10^{-3} = 8.15$ kv-a.

Columns 6 & 7, $4 \times 3.76^2 = 56.55$

$4 \times 0.56^2 = 1.25$

Sum 57.80

For $+W_2$, subtract $4 \times 3.76 \times 0.56 = 8.42$

$57.80 - 8.42 = 49.38$; $v\sqrt{49.38} = 7.03$

For −, add 8.42: 66.22; $v\sqrt{66.22} = 8.14$

Column 8, since column 7, using $-W_2$, checks column 5, W_2 is negative

Column 10, Since $\frac{3760}{201 \times 23.4} = 0.799 < 0.866$, W_2 is negative

Columns 12 & 13, power factors read from curves at 0.799 and −0.119 respectively

*Note: The data in this line are such (W_2 about 1 per cent of W_1) that a certain determination of the sign of W_2 is difficult. While the method gives the correct result in this case, it could hardly be relied upon in general.

Sectional Electric Drive for Paper Machines

BY R. N. NORRIS[1]

***Synopsis.**—This paper describes a system of electric control for sectionalized electric drive which makes use of a mechanical differential. Further, it discusses the drive of the constant-speed end of the paper machine and the general advantages of electrical sectional drive for paper mills. Some figures are given on the power consumption of several classes of mills. The type of drive described has been used for some time in Europe and Canada and it has now been successfully introduced in the United States.*

In this paper will be described a system of sectional electrical drive which utilizes a mechanical differential as the basis of its control. First, this particular type of system, called the Interlock System, will be described and this will be followed by comments on the drive of the constant-speed end of the paper machine, with statement of the advantages of sectional driving in general.

Like all other sectional electric drives the Interlock installation consists essentially of a d-c., compound-wound, interpole generator with an exciter, which exciter supplies the excitation current to the field circuit of the generator and also the field circuits of the several section motors.

It is essential that the generator and exciter be designed to give good regulation under varying load conditions and that voltage regulators be provided to maintain a steady voltage in order to compensate for variations in load or speed of the prime mover.

Fig. 1 is a schematic diagram and layout of a typical installation showing the section motors at the couch, press, dryers and calender sections of a newsprint machine. This illustration does not show the reel or winder sections, but the reel and additional calender sections or smoothing roll sections, etc., can be driven in a similar manner, and the sketch serves to show the arrangement of the drive in general.

Each section of the paper machine is driven by a compound-wound interpole d-c. motor, which may be either directly coupled to the paper machine in-driving shafts or coupled thereto through some form of gear unit—double helical, worm, chain, etc. Sometimes a very convenient arrangement is to use direct-coupled motors for the heavier powers at couch, dryer and calender sections, and geared units at the press sections.

Fig. 2 shows direct-coupled motors driving a 234-in., 1200-ft. per min. newsprint machine. The sectional drives are housed in a separate room, the in-driving shafts of the paper machine passing through the walls into the machine room proper.

Fig. 3 shows an all-geared arrangement of Interlock drive, and Fig. 4 shows the semi-geared arrangement referred to above. Fig. 5 is a line drawing of a direct-coupled motor and also shows control unit.

In large newsprint machines the dryer sections consisting as a rule, of 40 to 46 cast-iron cylinders, five or six feet in diameter and up to 240 in. face, are usually geared together and driven by motors driving through two pinions on to the same load.

However, the arrangement of the machine, whether direct-coupled, gear-driven, or, as here termed, semi-geared, is a matter of detail which may vary with the particular case in question.

As illustrated by Fig. 1, a d-c., adjustable-voltage generator, G, supplies the necessary power to the section motors, $A\,1$ to $A\,7$. This generator is separately excited, and the exciter also supplies the excitation

current to the field circuit of the several section motors.

$A1$ to $A7$ represent the various section motors, which, on the couch, and the two dryer sections, are direct coupled to the intake shafts. On the three press sections and the calender section, a single reduction herringbone gear is employed. For purposes of simplicity no main switchboard is shown in this illustration; however, a main switchboard is provided between the generator and exciter and the main busbars, $D\,C$, and exciter busbars, $E\,B$. On the couch section is shown one of the motor starting panels, F, with the

Presented at the Regional Meeting of District No. 2 of the A. I. E. E., Cleveland, Ohio, March 19, 1926.

necessary connections from the field and armature circuits of the motor, and the differential regulator D; $F1$ is the starting panel for the dryer motors.

Speed adjustment within the desired range of the paper machine is obtained, in the case of large newsprint machines, entirely by variation of the generator voltage which is applied to the section motor armatures.

Fig. 2—Direct-Couples Motors Driving a 234-in.,1200-Ft. per Min. Newsprint Machine

In book-paper machines, or other machines requiring large speed ranges, this speed adjustment is obtained by a combination of generator voltage regulation as above and variation of the field strength of the section motors. The whole of this speed adjustment is obtained from a combined regulator which is operated by one handwheel or by remote-control, push-button operation.

The arrangement of the Interlock control system shown in Fig. 1 consists of a master shaft N, located in

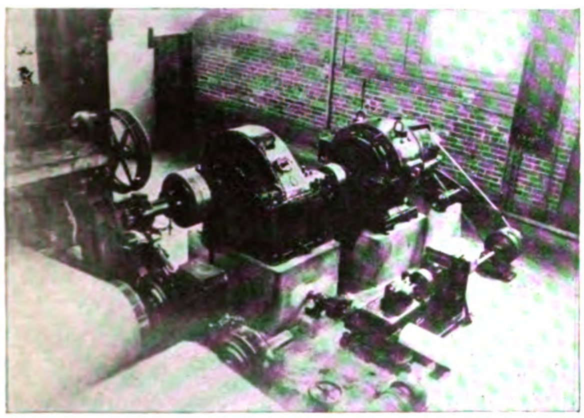

Fig. 3—Interlock Drive in Operation on Third Press Section of 234-in., Newsprint Machine, 600/1000 ft. per Min

any convenient place, and extending the entire length of the variable speed end of the paper machine. This master shaft transmits practically no power, as it is only a governor shaft. The power required to drive the master shaft is negligible, and the whole shaft, with the differential regulators but without the draw control belts in position, can very readily be turned by hand from any point of the shaft. At each section, the differential control gear, D, is inserted.

In Fig. 1 the shaft is shown passing underneath the reduction gear units, but it, of course, has no connection with these units and is simply shown in this position as being a convenient position for it.

It can be placed in any convenient position—under the floor if desired, with the regulator equipment sus-

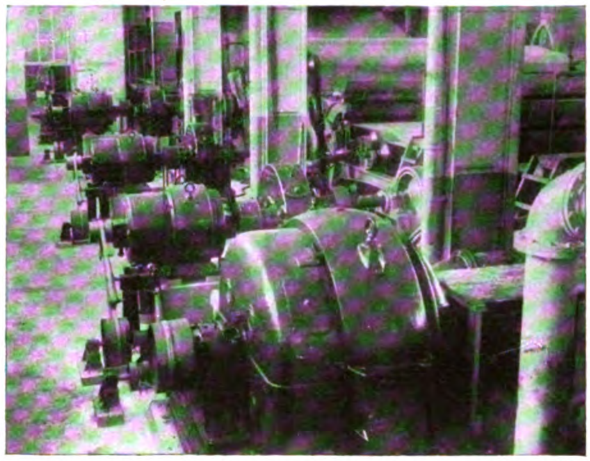

Fig. 4—Semi-Geared Arrangement of Interlock Drive

pended from the ceiling,—and if the master shaft is an insuperable difficulty either in the layout of the plant at the back of the paper machine or in reality in the mind of the prospective user, then it can be replaced by a synchronous generator and synchronous motor at each section; but in the author's opinion the shaft is the better drive from a point of simplicity and reliability and provides a more rigid and positive drive for the control units.

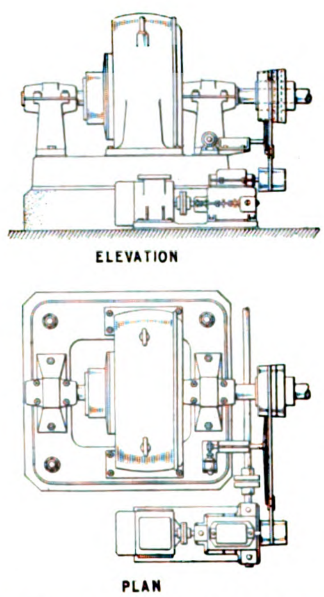

Fig. 5—Showing Direct-Coupled Motor and Control Unit

The master shaft can be driven by either a small, separate electric master motor or from one of the sections of the paper machine, preferably the dryer section, as shown in Fig. 1. This master shaft when driven from the dryer sections is driven by means of a small chain

drive or a small geared drive, whichever happens to be the more suitable for the layout in question.

A diagrammatic illustration of the differential-control apparatus, geared to the master shaft at each of the sections to be controlled is given in Fig. 6. This

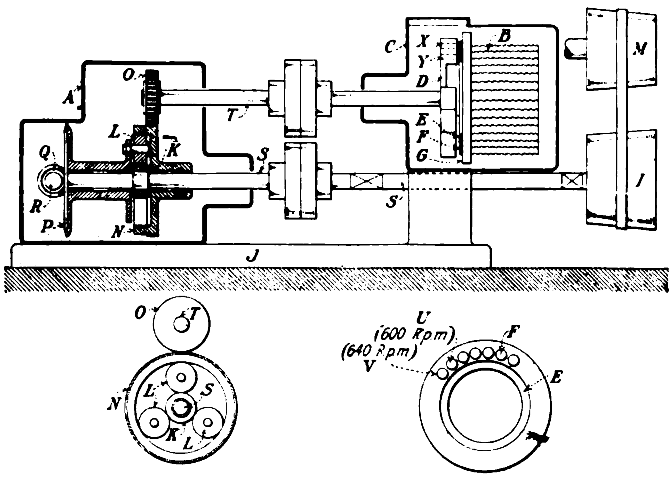

FIG. 6—DIAGRAMMATIC ILLUSTRATION OF DIFFERENTIAL CONTROL APPARATUS GEARED TO MASTER SHAFT AT EACH SECTION TO BE CONTROLLED

differential control consists of bevel gear, *P*, free to revolve on cone pulley shaft, *S*, and a bevel pinion, *Q*, which is mounted on the master shaft, *R*. Attached to the bevel wheel, *P*, are three planetory pinions, *L*, which mesh with the sun wheel, *K*, the last named being keyed to the cone-pulley shaft, *S*; the pinions, *L*, also mesh with the internal teeth of the annular ring, *N*, which turns freely on shaft, *S*. Around the outside of the annular ring, *N*, are teeth that engage with another spur wheel, *O*, mounted on shaft, *T*, this shaft being connected through a coupling to a shaft carrying the brush arm, *D*, in the automatic differential regulator *C*.

If the shaft, *S*, carrying the cone pulley, *I*, which is driven by the section motor, runs (in the opposite direction) at the same speed as the bevel gear, *Q*, located on the master shaft, then there will be no re-

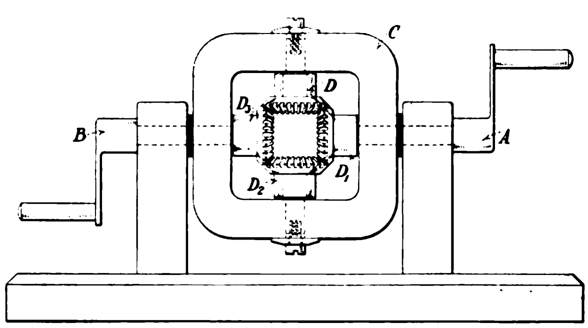

FIG. 7—BEVEL-GEAR DIFFERENTIAL

sultant movement of the annular ring, *N*; but however slightly these two may vary in angular position relative to each other, a correct and instantaneous response is given on the annular ring, *N*, and coincidentally on the wheel, *O*, which is driven by the annular ring. The bevel pinion, *Q*, is driven by the master shaft in each case, and the sun wheel, *K*, is driven from the cone pulley through the section motor itself, which must be controlled in each case. Therefore, any tendency of difference in angular relation between the master shaft and the motor to be controlled is instantly reflected on the annular ring.

An epicylic train of wheels is an elusive creature when it is desired to know exactly what takes place, and to more readily grasp the simple and effective nature of the control it is easy to look upon this as a bevel gear differential as Fig. 7. This consists of a small frame, *C*, with four small bevel gears, *D*, *D*1, *D*2, *D*3, all of the same size and having the same number of teeth. Gears, *D* and *D*2, turn on journals that are attached to the frame *C*; gear *D*1 is keyed to the shaft, at the other end of which is keyed the handle *B*; and gear *D*3 is keyed to a shaft, at the other end of which is keyed the handle, *B*; the frame *C* is free to turn on these two shafts. Suppose the frame to be held stationary and handle *A* to be turned clockwise; then, gears *D* and *D*2 will turn in opposite directions, and will cause gear, *D*3 to turn in a direction opposite to that of gear *D*1, which is keyed to the same shaft as the handle *A*. The two handles *A* and *B* will, therefore, turn in opposite directions at the same speed in revolutions per minute.

Now if the frame, *C*, be free to turn and handle, *A*

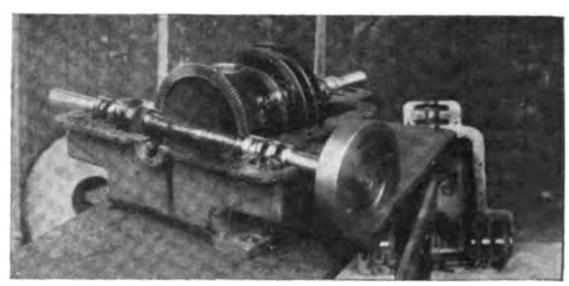

FIG. 8—EPICYCLIC INTERLOCK DIFFERENTIAL WITH COVER REMOVED

and *B*, together with gears, *D*1 and *D*3, are turned in opposite directions at the same speed, the frame *C* will remain stationary, the conditions then in so far as the revolutions of the gears are concerned, being exactly the same as they were when the frame was held stationary. If, on the contrary, while *A* makes 100 turns, *B* makes one turn more or less than this, *i. e.*, 99 or 101 turns, the frame, *C*, must make half a turn forwards or backwards, the same result that would be had if *D*1 were stationary and handle, *B*, made one turn.

The angular displacement has nothing to do with time; it depends only on the difference between the number of turns made by the gears, *D*1 and *D*3, regardless of whether this takes one minute or one year. Therefore, if in *any* period of time, gear *D*1 has an angular velocity of 1 deg. greater or less than gear *D*3, the frame *C* must be displaced ½ deg. from its initial position.

The Interlock system of control is merely the application of this principle to the regulation of the speed of the electric motor connecting a single field rheostat to the third member of the differential, which, in the epicyclic differential Fig. 6, is in the ring, *N*, and is so connected by gear, *O*, shaft, *T*, and coupling, *X*.

Fig. 8 shows the epicyclic Interlock differential with the cover removed, and Fig. 9 closed, and it gives a good idea of the robust construction. The gears all

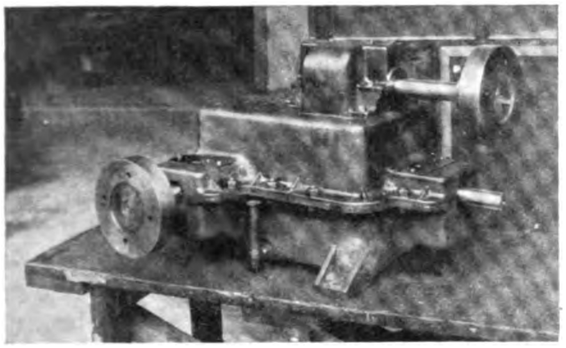

FIG. 9—EPICYCLIC INTERLOCK DIFFERENTIAL WITH COVER CLOSED

run in oil, and being enormously large in comparison to the power required, they will run indefinitely without wear. In fact, after four years' operation at 24 hours per day on a large Canadian newsprint installation, the gear teeth still show the signs of the hobbing cutters which milled them out of the solid.

The field regulator portion of the control contains a large number of resistance units which are cut in and out of circuit of the motor field, the circuit being completed through the brushes *X* and *Y* which travel over a number of contacts *F* and form a complete circuit through the brass ring contact *E*. In practise, the brush arm, *D*, quietly breathes between the two contacts, of which there are 80 to 100 on the regulator.

The accuracy with which the desired speed is required is so great that if there were a million contacts instead of 80, they would not suffice to have one for every flicker in speed; the brush would steadily breathe but the movement would still be between the contacts, one on each side of the desired speed. Referring to the lower right hand part of Fig. 6, suppose that one of these contacts *U* represent 600 rev. per min., on the motor, that the next contact, *V*, represent 640 rev. per min. and that a speed of exactly 620 rev. per min. on the motor were required; then the brush arm would be quietly breathing between the two contacts *U* and *V*, spending sufficient time on either contact to produce an average field that will give a perfectly steady motor speed of 620 rev. per min., the speed that was desired for the moment. Should this desired speed be 635 rev. per min. say, then the action is exactly the same as before, except that the arm spends a fraction more time on contact *V* than on contact *U*.

If the load varies on any motor, it will immediately tend to speed up or slow down, which will produce a tendency to change any angular variation between the two halves of the differential. The annular ring, *N*, will move and the rheostat arm, *D*, will take up this new position to suit the load in question.

The control is absolutely automatic and instantaneous for all conditions of load which may occur, and no hand adjustment of the motor field strength is required for any load change which does occur such as happens at the press sections, for instance, when the weights are changed, or at the couch section when the vacuum is altered.

If the machine operator desire to change the draw between sections of the paper machine, he has only to move the belt on the cone pulley, *I*, and cone pulley, *M*, Fig. 6, attached to the motor shaft; the motor is then trying to drive, *K*, at a speed that is different. This immediately sets in motion the annular ring *N*, which comes to rest again in a moment, after moving through a few degrees of arc, enough to alter the resistance in *C*; harmony is then once more established, and the motor, running at a different speed, as desired, is still driving the sun wheel, *K*, at exactly the same speed as that of the bevel pinion. The 1½-in. belt may be shifted on the cone pulleys by a hand-wheel or by remote control of a fractional h. p. motor that operates the belt-adjustment gear.

Starting up of the respective section motors is obtained usually by means of automatic push-button-operated contactor motor-starting panels. The push buttons can be located anywhere and are usually on the front of the paper machine at the respective sections, the panels themselves being arranged usually as a switchboard in a substation preferably alongside the

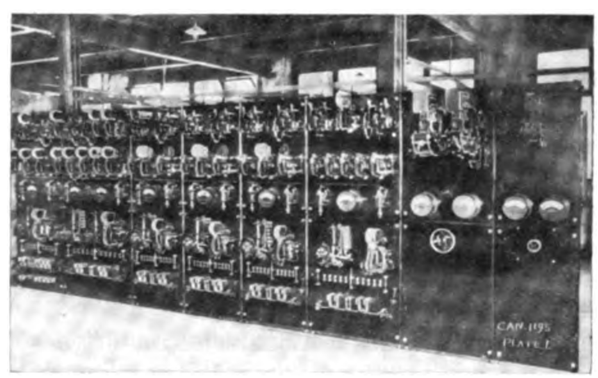

FIG. 10—TYPICAL SWITCHBOARD FOR AUTOMATIC PUSH-BUTTON OPERATED MOTOR STARTING PANEL

generator and main switchboard; Fig. 10 shows a typical switchboard of this nature.

The starting panels are provided with resistance units capable of giving very slow crawling speeds which are required when putting on new Fourdrinier wires or felts at the press sections or the dryer sections, and also for the purpose of inching round the various sections for inspection purposes.

Each section can be started, run at slow speeds, or stopped, independent of the other sections, without

interfering with any of the other sections. They will all continue to run at the predetermined speed. Should the master section shut down—whether it is the dryer sections, or a small master motor—all the other sections automatically still continue to run at the speed at which they were first operating.

Of course, for the time being, while the master section is standing, the Interlock is not in operation, but immediately the master section has again been brought to full speed the other sections automatically go into interlock.

These conditions are all made by the means of simple automatic devices.

Motors

All motors, whether for direct-coupled machines or for geared installations are totally enclosed and supplied with forced ventilation. This is a distinct advantage at the back of the paper machine, as behind the dryer sections high temperatures are met, and behind the wet end of the paper machine at the couch and press sections a great amount of splashing of water mixed with paper stock occurs which is not good for the windings of any electric motor. Furthermore, at times careless use of a hose by some operator may ruin a motor. All this is safe-guarded against by the use of totally enclosed machines.

This Interlock sectional electric drive which was developed by the Harland Engineering Company has been in successful use since 1914 when it was first installed in Scotland on a small machine having a wide speed range of ten-to-one. During the four or five years previous to this installation there were two sectional electric drives in operation in Great Britain. One of these was not altogether successful and was replaced by mechanical drive. The other was converted to the Interlock differential-control system and is the drive in Scotland referred to above. This equipment is still in operation. Since the installation of this equipment, constructional improvements in mechanical and electrical details have been made as a result of experience, but the principles of control and operation have not been changed.

Before passing from sectional electric drive reference will be made to the driving of the constant-speed end of the paper-machine, which seems liable to suffer from neglect owing perhaps to the tremendous interest that has been focused on its sister part.

The paper-machine drive has always been separated into two groups,—the constant speed part, and the variable speed end. The development of the sectional electric drive has provided for the latter, but there appears to be little movement as yet to study and change driving arrangements of the constant speed end. Where a separate driving unit is provided it is quite usual to have two generators and exciter, all driven together, consisting of a d-c. generator, its exciter (which also excites the sectional motor fields) for the variable speed end, and an alternator to provide a-c., three-phase supply to operate the constant speed end. This constant speed end may be driven by one motor, or it may be divided into groups, but no attempt seems to be made to adjust the running speed of its elements to suit the changing speed of the paper machine.

A little progress has already been made in one or two mills in so far that in a few cases the pumps, etc., are being driven by separate motors, thus eliminating belts as far as possible. For this purpose the d-c. motor has been employed, which has wherever possible been direct coupled to pumps, and which allows a moderate amount of speed control by shunt regulation, thus enabling the speed of the pump to be adjusted to suit the operating speed of the paper machine itself. For such a purpose, direct current clearly has an advantage, and the author believes will gradually be more widely adopted.

It is true that some portions on the constant speed part have been initially conceived and developed with a drive from a steam engine or a counter shaft in mind, and perhaps do not seem to be specially suited for direct coupling to a motor, but, doubtless with the development and more extended use of an individual drive on the constant speed end, designs which the business seems to demand will gradually be evolved. In such matters engineers do not usually lag far behind. With such an arrangement the speeds of the various pumps can be adjusted to suit the output required of them, which to a moderate extent varies with the speed of the paper machine. In this way economies in power can be attained and it is believed other advantages also will result. It will be evident that the control of this part of the machine will be more complete than is otherwise possible.

The following table gives averages of some hundreds of power readings taken from time to time on various machines. The first row covers readings on 14 machines of similar size in operation, and the second row, 6 machines. The others are averages on selected individual machines:

From several readings obtained from machines having mechanical drives with single motor the average e. h. p. per inch of width for 100 ft. per min. is 0.35 e. h. p.

Then there is the very interesting side of the question relating to the effect of sectional driving on the thermodynamic efficiency (a) of the paper machine itself—(b) of the paper mill as a whole,—as a result of the saving in power effected by sectional driving.

From the power table just given, it will be seen that a 234-in. paper machine, operating at 1000 ft. per min. would require 472 e. h. p. A mechanically operated machine operating at the same speed would require about 819 e. h. p.

Assuming that the average output of paper from the machine is 125 tons per twenty-four hours, and that the average steam requirements for drying the paper are 3.75 lb. of steam per pound of paper, then we get a steam requirement in the drying cylinders of the paper machine, 38,900 lb. of steam per hour.

A steam turbine operating under normal conditions usually met with in a paper mill would have a water-rate of about 38 lb. of steam per e. h. p.-hr. allowing for generator efficiencies, so that by utilizing to the fullest extent the power in the steam required in reducing it from the normal pressure to the pressure required for drying in the paper machine cylinders we can obtain approximately 1000 e. h. p.

Now, if the paper machine is driven mechanically, the balance of horse power so obtainable (181. e. h. p.) would hardly justify the installation of an additional generator to supply the excess power to the constant-speed end of the machine, but the balance of power obtainable by using sectional drive, 528 e. h. p., is sufficient to justify this and is usually enough to drive the whole of the constant speed end of the paper machine. This renders the paper machine an individual unit, which has many advantages.

Sectional driving of paper machines has also had its effect upon building design by reducing the cost of basements and saving space.

The foregoing does not pretend to deal with the general advantages to be obtained in the use of sectional electric drive as compared with mechanical drive. These are becoming so generally well-known that it is only necessary to outline briefly a few of them—such as the elimination of belts and ropes, and their consequent very high up-keep costs; the saving of power as is shown on the power figures given above; the very much steadier speed control between sections of the paper machine which result in a better quality and production of paper from a given machine with a given quality of stock supplied to the machine.

Each section of the paper machine is made a separate unit and with electrical indicating instruments it is possible to detect faults which may arise on the paper machine itself which allows of investigation and probably rectification of the trouble before it becomes serious, whereas with mechanical drive very probably the first indication of trouble is when the trouble has become serious enough to necessitate expensive repairs.

The greater ease in handling the paper machine by the paper mill operators is very marked and needs to be experienced to be realized. The absence of ropes and belts on the back side of the machine makes the machine more accessible, which all helps in the upkeep and maintenance of the plant and reducing life hazard.

Due to the very even starting torque exerted by electric motors, particularly of the d-c. type, dryer gear life is increased as compared with the mechanical drive where power application of the dryer gears is usually by clutch or snatching of cone pulleys which puts sudden stress on the gears.

These notes have been put together on the assumption that they will be read to those who have some knowledge of paper machines and are interested in present and future operation and development. There is to my mind a great field in the United States for conversion of old mechanically driven machines to sectional drives and although I expect there are many paper makers who will disagree with me, I maintain that there are very many advantages to be obtained in doing this.

One, of course, still meets the man who says the mechanical drive is good enough and he is clearly right from the standard of his own point of view. Everybody knows that mechanical drives have made and will still make good paper. In the beginning it was the large powers and high speeds required by the large newsprint machines which forced forward this subject of sectional driving, although its actual development was accomplished before the advent of the large high-speed machine.

The steady increase in the size of newsprint machines finally made sectional driving a necessity.

When its reliability became established, it made wide machines and high-speed machines more readily available than formerly. Its advent also has apparently had an influence on the design of the paper machine itself as regards the widths and speeds at which it can be built.

The reliable nature of the drive in operation on newsprint machines has been proved and has demonstrated also that for the small book machines, etc., the same good results can be obtained: in fact, it is becoming more general, and nearly all new book machines are fitted with sectional drive. As stated before there is a big future for the conversion of existing machines to sectional drive.

In this connection it is interesting to consider that some form of sectional drive has been constantly the subject of research by independent peoples in different parts of the world; contemporary with the work which we were doing in Great Britain, other people were carrying on similar experiments on this Continent and in Europe. All these experiments, the author believes, were made quite independently of each other showing a widespread belief in the necessity and usefulness of sectional drive.

Can the Thermal Capacity of Electric Machines Be Made a Simple and Practical Element of Rating?

BY A. E. KENNELLY*

PREFACE

THE subject of this paper has been suggested to the U. S. Committee, by the Council of the I. E. C., as suitable for a report at this 1926 meeting, and has been assigned to the writer for preparation. The writer does not claim any authorization from the U. S. National Committee to present its views officially on the subject. He merely submits the paper as expressing personal opinions, aided, however, by the records and reports of a certain group of engineers who have given special attention to the thermal constants of electric machines, and who are mentioned in the following text.

BRIEF ANSWER AND PURPORT OF THE PAPER

It is believed that the thermal constants of electric machines in the variable regime, (especially their binary time constants), can, in many cases, be used in a very simple way for practical operating purposes. It is not, however, recommended that such thermal constants should be introduced into the rating of machines at the present time. It is, nevertheless, recommended that these thermal constants should be regarded as useful subsidiary information concerning machines, until such time as engineers may have become more generally familiar with their application and use. All machines do not seem equally subject to their useful application. Attention should be called to the practical service that the purchasing and operating engineer may derive from the thermal constants of machines. It seems likely that, at some future time, after the matter has been more thoroughly investigated by designers, manufacturers, testers, and operators of electric machinery, these thermal constants, including thermal capacity, may be found sufficiently important and reliable to be promoted from the present category of useful subsidiary information, to the category of rating constants of machines.

It should be pointed out that but little of the technical material in this paper is new. It is mainly collected here for convenience of reference.

Thermal Constants of Electric Machines may be divided for convenience into two classes, namely,

1. Steady-regime constants.
2. Variable-regime constants.

Class 1 may be considered to contain the following, for any machine or element of the same (such as field, armature, internal or external part of winding, stator rotor, commutator, bearing, etc.)

a. Hottest-spot maximum safe temperature.
b. Maximum accessible measurable temperature.
c. Ambient temperature, θ_a.
d. Instantaneous temperature rise of machine or element θ.
e. Instantaneous temperature, $\theta + \theta_a$.
f. Ultimate temperature rise under continuous rated load, Θ.

All of the above constants enter either directly or indirectly into the continuous rating of a machine from the thermal standpoint, and need no discussion here.

Class 2 may be considered to contain the following thermal constants for any machine or element:

A Ultimate temperature rise characteristic $\Theta - P$, under different sustained percentages of rated load.

B Time constant or constants of machine or element τ hours or minutes

C Thermal capacity of machine or element k watt-hours per deg. cent. temperature rise above stationary ambient.

D Specific thermal capacity of material in a machine or element—watt-hours per kg. and deg. cent.

E Dissipation constant of machine or element s watts per deg. cent. temperature rise.

The variable-regime thermal constants (*A*) to (*E*) are the main subjects of discussion in this report.

UTILITY OF VARIABLE-REGIME THERMAL CONSTANTS

Characteristic A. The most important of the class 2 here considered is probably *A*, the ultimate temperature rise characteristic $\Theta - P$. This is a characteristic curve connecting the ultimate temperature rise of the machine, presumably at its max. accessible temperature location, for different percentages of rated load. When drawn on logarithm paper, such a curve usually approximates to a straight line over a moderate percentage range of load. Thus, in Fig. 1, the particular machine supposed to be there designated develops an ultimate temperature rise of 40 deg. cent., in a specified element, at continuous rated load. It also develops 50 deg. cent. rise at 1.15 times rated load, and 76 deg. cent. at 1.5 times rated load, if the straight line characteristic *A O C* is adhered to over that range. This straight line rises 1.6 units of ordinates in one unit of abscissa length; so that this straight line represents a temperature rise increasing as the 1.6th power of the load, over the range it may be taken to cover.

An operating engineer, knowing the continuous rating of the machine, can ascertain with the aid of such a characteristic the temperature rise of the element considered, over a certain range of steady loads, from, say, 0.50 to 1.5 times rated load. The maker of the

*Honorary Secretary of the U. S. National Committee, I.E.C.

A report presented to the International Electrotechnical Convention at its U. S. Meeting in April 1926.

machine may not have made ultimate temperature rise measurements at different steady loads; and therefore may not be prepared to give this $\Theta - P$ characteristic. He will in many cases, however, have secured such a series of three or four different ultimate temperature rises, at different percentages of rated load, on some similar machine of the same dimensions and speed. The purchasing engineer may be able to obtain this auxiliary information from the maker, and so construct

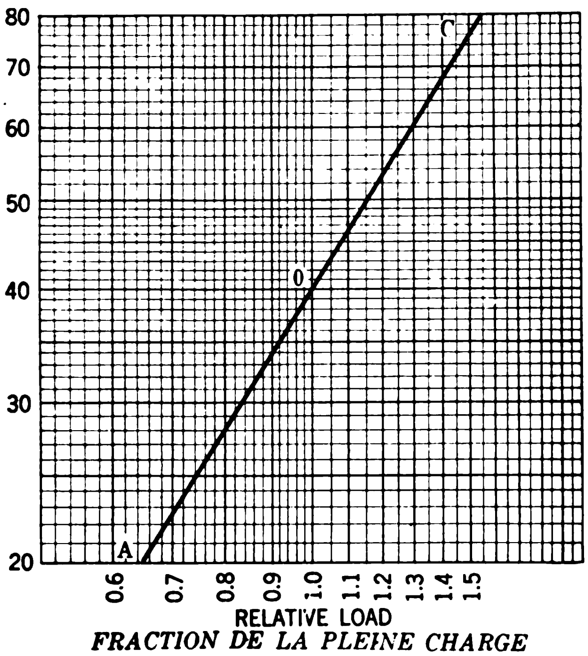

FIG. 1—APPROXIMATE STRAIGHT LINE RELATION BETWEEN ULTIMATE TEMPERATURE RISE AND STEADY LOAD FOR A PARTICULAR DYNAMO MACHINE

a $\Theta - P$ characteristic which is likely to be fairly reliable. The operating engineer may subsequently be able to check this characteristic from the observed behavior of the machine under some particular steady load or loads in service.

Time Constants B. It is well known* that when a machine passes from one steady load to another, at constant ambient temperature, the temperature rise of any element will change, in the simplest case, with time, according to a simple exponential curve or time-constant curve. Owing to complexity of thermal relations among the different elements of a machine, the temperature rise may depart materially from a simple exponential curve; but in many cases it conforms to such a curve sufficiently closely for practical purposes.

Two principal varieties of thermal time-constant present themselves:

1. The exponential time constant τ_ϵ, fundamental in the theory of such curves, but awkward to use.
2. The binary time constant τ_2, suitable for practical use.

In any exponential curve, the exponential time-constant τ_ϵ is that interval of time during which the temperature rise comes within $1/\epsilon$, or 1/2.718, or 36.8 per cent, of the ultimate rise. In a period of 2 τ_ϵ, the rise will come within $1/\epsilon^2$, or about 13 per cent, and in 3 τ_ϵ within $1/\epsilon^3$, or about 5 per cent, of the ultimate rise.

The binary time constant τ_2 is that interval of time during which the temperature rise comes within 1/2, or 50 per cent, of the ultimate rise. In a period of 2 τ_2, the rise will come within $1/2^2$, or 25 per cent, and in 3 τ_2 within $1/2^3$, or 12.5 per cent, of the ultimate rise.

Fig. 2, which is drawn on arith-log paper, shows the attainments and deficiencies at any number up to four exponential or binary time constants. These lines are straight. Thus after four exponential time constants, the attainment is about 0.982, or 98.2 per cent, while the deficiency is 0.018, or 1.8 per cent. Similarly, after the lapse of four binary time constants, the attainment is 0.9375 or 93.75 per cent and the deficiency $^1/_{16}$, or 0.0625 or 6.25 per cent. The two time constants are always connected by the relation

$$\tau_2 = 0.69315\,\tau_\epsilon \quad \text{or} \quad \tau_\epsilon = 1.4427\,\tau_2 \text{ hours} \qquad (1)$$

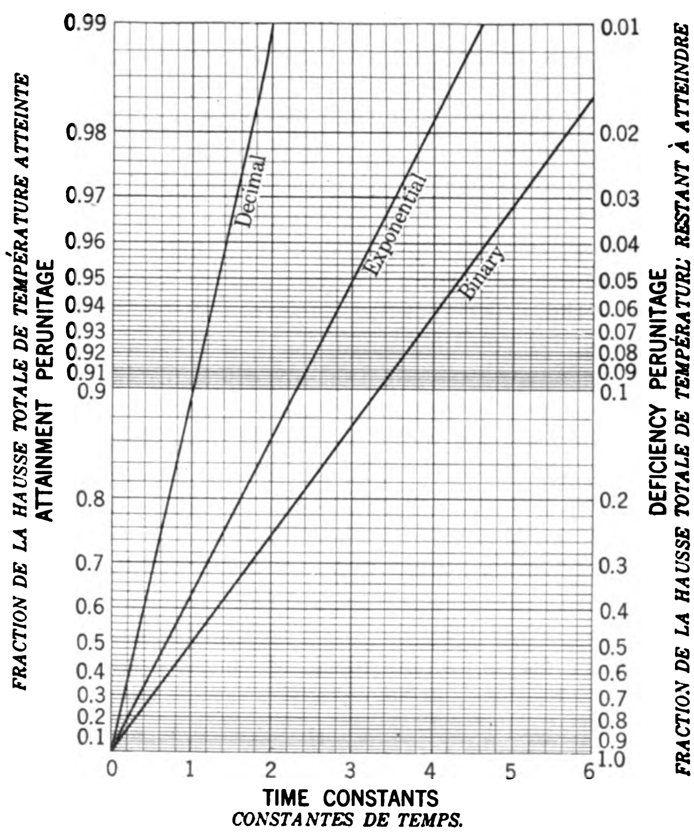

FIG. 2—ATTAINMENTS AND DEFICIENCIES IN TERMS OF THE DIFFERENT TIME CONSTANTS

so that if the exponential time constant is known, the binary constant is always approximately 70 per cent of it.

The binary time constant τ_2 of a modern rotary dynamo machine ordinarily lies between 10 minutes and 40 minutes, and does not vary greatly with the size or rating of the machine. If we take a mean value of say 25 minutes, and assume that the temperature rise of the machine element considered follows a

*Bibliography 1, 2, 5, 13, 14, 15, 17, 18.

time-constant curve, then when the load is suddenly changed from one steady value to another, the characteristic $\Theta - P$ curve enables the corresponding change in ultimate temperature rise to be predicted. Suppose that the change will be ultimately 30 deg. cent. Then in τ_2, or 25 minutes, the rise will be 15 deg. cent., in $2\,\tau_2$, or 50 minutes, it will be $15 + 7.5 = 22.5$ deg. cent., in $3\,\tau_2$, or 75 minutes, it will be $22.5 + 3.75 = 26.25$ deg. cent., and so on. After $6\,\tau_2$, or 150 minutes, the change will be for practical purposes complete.

An operating engineer may be able to utilize the time constant of a machine in an emergency. He may want to carry a temporary overload without overheating his machine. He knows that he can carry such an overload during a period of one time constant, without attaining more than half the temperature rise due ultimately to that load, provided that the element of the machine considered has this margin of temperature below the danger point, and that the curve of heating is exponential; also that no other element will rise more quickly.

Although rotary machines have binary time constants usually well below one hour, some transformers and particularly, air-cooled, oil-immersed transformers, have time constants of three or four hours. The period during which a temporary overload can be maintained with due precautions, in an emergency, is thus correspondingly increased with such transformers.

When the temperature rise of a machine or element is exponential, it becomes easy to predict the course of the changing temperature when the $\Theta - P$ characteristic and the binary time constant are given, if the load is changed abruptly from one long continued steady value to another. If the load is changed in a less simple way, so that one thermal transient is started before the preceding transient or transients have been substantially terminated, the predetermination of the corresponding temperature becomes more complex. As is well known to designers of traction motors, the resultant curve of θ against time is obtainable from the superposition of a plurality of single exponential curves.

Significance of the constants C, D and E. These variable-regime thermal constants are not at present of much use by themselves. They may, however, be useful conjointly, in arriving at an estimate of the time constant B. If the time constant can be predetermined with satisfactory precision, a $\theta - t$ test of temperature rise against time becomes unnecessary, provided that it is known that the curve is exponential, and that the ultimate rise is known from the $\Theta - P$ characteristic. The relations between B, C and E are given by the familiar formula:

$$\tau_\epsilon = k/s \qquad \text{hours (2)}$$

or

$$\tau_2 = 0.693\,k/s \qquad \text{hours (3)}$$

The value of k, or the C constant, may be computed theoretically from the weights of the different parts of a machine and their specific heats. In practise, certain empirical constants may have to be used, as in Appendix I. Consequently, a time constant that has been observed, is at present more reliable and satisfactory than a time constant that has been computed; although designers, guided by experience, place confidence in their predetermined time constants.

E. The dissipation constant s is defined by the formula

$$p = \Theta\, s \qquad \text{watts (4)}$$

where p is the power lost in the machine or element during the steady thermal state, after the ultimate rise Θ has been substantially attained. Knowing the power losses, and the ultimate temperature rise corresponding thereto, the constant s can thus be evaluated.

Tests for the Exponential Quality of $\theta - t$ Temperature Rise Curves

The time-constant of a machine can only be utilized to the degree of precision within which the temperature rise curve is exponential, according to the formula:

$$\frac{\Theta - \theta}{\Theta} = \epsilon^{-\frac{t}{\tau_\epsilon}} = 2^{-\frac{t}{\tau_2}} = 10^{-\frac{t}{\tau_{10}}} \qquad (5)$$

where $\dfrac{\Theta - \theta}{\Theta}$ is the *deficiency*, θ/Θ being the *attainment*. A temperature rise curve $\theta - t$ having been obtained by observation, it is always possible to determine, from inspection, whether the curve is in satisfactory agreement with (**5**); *i. e.*, whether it admits of time-constant application. It is first necessary that the ambient temperature during the test shall have been kept constant, or that the curve be first corrected accordingly, if it has slightly varied*. The ultimate temperature rise Θ, for the curve must also be forthcoming, either by noting that the test has been maintained for a time sufficient to develop substantially this ultimate rise, or by extrapolating from the curve as in Appendix II, or from preceding temperature-rise tests as recorded in a $\Theta - P$ characteristic.

The time during which the temperature rise θ changes from 0 to $\Theta/2$ deg. cent. is measured along the time axis of the curve. This should be the binary time constant τ_2. In another such time constant, the further temperature rise should be $\Theta/4$ degrees. In the third such time constant, the further rise should be $\Theta/8$, and so on. If these relations hold satisfactorily, the curve may be regarded as exponential, from an engineering standpoint. Strictly speaking, the theoretical requirements for exponential temperature rise are so severe, that they can probably never be fully complied with in any machine. Nevertheless, it is surprising how many machines develop satisfactory time-constant curves in their tests, although the time constant of one element, such as the field-winding, may be markedly

*Bibliography 17.

different from that of some other element, say the armature winding in the slots.

A second test, but much more severe, of the exponential quality of a $\theta - t$ curve, is to plot the deficiency $(\Theta - \theta)/\Theta$ on inverted arith-log paper. Thus Fig. 9 gives a $\theta - t$ curve for a certain 2000-kv-a. air-cooled transformer, the curve being drawn exponentially to fit the observations, according to the formula

$$(50.5 - \theta)/50.5 = \epsilon^{-\frac{t}{3.72}} = 2^{-\frac{t}{2.58}}$$

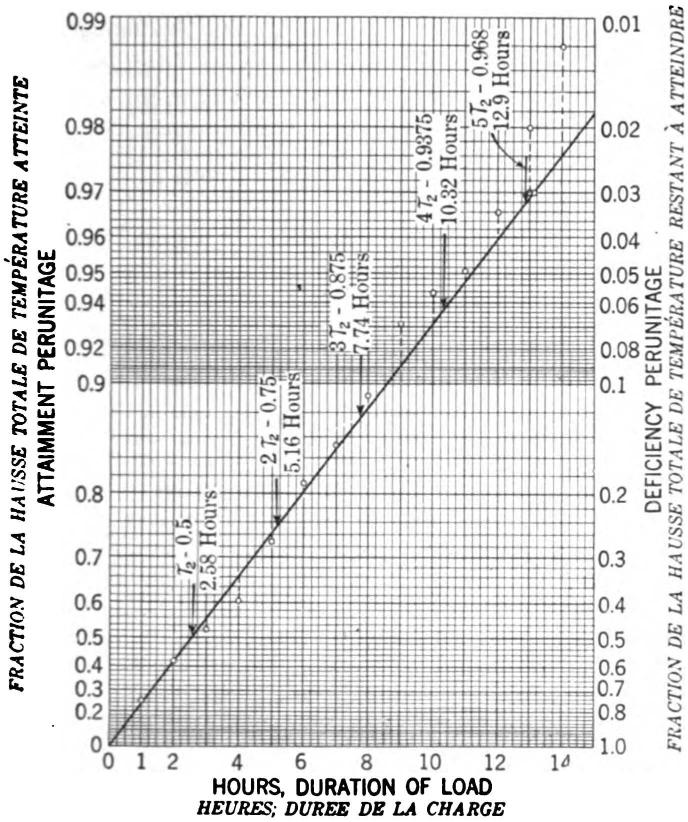

FIG. 3—TEMPERATURE-ELEVATION CURVE OF 2000-KV-A.

Transformer (Fig. 9), drawn on inverted arith-log paper. Straight line, computed exponential rise. Small circles, observed attainments and deficiencies of temperature elevation

It will be seen that the hourly observations conform to this curve satisfactorily. Fig. 3 gives the corresponding plot of the same observations on arith-log paper. The exponential curve is now a straight line; but the observations appear to depart from it much more widely, especially in the upper parts.

In cases where the temperature rise curve departs so far from an exponential law as not to admit of time-constant reckoning, it may sometimes be dealt with in a relatively simple manner by the use of two independent time-constants. Messrs. V. M. Montsinger* and W. H. Cooney† have shown that when, as in many modern air-cooled, oil-immersed transformers, the windings are thermally separated from the core, but the oil is thermally common to both, the temperature rise of the windings above the top layer of oil follows satisfactorily one exponential curve of say 3½ *minutes* binary time constant; whereas the top layer of oil in the transformer follows satisfactorily another exponential curve, of say 3½ *hours* binary time constant.

Prof. Karapetoff has recently given a theory of the temperature rise of a body containing two thermal elements in partial mutual communication.‡ The solution leads to two independent time constants, associated with two final temperature rises, two thermal capacities k_1, k_2 and dissipations s_1, s_2. By means of appropriate tests, these time-constants may be evaluated. Practical results with the method are not yet forthcoming.

EXPERIMENTAL DATA CONCERNING HEATING CURVES OF MACHINES

Figs. 4 and 5 are taken from curves published by Mr. C. M. Laffoon§ on large turbo-alternators, using imbedded temperature detectors in the armature winding. Fig. 4 shows the temperature rise of a 35 megavolt-ampere machine (35 mv-a.), under steady load, with the detectors in contact with the copper armature conductor and within the insulating cover. The curve is drawn exponentially to fit the observations and an ultimate rise of 24 deg. cent. The binary time

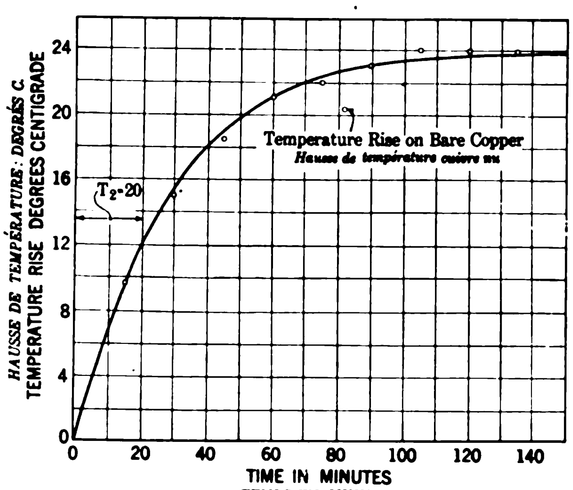

FIG. 4—TEMPERATURE RISE OF A 35,000-KV-A. THREE-PHASE TURBO GENERATOR OPERATING UNDER CONSTANT 75 PER CENT LOAD

Imbedded temperature detectors in contact with the copper winding. Curve computed exponentially to fit the small-circle observations. (C. M. Laffoon, Bibliography 18, Fig. 2).

constant is 20 minutes. The agreement of the observations with the curve is, in general, satisfactory. Fig. 5 shows similar results reported on a 25.9 mv-a. alternator armature using two different positions of imbedded detector; namely, one in contact, as before, with the copper winding, and the other between adjacent coils in the slots; so that an insulating cover separated the

*Bibliography 18, pages 649-651, also 7a.
†Bibliography 19.
‡Bibliography 23.
§Bibliography 18, pages 651, Figs. 2 and 3.

detector from the copper. In the upper curve, the agreement with observations is, in general, satisfactory, but there is a wide departure of the observed temperature rises from the exponential lower curve, during the first hour. This departure is attributable to the effects of the interposed layer of insulation between detector and copper. The time constant τ_2 of the upper curve is 26 minutes, and for the lower curve 38 minutes.

Fig. 6 gives three temperature rise curves reported by

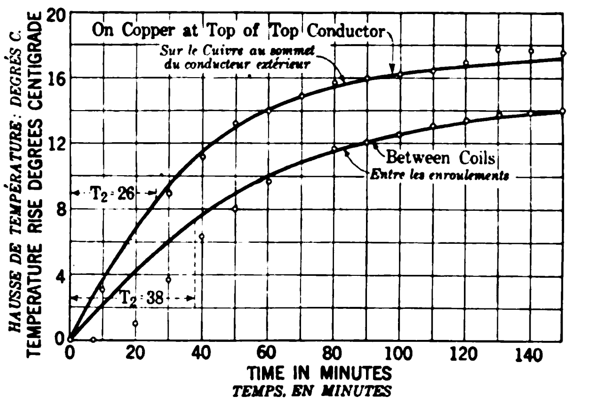

FIG. 5—TEMPERATURE RISE OF A 25,900-KV-A. THREE-PHASE TURBO GENERATOR OPERATING UNDER CONSTANT 75.3 PER CENT LOAD

Exponential curves to fit experimental data. Imbedded temperature detectors. Upper curve for detectors in contact with copper winding. Lower curve for detectors between coils, but outside insulation. (C. M. Laffoon, Bibliography 18, Fig. 3).

Mr. G. E. Luke* for a 35-h. p., d-c. railway motor. The temperature rises were obtained with imbedded thermocouples, and in the case of the armature, through slip rings. The observations conform well with the computed exponential curves. The binary time constant of

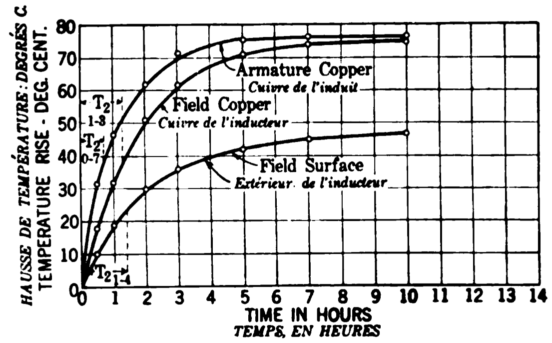

FIG. 6—TEMPERATURE-RISE CURVES OF A 35-H-P., D-C. RAILWAY MOTOR, 300 VOLTS, 35 AMPERES

Temperature by imbedded thermocouples (armature by slip rings). Curves are exponential to fit observations (G. E. Luke, Bibliography 18, Fig. 9).

the armature copper was 0.7 hour, that of the field copper, 1.3 hours, and of the field surface 1.4 hours. This shows that the location of the hottest-spot temperature in a machine during a temporary overload, may depend upon the time constants of the different elements.

In additional temperature rise tests reported by Mr. Luke, the agreement between the test observations and exponential curves was satisfactory in certain cases but unsatisfactory in others, depending upon the relative mutual dependence of the thermal elements in the structure of the machine.

Fig. 7 gives four temperature rise curves reported by M. O. E. Shirley taken in a series of special thermal tests on a 1100-kv-a., 3000-volt, three-phase synchronous motor. This machine was operated as a synchronous condenser, at substantially zero power factor, starting at ambient temperature, under steady excitation. The ambient temperature remained practically uniform throughout. The top curve represents the rotor field-winding temperature, from volt-ampere measurements. Until after the first hour, the observations conform satisfactorily well with the exponential curve of $\tau_2 = 34$

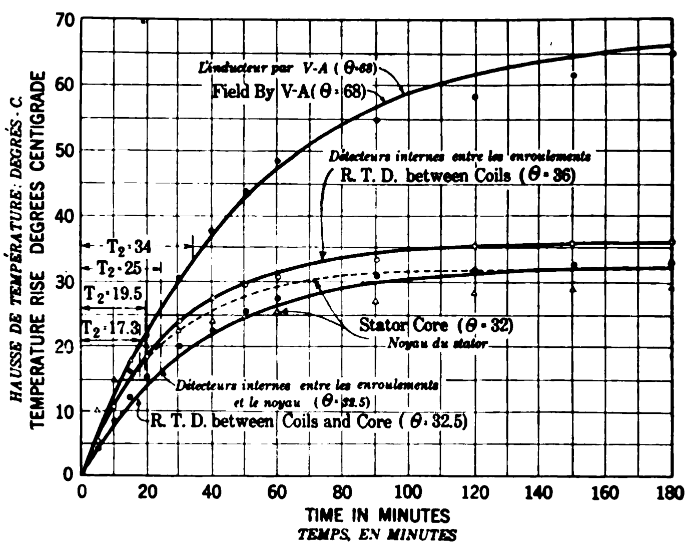

FIG. 7—TEMPERATURE-RISE CURVES FOR A 1100-KV-A., 3000-VOLT, THREE-PHASE SYNCHRONOUS MOTOR OPERATED AT APPROXIMATELY ZERO POWER FACTOR OR SYNCHRONOUS CONDENSER (O. E. SHIRLEY)

minutes. The maximum rise of this field winding exceeds the usual values on account of the over-excitation for zero power factor. The two R. T. D. curves refer to imbedded resistance temperature detectors. The upper of these curves refers to detectors between stator armature coils in the slots, and the lower to detectors placed between stator armature coils and stator core. Both of these curves are in satisfactory agreement with the observations. The former has a time constant of 19.5 minutes, and the latter 25 minutes. The stator core curve, derived from thermometer readings, is not in good agreement with the observations.

Air-cooled, Oil-immersed Transformers. Figs. 9, 10 and 11 give temperature rise curves reported by Mr. W. H. Cooney† from observations on large single-phase transformers tested under conditions of constant load. In these cases the time constant was predetermined by

*Bibliography 18, page 653, Fig. 9.

†Bibliography 19, Figs. 6, 8 and 10.

the method outlined in Appendix I. The curves are exponential with these respective time constants, and conform satisfactorily to the measured temperature rises. They refer to top-oil temperature rise above ambient air. The dissipation constant s in these

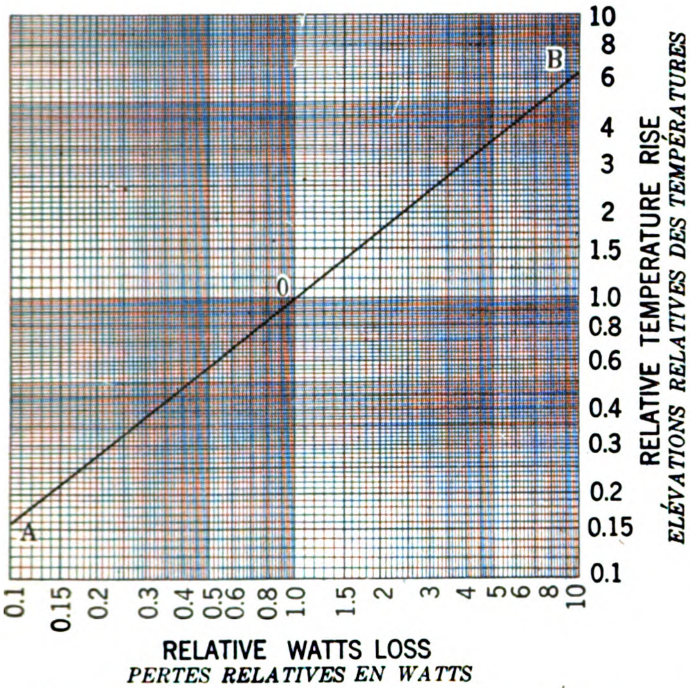

FIG. 8—APPROXIMATE STRAIGHT-LINE RELATION ON LOG PAPER BETWEEN RELATIVE TEMPERATURE ELEVATION OF TOP OIL AND RELATIVE LOSS OF POWER IN TRANSFORMER, REFERRED TO THE TEMPERATURE ELEVATION AT NORMAL RATED POWER LOSS

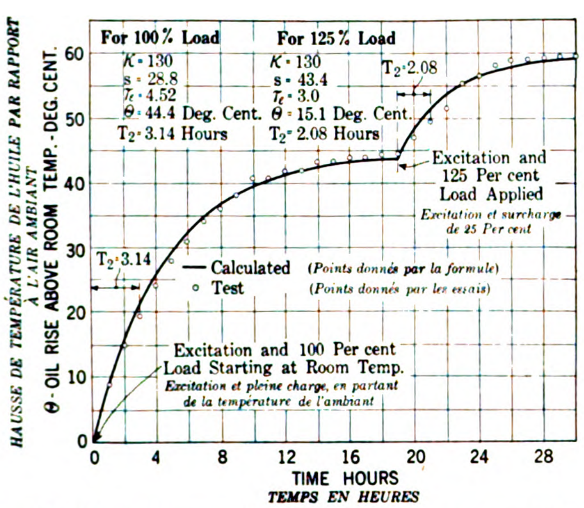

FIG. 9—TEMPERATURE RISE OF TOP OIL ABOVE AMBIENT AIR WITH TIME, IN A 75-KV-A. TRANSFORMER, 100 PER CENT LOAD AND EXCITATION APPLIED FOR 19 HOURS, FOLLOWED BY 125 PER CENT LOAD FOR 11 HOURS MORE

cases, appears not to have been constant over the temperature range. Fig. 8 gives the relation observed between temperature rise and relative watts loss, as drawn on log paper, for an exponent of 0.8. As a consequence of this variation in s, the time constant varies with the load on the transformer. Thus in Fig. 9 the first part of the curve, for 100 per cent load, during 19 hours, has $\tau_2 = 3.14$ hours, the ultimate temperature rise being 44.4 deg. cent. The second part of the curve, for 125 per cent load, during 11 hours, has $\tau_2 = 2.08$ hours, the ultimate additional temperature rise being 15.1 deg. cent., or 59.5 deg. cent. above ambient.

Fig. 10 gives a corresponding curve of temperature

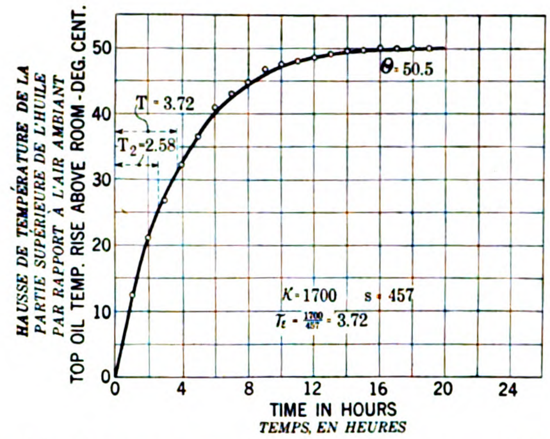

FIG. 10—TEMPERATURE RISE OF TOP OIL IN A 2000-KV-A. AIR-COOLED, OIL-IMMERSED TRANSFORMER STARTING UNDER NORMAL LOAD AND EXCITATION FROM AMBIENT ROOM TEMPERATURE

Exponential curve computed to fit observations. (W. H. Cooney, Bibliography 18, Fig. 8).

rise in a 2-mv-a. air-cooled transformer, operated for 19 hours under normal load conditions. The thermal capacity is given as 1700 watt-hours per deg. cent., and the dissipation constant 457 watts per deg. cent., so

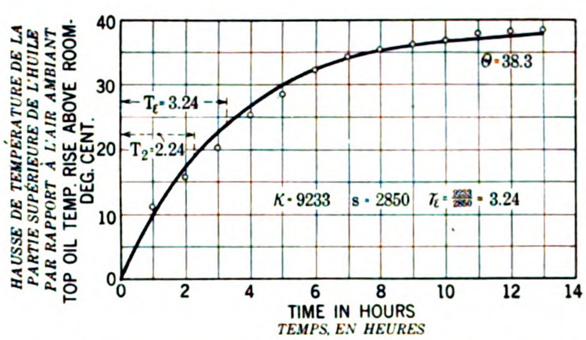

FIG. 11—TEMPERATURE RISE OF TOP OIL IN A 12,500-KV-A. AIR-COOLED, OIL-IMMERSED TRANSFORMER, STARTING UNDER NORMAL LOAD AND EXCITATION FROM AMBIENT ROOM TEMPERATURE

Exponential curve computed to fit observations. (W. H. Cooney, Bibliography, Fig. 10).

that the exponential time constant τ_ϵ is 3.72 hours, and the binary time constant 2.58.

The curves in Fig. 11 refer to the case of a 12.5-mv-a. transformer, with a thermal capacity of 9233 watt hours per deg. cent.

In all of the cases represented in Fig. 9, 10 and 11 the time constants were computed from the dimensions and weights of the transformer elements. The exponen-

tial curves were then drawn according to these time constants so as to show the conformity or departure of the observed temperatures from the curves.

Conclusions

The cases presented in Figs. 4 to 11 indicate that various examples of different types of machines follow temperature rise exponential curves, under steady load, within limits of precision sufficient for many practical purposes. On the other hand, there are various machines which, either in whole or in certain elements, depart materially from such curves. It is, therefore, unsafe to assume that any or every machine, taken at random, will follow an exponential temperature rise curve, unless either a test or record of the machine will establish the fact.

The binary time constant of a machine in association with its ultimate temperature rise characteristic curve, will enable the thermal behavior of the machine to be predicted in the variable regime, under change of steady load.

It is desirable to study the temperature-rise curves of all classes of machines, in order to diffuse a general knowledge of their behavior in the variable regime, this being useful information for the operating engineer.

Appendix I

Montsinger-Cooney Method of Estimating Thermal Capacity of Air-cooled Oil-immersed Transformers

Data for thermal capacity of transformer from top-oil to exterior ambient temperature.

Sp. heat of copper wire 0.0935

Sp. heat of steel core 0.115

Sp. heat of oil 0.47

Spec. thermal capacity of copper wire 0.109 watt-hr./kg. and deg. cent.

Spec. thermal capacity of steel core 0.134 watt-hr./kg. and deg. cent.

Spec. thermal capacity of oil 0.462 watt-hr./liter per deg. cent.

The ratio of mean oil temperature to top-oil temperature varies with the form and size of the oil tanks, but an average value is 0.86. Applying this ratio, the mean specific thermal capacity of the tank oil is $0.462 \times 0.86 = 0.397$, or in round numbers 0.4 watt-hr./liter deg. cent.

The weight of steel core in a transformer is commonly about 5.5 times that of the copper wire. Applying this ratio to the total metal in the transformer, the average specific thermal capacity of that metal is

$$\frac{0.109 \times 1 + 0.134 \times 5.5}{6.5} = 0.13 \text{ watt-hr./kg. and}$$

deg. cent.

Different parts of the oil tank attain different temperature elevations. Experience shows that a ratio of $2/3$ may be applied to the weight of steel in the tank in estimating, its specific thermal capacity.

The thermal capacity of the entire transformer from the top oil to the external ambient temperature is then

$$k = 0.13 \text{ (kg. copper + kg. core + } 2/3 \text{ kg. tank)} + 0.4 \text{ (liters oil)} \quad \text{watt-hr. per deg. cent.}$$

Data for thermal capacity of winding with respect to top oil:

$$k' = 0.109 \frac{S + s'}{2\,S'} \times \text{kg. bare copper wire} \quad \text{watt-hr./deg. cent.}$$

where S is the cross-section of the insulated wire and s' is the cross-section of the bare wire

This formula for k' takes account of the specific heat of the insulation of the wire as well as that of the wire itself.

Example of Time-Constant Computation

Data for 100 per cent load and excitation.

Top-oil steady temperature elevation, 40 deg. cent.

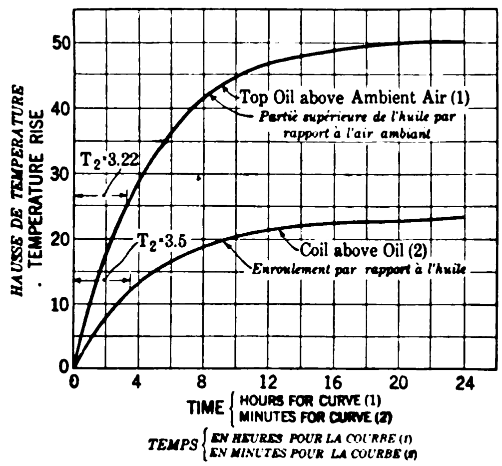

Fig. 12—Computed Temperature Elevation Time Curves for Transformer Having the Constants Analysed in Appendix I

Abscissas minutes for curve 2 coil rise above oil, and hours for curve 1 top oil above air

Winding steady temperature elevation, above top oil, 15 deg. cent.

Copper loss 9000 watts.

Core loss 6000 watts.

Weights, steel tank 2040 kg.

Steel core 1900 kg.

Copper 450 kg.

Volume of oil, 3410 liters.

Required the time constant for 125 per cent load and excitation, starting from ambient temperature.

Final copper loss $(1.25)^2 \times 9000 =$	14060 watts
" iron "	6000 "
Total, neglecting changes in resistance,	20060 watts

$$\Theta_0 \textit{ for top oil.} \quad \text{Relative losses } \frac{20060}{15000} = 1.337$$

From Fig. 1, oil rise $= 1.26 \times 40$ deg. cent. $= 50.4$ deg. cent.

$k_2 = 0.13\,(450 + 1900 + 2 \times 2040/3) + 0.4 \times 3410 = 1850$ watt hr./deg. cent.

$s_2 = 20060/50.4 = 398$ watts/deg. cent.

$$\tau_\epsilon = \frac{k_2}{s_2} = \frac{1850}{398} = 4.65 \text{ hours.}$$

$\tau_2 = 0.693 \times 4.65 = 3.22$ hours.

Θ for copper above top oil

$$15 \times (1.25)^2 = 23.5 \text{ deg. cent.}$$

$k_\epsilon' = 454 \times 0.109 = 49.5$ watt-hr./deg. cent.

$s' = 14060/23.5 = 508.3$ watts/deg. cent.

$$\tau_\epsilon = \frac{k'}{s'} = \frac{49.5}{508.3} = 0.083 \text{ hour} = 5.0 \text{ min.}$$

$\tau_2 = 0.693 \times 0.0826 = 0.057$ hour $= 3.5$ min.

The exponential curves for θ_0 and θ_c are given in Fig. 12, as computed from the above data, together with their binary constants, to two different scales of time, as abscissas.

The original data from which Appendix I has been prepared, will be found in Bibliography 18 and 19.

Appendix II

FORMULA FOR DERIVING THE ULTIMATE TEMPERATURE RISE FROM AN INCOMPLETE TEMPERATURE RISE—TIME CURVE ASSUMED TO BE EXPONENTIAL.*

$$\Theta = \frac{\theta_1}{2 - (\theta_2/\theta_1)} \quad \text{deg. cent.}$$

where θ_1 is the temperature rise at the end of t_1 hours, and θ_2 is the corresponding temperature rise at the end of $t_2 = 2\,t_1$ hours. It is assumed that $\theta = 0$ at the start, and that the ambient temperature remains constant throughout.

Thus if $\theta_2 = 1.5\,\theta_1$, it will follow that $\Theta = 2\,\theta_1$ and $t_1 = \tau_2$.

FORMULA FOR COMPUTING THE BINARY TIME CONSTANT FROM TWO ORDINATES OF AN EXPONENTIAL TEMPERATURE RISE CURVE TAKEN AT TWO SUCCESSIVE EQUAL INTERVALS OF TIME FROM THE START.

$$\tau_2 = \frac{0.30103\,t_1}{\log\left(\frac{\theta_1}{\theta_2 - \theta_1}\right)} \quad \text{hours}$$

where θ_1 is the temperature rise after t_1 hours, and θ_2 the corresponding temperature rise after $t_2 = 2\,t_1$ hours. Thus if $\theta_2 = 1.5\,\theta_1$ $\quad \tau_2 = t_1$

LIST OF SYMBOLS EMPLOYED

Temperature Rise and Losses in Solid Structural Steel

Exposed to the Magnetic Fields from A-C. Conductors

BY O. R. SCHURIG*
Member, A. I. E. E.

and

H. P. KUEHNI*
Non-member

Synopsis.—*Experimental investigations were made for the determination of the temperature rise and the losses occurring in structural steel members exposed to the fields from a-c. conductors. The work originated from the demand, among the designing engineers of an electrical manufacturing company, for practical data which would enable them to estimate, at least roughly, the temperature rise and the heat losses in the more common cases of structural steel members passing near the conductors. In the paper presented here, are given the results of the investigations in question. Examples are given illustrating the method of procedure in estimating temperature rise and losses in structural steel. The method of calculation applied is, in most cases, empirical. The major factors affecting temperature rise and losses are discussed on the basis of the test data. An understanding of these factors will often permit a designer to avoid iron heating without sacrifice of space or of economy. Thus a good part of the data presented applies to cases for which the temperature rise of the steel would ordinarily be considered not seriously objectionable.*

INTRODUCTION

In electric stations heavy a-c. conductors are often run in close proximity to steel structural members. It is well known that the steel members when exposed to a-c. magnetic fields will tend to heat on account of induced eddy currents and hysteresis losses. While a local temperature rise of a few degrees here and there in the steel will generally not be seriously objectionable, the iron losses must not reach an amount sufficient to raise materially the ambient temperature in the vicinity of the conductors themselves or in the vicinity of other electrical apparatus. Moreover undesirable expansion of the building steel and cracking of the concrete may sometimes result from excessive heating of the steel. It is even possible that, unless consideration is given to the iron losses, they may seriously add to the station losses.

While all of the above matters have been known, at least qualitatively, there has been but a scant amount of data available for designers to estimate the temperature rise and the losses in question.

OBJECT AND SCOPE OF PAPER

Since there has been an increasing demand for data on heating and losses in solid structural steel, especially in view of the more frequent use of the isolated-phase system of station layout, with its more wide-spread stray magnetic fields, an experimental investigation was made by an electrical manufacturing company to obtain, for their designers and engineers, practical data on the temperature and the losses in a number of the more common cases of structural steel members passing in the vicinity of heavy-current, a-c. conductors. Actual measurements of temperature rise and of losses on full-size steel members were made in the laboratory. Naturally only a limited variety of structural arrangements could be represented. Nor was it possible to set up a general or fundamental formula, for practical use, for the calculation of the temperature rise of solid iron members. Hence the application of

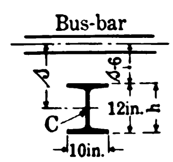

FIG. 1

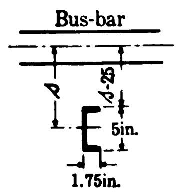

FIG. 2

FIGS. 1-2—TEST POSITIONS OF IRON MEMBERS (*I*-BEAM AND CHANNEL BEAM)

With respect to conductor crossing at right angles to the iron

the results obtained is primarily limited to the range of conditions covered by the tests. Nevertheless, it has been possible, by suitable choice of test conditions, to obtain a considerable amount of useful data, which

With respect to a straight conductor passing through the frame at right angles to its plane

have been effectively applied for a year or more, in practical cases of station steel design and of conductor layout. The principal results obtained are summarized in the following paper. No recommendations are made, however, concerning the safe permissible temperature rise of the steel members or the maximum allowable losses.

Abridgment of paper presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies available upon request.

Method of Test

The iron structural members to be tested—in most cases full-size pieces—were placed in a variety of positions with respect to heavy-current test circuits. In a good many of the tests, isolated-phase construction was simulated by having the return conductors relatively remote from the samples under test, so that the simple case of one infinitely long, straight conductor, with the return conductor infinitely remote, was closely approached. In other tests, the resultant field at the

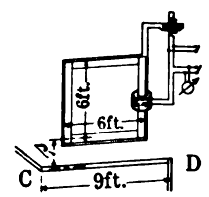

Fig. 6—Test Arrangement of "Electric Loop" Consisting of a 6-ft. by 6-ft. Channel Iron Frame

Conductor *C D* being in the plane of the frame

iron member under test, due to all conductors in the circuit, had to be considered. Moreover, in some circuit arrangements the adjacent-phase construction was deliberately imitated. The effects of conductor bends and loops on nearby iron members was also investigated. All tests were made at an ambient temperature of from 20 to 25 deg. cent.

For the I-beam, channel beam, switchboard pipe, round reinforcing rods and steel plates tested the resistivity ranged from 13.2 to 15.9 microhm-cm., and the maximum permeability from 1210 to 1800 at densi-

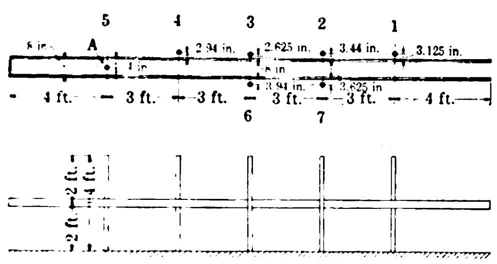

Fig. 7—Conductor and Iron Pipe Layout in Iron Heating Tests

With pipes passing outside of conductor group as well as between going and return conductors in adjacent-phase circuit

ties of from 6200 to 7800 gausses. In so far as structural steel members are concerned (having values of resistivity and permeability within the range of those given) approximate estimates of temperature rise may therefore be made on the basis of the test data given here (in accordance with the procedure outlined in the examples below), without further consideration of permeability and resistivity.

The temperature measurements were made with mercury thermometers attached with putty to the iron samples under test, or by thermocouples in the case of some of the smaller samples such as reinforcing rods.

In most cases the sustained final temperatures, or temperature rise, of the steel for constant loads were obtained.

The currents in the test circuit were of substantially sine-wave shape at frequencies of either 60, 40 or 25 cycles per sec. and were as high as 5800 r. m. s. amperes.

In a number of cases loss measurements were made. The method was to obtain the total input into the busbar system and to subtract therefrom the copper losses. A sensitive wattmeter of the reflecting dynamometer type was used whose current coil was connected to the line-current transformer and whose potential circuit was connected to two points of the busbar system embracing all the flux which produces losses. The copper losses were measured separately in the absence of the iron members. The measurement of a known loss (of the order of magnitude of the iron losses) produced

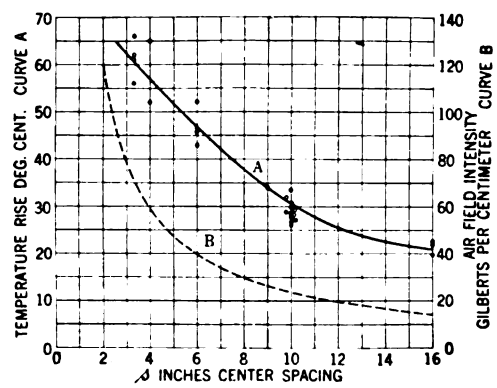

Fig. 8—Temperature Rise vs. Spacing (Curve A)

For long straight bare structural iron members crossing at right angles to a straight 3000-ampere, 60-cycle conductor, return conductors remote

Curve A: Final maximum temperature rise at iron hot spot for a constant conductor current

Curve B: Air field intensity vs. spacing for a single 3000-ampere straight long conductor

Center spacing measured from center of conductor to center of iron member

by a current induced in a short-circuited coil by the flux from the busbar circuit showed an over-all accuracy of loss measurements of better than 10 per cent.

Short-circuited copper windings of one or more turns were placed around the iron member in several cases so as to embrace the flux passing through the iron member and thus to reduce the iron loss. Measurements of the circulating current in the short-circuit windings were made for the purpose of obtaining a relation between iron heating (and losses) and the ampere turns in the short-circuited copper.

RESULTS OF TESTS

I. Straight Magnetic Members

Effect of Current on Temperature Rise

The final temperature rise at the surface of the steel member at the point nearest to the conductor, was found to vary as the 1.7th power (average value) of the conductor current for thick steel members (thicker than, say 1/8 in.) crossing at right angles to a conductor. The

value given is an average exponent derived from test results covering a current range from 1000 to 5800 amperes, center spacings between conductor and iron member from 2.5 to 16 in., and values of iron temperature rise from 10 to 175 deg. cent. Values of the exponent obtained from the various tests ranged from as high as 2 (for low values of maximum flux density and temperature rise) to 1.4 (for the highest values of temperature rise tested).

Temperature Rise at Different Spacings for Straight Iron Member Crossing at Right Angles to a Single Straight Conductor

The effect on temperature rise of spacing alone, in the absence of material effects of return conductors, is indicated in Fig. 8, for the case of a long, straight 3000-ampere, 60-cycle conductor crossing at right angles to a long, straight, horizontal, bare, solid, structural iron member. (It will be shown later that the shape and size of the iron member within certain limits, do not materially affect the hot-spot temperature rise for a given center spacing and current). All spacings are from center of conductor to the center of the iron member.

According to Fig. 8 it is seen that increasing the spacing from 6 to 10 in. reduced the maximum temperature rise of the iron 35 per cent, a further increase of spacing to a total of 16 in. gave a temperature rise about half that for the 6-in. spacing.

Effect of Frequency on Temperature Rise

Tests for temperature rise at 25, 40 and 60 cycles per sec. gave values of temperature rise roughly in the ratio of 1, 1.3, and 1.6, currents and center spacings being the same. The tests were made on 1¼-in. standard switchboard bare iron pipes and on bare ½-in. round and ½-in. square iron reinforcing rods.

Effects of Size, Shape, and Thickness on Temperature Rise

Various kinds of straight iron members crossing at right angles to a conductor, and not less than, say ⅛ in. thick and of cross-sectional dimensions (in a direction perpendicular to the conductor as dimension h in Fig. 1) up to 12 in. at *center spacings* from 10 in. to 16 in. from the conductor, had substantially equal values of temperature rise at any given busbar current, as indicated by tests of the following iron members: 12-in. by 10-in. I-beam, 5-in. by 1¾-in. channel beam, 4-in. by ⅜-in. by 8-ft. steel plate, 10-in. *I*-beam flange,* 1¼-in. switchboard steel pipe. See Fig. 9. In other words, the temperature rise under these conditions was *independent of the size, or cross-sectional area or shape for a given center spacing between conductor and iron,* regardless of the distance from the conductor to the nearest part of the iron. Variations of temperature rise within this rule were found to be not higher than 30 per cent and usually much less.

*Cut from the 12 in. I-beam already mentioned.

If the iron members have a thickness of the order of, or less than, two or three times the equivalent depth of flux penetration* (calculated for relatively thick members), or say less than ⅛ in., it will have a smaller temperature rise than thicker iron members because a smaller volume of iron per unit of surface will participate in the production of loss as indicated in Fig. 9.

Effect of Fields from Several Conductors on Temperature Rise of Iron

In a great many practical cases, there is more than one conductor contributing to the field at the hot spot of the iron. A number of such cases were tested and the following approximate rulings for iron heating were obtained when the "air-field intensity" along the axis of the iron member was taken into account. By "air field intensity" is meant the calculated resultant intensity, due to all conductors, in air assuming no magnetic bodies present, the intensity for the present

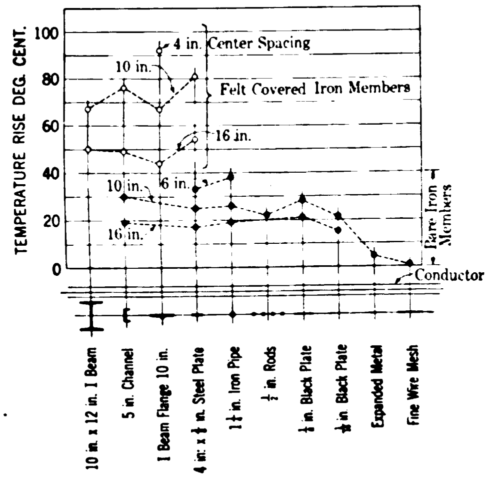

Fig. 9—Comparison of Values of Maximum Temperature Rise

For different iron members crossing at right angles to conductor
Iron members horizontal

Figures on plot indicate center spacing between conductor and iron members

purpose being calculated along the line of the longitudinal center axis of the iron member at the section through the hot spot, *i. e.*, usually at the point where the axis is at the shortest distance from the nearest conductor. The relations pertaining to the effects of the magnetic fields from several conductors on temperature rise in solid iron are:

a. At any given center spacing from iron member to nearest conductor, the hot-spot temperature rise varied as the 1.4 to the 2.0 power (see Table I) of the air field intensity calculated for the center point of the cross section nearest to the conductor, as for instance, point C in Fig. 1—a relation similar to that already given for the current.

*Bibliography 2.

TABLE I

VALUES OF EXPONENT n, IN EQUATION (1) FOR CALCULATION OF TEMPERATURE RISE OF SOLID STRUCTURAL IRON MEMBERS CROSSING AT RIGHT ANGLES TO CONDUCTORS

H r. m. s. gilberts per cm. air field intensity.	n
20 or less	2.0
50	1.7
100	1.5
150	1.4

b. An approximate relation useful in a variety of cases for estimating the temperature rise of iron members exposed to fields from more than one conductor was found to be the following: at any given center spacing between an iron member and the conductor contributing the major component of the resultant field (usually this is the conductor passing nearest to the iron) the maximum hot-spot temperature rise, for any particular value of air field intensity (due to all conductors), at the center of the iron section through the hot spot, was independent of the arrangement of conductors—within certain limits.

A material departure from rule (b) was found, as would be expected, for those cases in which the different arrangements of conductors involved considerable changes in the distribution of the m. m. f. along the iron member (*i. e.*, on either side of the hot spot.) Thus for iron members outside the loop of Fig. 7, such as pipes No. 3 and 6, the experimental values of temperature rise were from 20 to 30 per cent less than those estimated from rulings *a* and *b* above, the reduction allowing for the fact that in the cases in question the m. m. f. and hence the iron losses fall off much more rapidly along the iron (*i. e.*, on one or on both sides of the hot spot) than the m. m. f. and the losses in a steel member crossing at right angles to *one* straight conductor only, center spacings being equal.

IRON MEMBERS RUNNING PARALLEL TO CONDUCTOR

A long and narrow steel member, such as an I-beam, a channel, or a pipe, will ordinarily heat much less (from 30-80 per cent less in the cases tested) when running parallel to the conductor than when crossing it at right angles, for the same spacings and currents. This is because the iron portion of the flux path around the conductor is a much smaller part of the complete flux path than in the case of a steel member crossing at right angles to the conductor. It will, therefore, often be advantageous from the standpoint of iron heating to lay out stations with the conductors parallel rather than at right angles to the iron members.

LOSSES IN STRAIGHT IRON MEMBERS CROSSING AT RIGHT ANGLES TO CONDUCTORS

A few loss measurements were made to indicate their general order of magnitude in a few cases, and their relation to the current magnitude, frequency, to the cross-sectional dimensions of the solid iron members, and to the spacing between iron and conductor. A complete investigation of losses to cover the wide field of the many customary structural layouts was, however, not made.

EFFECT OF FREQUENCY ON LOSSES

The relation between frequency and total loss in iron was investigated in the case of a closed iron ring 4-in. wide, ¼-in. thick and 20-in. average diameter. The results of the loss measurements, at 25, 40 and 60 cycles per sec., show that the loss varied roughly as the square root of the frequency.

EFFECT OF CURRENT ON LOSSES

Loss measurements at currents ranging from 1500 to 3000 amperes were made for a 10-in. by 12-in. steel I-beam, a 5-in. by 1¾-in. channel, a 4-in. by ⅜-in. steel plate, and a 1¼-in. standard switchboard iron pipe, when passing at right angles to a straight

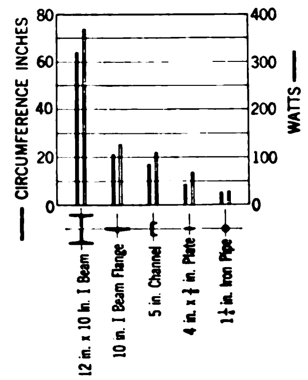

FIG. 10—COMPARISON OF TOTAL IRON LOSS WITH CROSS-SECTIONAL PERIMETER OF VARIOUS IRON MEMBERS CROSSING AT RIGHT ANGLES TO CONDUCTOR

Each iron member was tested separately
Center spacing between iron member and conductor 10 in.
Test current 3000 amperes at 40 cycles per sec.

conductor. The losses for the I-beam varied as the 1.8 to 1.9 power of the current, at constant spacing from the conductor. For other samples tested, this exponent was as low as 1.6

EFFECTS, ON LOSSES, OF CROSS-SECTIONAL AREA CIRCUMFERENCE AND SHAPE OF SOLID IRON MEMBERS

For iron members crossing at right angles to a conductor and not less than ⅛ inch thick and of cross-sectional dimensions (in a direction perpendicular to the conductor such as dimension h in Fig. 1) up to 12 in, at any given center spacing within the range from 6 to 16 in., the iron losses at any given current were actually found by test (see Figs. 10 and 11) to vary only with the circumference of the iron section and not with its area for the following iron members tested: 12-in. by 10-in. I-beam, 5-in. channel iron, 1¼-in. iron pipe, 4-in. by ⅜-in. steel plate, 10-in. I-beam flange.* Moreover, at any given spacing and conductor current, the loss for these iron members when crossing at right angles to a conductor was approximately proportional

to the circumference of the iron cross section, as indicated in Figs. 10 and 11. Deviations from this rule were less than 30 per cent (based on the average of the measured values) for the iron members tested. This result is in good agreement with the behavior of solid iron plates in respect to flux penetration and eddy-current loss, as worked out by previous investigators.†

Effect of Spacing

The relation between loss and spacing for straight iron members crossing at right angles to a straight conductor is indicated in Fig. 11. The curves show the average total measured loss per inch length of cross-sectional perimeter for center-spacings from 4 in. to

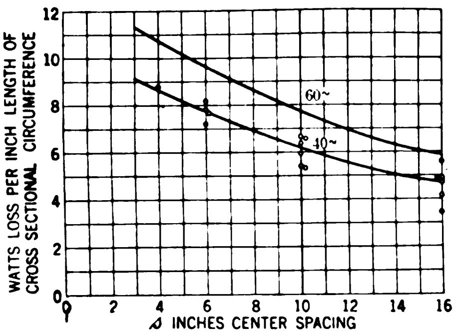

Fig. 11—Iron Loss per Inch Length of Iron Cross-Sectional Perimeter vs. Spacing

Test circuit closely approaching, as far as iron heating and losses are concerned, the arrangement of a single, long, straight conductor crossing at right angles to a straight long iron member. Busbar current 3000 amperes

Center spacing s measured from center of conductor to center of iron member

16 in. from a 3000-ampere conductor at 40 cycles and at 60 cycles.

II. Closed Iron Loops Around Conductor

Temperature Rise

To simulate *large frames of structural steel,* the circuit arrangements of Figs. 3, 4 and 5, with a 6-ft. by 6-ft. square frame of four 5-in. by 1¾-in. structural channel irons riveted or bolted together at the corners, were tested at busbar currents ranging from 1500 to 3000 amperes. The results of these tests showed that the temperature rise of iron beams in *large* rectangular magnetic frames surrounding a straight conductor and having sides larger than, say, 5 ft. may be calculated separately for each individual beam disregarding the other three sides of the frame, even if the conductor passes near the corner at a point as close as 8 in. from the nearest part of each of the two adjacent sides.

Small Frames. Both calculations and experimental observations indicate that small, closed uniform magnetic frames having sides of the order of, say, 2 ft. or less when surrounding a conductor must be expected to heat considerably more than a single straight iron member passing at right angles to a conductor, for equal spacings.

*Cut from the 12-in. I-beam already mentioned.

†Bibliography, 2, 5, 7.

Ducts of Iron Enclosing a Straight Conductor

In order to demonstrate experimentally that relatively high values of temperature rise and of loss may be obtained for sheet iron ducts completely enclosing an a-c. conductor, a horizontal 18-in. by 18-in. square iron duct of annealed iron sheets ⅛ in. thick was tested and gave a maximum temperature rise of 78 deg. cent. at the iron for a 3000-ampere, 40-cycle‡ busbar current, and an iron loss of 600 watts per foot of duct length.

Replacing the two horizontal iron sheets of the duct by non-magnetic sheets, but retaining the two iron side sheets, reduced the maximum temperature rise of the iron to 20 per cent; the total iron loss was reduced to about 10 per cent.

III. Closed Iron Frames Parallel to Conductor

The circulating current in a 6-ft. by 6-ft. channel iron frame as shown in Fig. 6 was of the order of 100 amperes when a straight 3000-ampere conductor was run parallel to one side of the frame and at 10 inches center spacing from the nearest channel iron, the conductor being outside the frame but in the same plane with it. The temperature rise of the iron was negligible. While the observed current in the 6-ft. by 6-ft. frame was small, considerably larger currents of, say, several hundred amperes may flow in heavy structural-iron frames of isolated-phase stations when the iron loops are large (say 15 or 20 ft. on a side) and especially when a heavy-current bus follows two sides of the frame§ or when the flux linking the iron loop is materially increased by the effects of other conductors. However, on account of the large surface over which the losses due to circulating currents in closed frames of large structural beams are distributed, their temperature rise will commonly be of minor consequence.

Copper Short-Circuit Rings

To Reduce Heating in Magnetic Members Crossing at Right Angles to Conductor. Copper loops around iron members crossing at right angles to heavy-current conductors may be used effectively to reduce the losses and temperature rise of the iron members; but when

‡60-cycle values of temperature rise and losses approximately 20-30 per cent higher.

§The circulating currents may be estimated for the more common types of frames if the magnitudes and relative phases of the currents in the nearby conductors, the dimensions of the frame and its position with respect to the conductors are known. The calculation in question involves determining the mutual inductance between the frame and the conductors, the self inductance and the skin-effect resistance of the frame. For skin-effect resistance calculations the reader is referred to Bibliography 2. From the loss, determined by the circulating current and the effective frame resistance, the order of magnitude of the temperature may be obtained from loss vs. temperature rise relations such as those given in Bibliography 12.

designed with too small a current-carrying capacity the copper loops may themselves seriously overheat.

In two typical cases, one with an iron girder beam 10 in. by 12 in., another with a 1¼-in. iron pipe, a copper sleeve or short-circuit winding having an ampere-turn capacity of 30 per cent of the busbar current reduced the iron losses and temperature rise to less than 10 per cent of their original values. In both cases the center spacing between the busbar and the iron member (crossing at right angles to the busbar) was of the order of from 6 to 10 inches, the busbar current ranging from 1500 to 3000 amperes.

EXAMPLES

Example 1. Estimate the hot-spot temperature rise of a square, vertical, bare channel-iron frame, having 6-ft. sides consisting of 5-in. by 1¾-in. bare channels, when a 3000 ampere, 60-cycle conductor passes at right angles through the plane of the frame at a point 10 in. above the center of the lower horizontal channel (Fig. 4), the frame being placed so that the channel section through the hot-spot is located as shown in Fig. 2 with respect to the conductor, s being 10 inches.

In estimating the hot-spot temperature rise it will be remembered that in large frames of this kind the maximum temperature is not affected by the presence of the three channel iron sides A B C; in other words the hot-spot temperature rise may be estimated by following the procedure given for single straight iron members.

Accordingly the first step is to obtain the reference temperature rise $T\,R_r$ from Fig. 8 for a straight horizontal iron member crossing at 10-in. center spacing from a long, straight 3000-ampere, 60-cycle conductor. Thus

$$T\,R_r = 31 \text{ deg. cent.}$$

and

$$H_r = 23.6 \text{ gilberts per cm.}$$

Calculating H, the air field intensity for $s = 10$ in. at the center of the channel section through the hot spot, the value

$$H = 24.8 \text{ gilberts per cm.}$$

is obtained, the excess of H over H_r being due to the effects of the return conductors in the circuit in question. Then the hot-spot temperature rise in the channel is found from*

$$\frac{T\,R}{T\,R_r} = \left(\frac{H}{H_r}\right)^n \qquad (1)$$

Where n in this case is 1.85, interpolated from Table I. Substituting the values

$$T\,R = 31\left(\frac{24.8}{23.6}\right)^{1.86} = 31 \times 1.095$$

Hence

$$T\,R = 34 \text{ deg. cent.}$$

*Based on relations (*a*) and (*b*) established above under the heading "Effect of Fields from Several Conductors on Temperature Rise of Iron."

i e., the desired final hot-spot temperature rise for a constant 3000-ampere current is estimated to be 34 deg. cent.

The nearest test condition to compare with this calculated result is a 40-cycle, 3000-ampere test with the frame of Fig. 4 and the same circuit, which test gave a 40-cycle, hot-spot temperature rise of 29.5 deg. cent. by thermometer. Estimating from the calculated 60-cycle temperature rise of 34 deg. cent., the corresponding 40-cycle temperature rise by the relation:

$$\frac{T\,R \text{ at 40 cycles}}{T\,R \text{ at 60 cycles}} = \frac{1.3}{1.6}$$

a 40-cycle value of $\dfrac{34}{1.23} = 28$ deg. cent. is calculated, which is in good agreement with the test value of 29.5 deg. cent.

Example 2. Estimate the loss in a structural 12-in. by 10-in. I-beam placed as shown in Fig. 1 with respect to a long straight conductor crossing at right angles to the beam. Let

s = 16 in.
I = 2600 amperes
f = 60 cycles per sec.
P = 64 in.

From Fig. 11, at $s = 16$ in.

$L_0 = 5.9$ watts per inch length of perimeter for a 3000 ampere reference current. Then the total loss at $I = 2600$ amperes is estimated from

$$L = P\,L_0\left(\frac{I}{I_r}\right)^n \qquad (2)$$

where $n = 1.75$, an average value. Hence

$$L = 64 \times 5.9 \times \left(\frac{2600}{3000}\right)^{1.78} = 295 \text{ watts}$$

Thus the total loss in the I-beam is estimated at 295 watts. The loss measured at 40 cycles per sec. with 2600 amperes was 230 watts, which is in good agreement with the estimated 40-cycle value of $\dfrac{295}{1.25} = 235$ watts.

SYMBOLS

f frequency, cycles per sec.

H r. m. s. gilberts per cm. in air, resultant air field intensity, due to all conductors, in the absence of iron members, calculated at the point occupied by the center of the iron cross section through the hot spot and in the direction of the longitudinal axis of the iron.

H_r r. m. s. gilberts per cm. reference air field intensity at spacing s inches from a long straight 3000-ampere conductor.

I r. m. s. amperes, conductor current for which iron heating or losses are desired.

I_r r. m. s. amperes, reference current of 3000 amperes flowing in a long straight conductor.
L watts total loss in solid iron member.
L_0 watts loss per inch length of perimeter P, for reference current I_r and spacing s.
n exponent of current or of air field intensity in temperature-rise calculations by equations (**1**) or (**2**).
ω $= 2\pi f$.
P inches perimeter of cross section of solid iron member.
ρ ohm-cm. resistivity of solid iron.
s inches, center spacing between iron member and nearby conductor.
TR deg. cent. hot-spot temperature rise at solid iron for current I and spacing s.
TR_r deg. cent. reference temperature rise at spacing s for current I_r.

SUMMARY

1. Results are given of measurements of temperature rise and of losses in structural steel I-beams, channels, pipes, plates, ducts and of temperature rise in rods, sheets and meshes when the iron members were exposed to the fields from 60-cycle, 40-cycle or 25-cycle conductors carrying currents as high as 5800 amperes. Experimental data were obtained to serve as a basis for designing copper sleeves to minimize heating and losses in structural-iron members crossing at right angles to conductors. Special tests were made on riveted and bolted steel frames placed within the field from a high-current circuit simulating isolated-phase construction. Empirical data and a simple procedure are given in the paper for estimating the temperature rise of straight steel members exposed to the magnetic fields from more than one conductor.

2. Iron members passing between going and return conductors in adjacent-phase layouts may reach very high temperatures; on the other hand, iron members passing at right angles to but outside of a group of going and return conductors will usually heat less than an iron member crossing a single conductor, when the current and minimum spacings are the same.

3. The temperature rise of structural iron beams in large rectangular magnetic frames surrounding a straight conductor (as in isolated-phase layouts) and having sides larger than, say, 5 ft. may be calculated separately for each individual beam disregarding the other three sides of the frame, even if the conductor passes near the corner at a point as close as 8 in. from the nearest part of each of the two adjacent sides. Small closed structural steel frames or ducts having sides of the order of two ft. or less, when surrounding a conductor, must however be expected to heat considerably more than a single straight iron member passing at right angles to a conductor, for equal spacings and currents.

4. A long and narrow steel member, such as an I-beam or a channel, will ordinarily heat much less when running parallel to a conductor than when crossing it at right angles, for the same spacings and currents. This is because in the parallel arrangement the iron portion of the flux path around the conductor is usually a much smaller part of the complete flux path than in the case of a steel member crossing at right angles to the conductor. It will, therefore, often be advantageous, from the standpoint of iron heating, to lay out stations with conductors parallel rather than at right angles to the iron members.

5. For various sizes of straight long solid structural iron members crossing ar right angles to a conductor and having a thickness not less than 1/8 in., when placed with respect to the conductor at any one center spacing within the range from, say, 6 to 16 in., the temperature rise was practically independent of the size, or cross-sectional area or shape of the iron member. In the same tests the losses of the various solid structural iron members not thinner than 1/8 in. were proportional to the perimeter of the iron cross section regardless of shape or volume. The iron members in question ranged in size from a 1¼ in. standard pipe to a 12 in. by 10 in. I-beam.

6. The values of temperature rise of structural iron members at the frequencies of 25, 40 and 60 cycles per sec. were roughly in the ratio of 1:1.3:1.6; *i.e.*, the 60-cycle temperature rise was 60 per cent higher than that at 25 cycles per sec.

7. The circulating current in a 6-ft. by 6-ft. channel iron frame was of the order of 100 amperes when a straight 3000-ampere conductor was run parallel to one side of the frame and at 10 inches center spacing from the nearest channel iron, the conductor being outside the frame but in the same plane with it. The temperature rise of the iron was negligible. While the observed current in the 6-ft. by 6-ft. frame was small, considerably larger currents of, say, several hundred amperes may flow in heavy structural-iron frames of isolated-phase stations when the iron loops are large (say 15 or 20 ft. on a side) and especially when a heavy-current bus follows two sides of the frame or when the flux linking the iron loop is materially increased by the effects of other conductors.

8. Short-circuited copper loops or bands around iron members crossing at right angles to heavy-current conductors may be effectively used to reduce the losses and temperature rise of the iron; but when designed with too small a current-carrying capacity, the copper loops themselves may seriously overheat. In two typical cases a copper sleeve, or short-circuit winding, having an ampere-turn capacity of 30 per cent of the busbar current reduced the iron losses and temperature rise to less than 10 per cent of their original values.

Acknowledgment. The authors are indebted to Mr. D. Basch for the use of iron-heating data obtained under his direction in a number of the earlier tests.

NEW DISCOVERY MAY BROADEN ELECTRIC TRUCK FIELD

The recent discovery of a new element making possible much lighter storage batteries, as reported late in March from Vienna, Austria, will, when perfected for commercial use, broaden the transportation field now served by the storage battery truck. It is said that the new element is one-fifth the weight of lead and surpasses the lead accumulators now used in storage batteries in both capacity and power. That electricity is playing an important role in transportation is evidenced by the many installations of the electric truck for industrial plant hauling and city delivery service.

THE LONGITUDINAL FORCE IN CONDUCTORS

BY CARL HERING

The existence of a mechanical force in the direction of the axis of a conductor, the recognition of which the writer has been urging for many years, has been strenuously opposed by many (chiefly teachers and book writers) because it does not fit in with Maxwell's mathematical system, which recognizes only perpendicular forces. No one, however, has shown that it does not nor cannot exist, and it seems that its acceptance is now gaining, though slowly.

The following seems to convince opponents better than the writer's numerous other experimental proofs.* A loop of very flexible wire laid irregularly on a table, or floated on mercury, when insulated from it, will expand into a circle (or into a figure 8) when a strong current flows through it. The radial pressure of the flux inside of the loop is then balanced by a tensional force in the wire, quite analogously to these forces in a soap bubble or a toy balloon. This is the much disputed longitudinal or stretching force. This (as well as the radial force) is due to the mutual repulsion of the flux lines around the wire, and is an internal force or stress, due to its own flux; it should be carefully distinguished from the forces due to the flux from external circuits. Neither Maxwell nor Ampere seem to have known of the existence of any internal forces.

In the single, straight, conductor (one which is far removed from all others) the writer computed this force to be $i^2/200$ dynes, in which i is in amperes; hence it is very small. If certain newer theories are correct, it would follow that with 100 amperes in a single-turn circular circuit of 40 cm. diameter and 6 mm. diameter of wire, this force ought to be roughly about one gram, hence considerably greater, and the product of this force by the circumference of the circle, ought to be equal to the stored energy. This is a deduction and remains to be checked by tests, as this force has, apparently, never been measured before.

To enable passengers to see scenery at night, the Chicago Milwaukee and St. Paul Railway will, it is understood equip all observation cars on transcontinental trains with powerful adjustable floodlights.

Some 45 patents are said to be pending on a new process of taking and showing stereoscopic ("3-dimensional") moving pictures. A minimum screen width of 38 feet is required.

A blue glass recently concocted at the United States Bureau of Standards has the property of furnishing protection against ultra-violet rays. About half the lime in a soft soda-lime glass is replaced with cerium oxide, and sufficient cobalt oxide added to produce the desired color.

Tests of Paper-Insulated High-Tension Cable

BY F. M. FARMER[1]
Fellow, A. I. E. E.

***Synopsis.**—The paper deals with those tests which are involved in specifications. The discussion is from the standpoint of the purpose and significance of the various standard tests which are made rather than that of the technic of the details of testing. A considerable number of data are given.*

The subjects treated are purpose and importance of tests of cable; insulation resistance test; high voltage test; dielectric loss and power factor test; "ionization" test; bending test; accelerated life test; preparation of samples for high-voltage tests and tests of components.

The possible significance of wide variation in some of the properties of cable is discussed. The relation found between time and voltage based on a large number of tests of both three conductor and single conductor cable is discussed at considerable length. A test for stability of the impregnating compound is described as is also a proposed standard load for dielectric-loss testing. Some data are given showing the effect of repeated bending on lead and how that effect is influenced by the tensile stress in the lead.

The paper concludes with a list of the ways by which, in the author's opinion, progress can be made in the improvement of the quality and the design of paper-insulated high-tension cable.

* * * * *

Introduction

Tests which are made on paper-insulated, high-tension cable may be divided into the three following general classes:

a. Research tests for the ultimate purpose of advancing this branch of the electrical industry by means of improvements in quality of materials and manufacturing processes, or improvements in cable design.

b. Tests on the commercial product at the factory to determine compliance with the manufacturer's standards or the purchaser's specifications.

c. Tests on cable after it is installed, including acceptance tests on new cable, periodic tests and fault location tests.

It is not feasible to cover even superficially all of these tests within the limits of one paper. It is, therefore, proposed principally to discuss those standard tests which are involved with specifications and certain other tests which, while not yet in specifications, aid in determining the quality of cable and the improvements which have been made therein. Furthermore, it is not proposed to discuss to any great extent the details of the technique of testing cable, but rather the purpose and significance of tests.

Purpose and Importance of Tests of Cable

Ostensibly tests in connection with the purchase and acceptance of cable are made for the purpose of determining whether or not the material complies with the specified requirements. The basic object, however, is to determine the suitability of the cable for the service to which it is to be applied. The specifications are, in effect, simply the engineer's method of describing cable which it is believed will be suitable for that service.

In no class of electrical apparatus does more reliance have to be placed on tests to determine suitability than in the case of cables. Insulation is a more or less important feature in all electrical apparatus but in high-tension cables it is *the* factor. The insulation in a high-tension transformer for example is, of course, of prime importance but the amount involved in the largest unit is insignificant compared to that in a cable line of average length. Consider for instance, the 66-kv. line of the Cleveland Electric Illuminating Company which consists of two three-phase circuits of three, single-conductor cables each. This line is about eight miles long and contains, therefore, about 50 miles of cable. The mean area of the insulation of this cable is about 123,000-sq. ft. or a little over 2.8 acres. While a few hundred sq. ft. of insulation are continuously under stress in the transformers at each end of this line there are nearly three acres of insulation buried in the ground, every square inch of which is expected to withstand continuously all day and every day a potential of 38 kilovolts.

Unfortunately we know far less about insulation than about any of the other essential classes of materials in electrical apparatus. In the case of cables, we impose particularly severe conditions because we effectually cover the insulation with a sheathing of lead so that no visual inspection whatever is possible and the sins of omission and commission, are thoroughly buried. We must, therefore, determine the suitability of this important part of a cable very largely by tests. Perhaps a better way of putting it would be to say that the best we can do is to make certain tests with the hope that, in the light of our present knowledge, they will eliminate cable which would be unsuitable for the intended service as prescribed by the specifications.

Insulation Resistance Test

The test for insulation resistance is one of the earliest made on electrical conductors. In the early days of the art when only low voltages were involved it served very satisfactorily as a means of detecting sections of wire or cable which would be likely to prove unsatisfactory in service. At such low voltages the inherent quality of the insulation did not have to be of a very high order and the principal things to be guarded against were mechanical defects and accidental injuries. The insulation

---

1. Chief Engineer, Electrical Testing Laboratories, New York, N. Y.

Abridgment of paper to be presented at the Regional Meeting of the A. I. E. E., District No. 5, Madison, Wis., May 6-7, 1926. Complete copies available upon request.

resistance test served very well in weeding out wire or cable defective from these causes.

With the advent of higher voltages it was found that insulation resistance tests were of very limited usefulness in determining the inherent value of the insulation and that other tests were much more important in insuring a satisfactory product. It is now generally recognized that the number of megohm miles of a cable has little significance and no one can predict that a cable with high-insulation resistance will give better service than one with low resistance or vice versa.

While the actual value of the insulation resistance in megohm miles may not be significant, the *variation* in

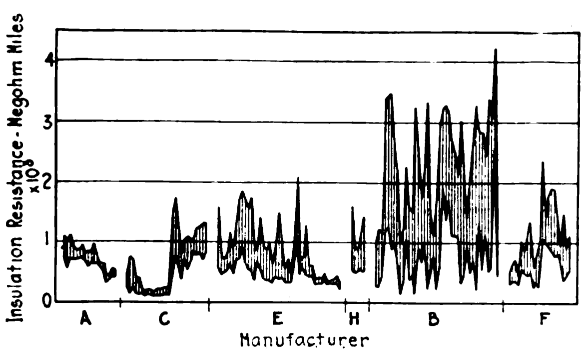

FIG. 1—INSULATION RESISTANCE OF 13-15-KV. CABLE INSPECTED DURING 1925

Upper line, maximum insulation resistance in each lot inspected
Lower line, corresponding minimum insulation resistance

the megohm miles between different sections of the same cable line, which are supposed to be identical in quality, may be very significant. The variation in the quality of high-tension cable is one of the greatest problems in the cable art for it is the weakest link in the chain that determines its strength and the problem of producing cable which is uniform from section to section or even foot to foot has yet to be solved. Obviously, cable having the least variation in quality is better than one the quality of which, although it may have a higher average value, varies over a wider range.

Fig. 1 has been prepared from insulation resistance measurements made in the course of the routine inspection of high-tension cable at six factories during 1925. The upper heavy line connects the values of maximum resistance found in each lot of cable and the lower heavy line connects minimum resistances. Each light vertical line connects the maximum and minimum values of resistance found in each lot submitted. The shorter the light vertical line is, the smaller is the variation in a single lot. The smoother the heavy lines are, the smaller is the variation between lots. It is evident that make "B" takes first place for variation while make "A" is conspicuously uniform, with "C" a close second.

Just what the practical significance of these differences in uniformity of insulation resistance is, we do not know. With respect to quality of the cable, these differences may mean much or they may mean little but it is submitted that until we have some means of measuring the quality of insulation more directly, we are justified in concluding that other things being equal, the cable with the smaller variation is the better.

HIGH-VOLTAGE TESTS

High-voltage tests of various kinds have long been considered the most important of all that are made on high-tension cable. They may be classified into (a) fixed or stated voltage tests, (b) momentary breakdown voltage tests and (c) time breakdown voltage tests.

(*a*) *Fixed Voltage Tests.* A fixed voltage test consists in the application of a prescribed voltage for a prescribed length of time to each reel of cable in the case of acceptance tests at the factory, or to an entire line of cable in the case of installed cable.

Volumes on the discussion of this subject of fixed voltage tests of insulation for all purposes, and cable in particular, have been printed. How high should the test voltage be and how long should it be applied to insure that the cable meets the desired standard without injuring the insulation? Which is the more effective, high voltage for a short time or a lower voltage for a longer time? These are questions which are still answered by opinions to a large extent. We do not as yet have all the facts definitely established which are essential to the formulation of the true answer.

What is the purpose of this particular voltage test? We encounter two serious obstacles when arriving at the suitability of a piece of cable. In the first place, the insulation is buried out of sight and in the second place, it is far from homogeneous. A member in a steel structure can be put in place with almost complete

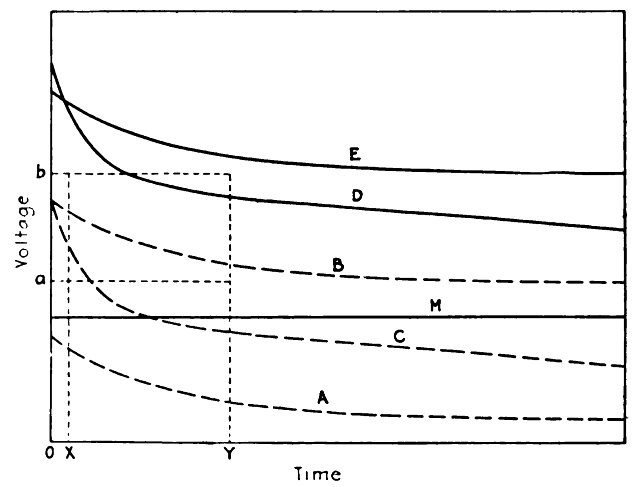

FIG. 3

confidence that it has 100 per cent reliability if it passes a visual inspection. But in the case of a length of cable we cannot judge by inspection whether it will serve the purpose intended nor can we depend absolutely upon a test to destruction of a specimen because of the lack of uniformity. We must "load" every foot of cable, that is, subject it to a voltage well above the

rated voltage—if we are to be assured of a reasonable "factor of safety."

The test should preferably accomplish two things,—eliminate cable the insulation of which is electrically weak because of accidental defects, and eliminate cable which is electrically weak because of the inherent low quality of insulation.

One way of visualizing the conditions with which we have to contend is indicated in Fig. 3. It is well established that the voltage which a given piece of insulation will withstand is greatly effected by the test conditions, one of the most important being the time of application of the voltage. Each portion of insulation has its own voltage-time characteristic which can be indicated in the general manner shown by the curves in the diagram.

Now, consider a section of cable with an accidental defect of a mechanical nature such as external damage to the insulation, registration of a large number of tapes, cracked or torn insulation, etc. The breakdown voltage of the section of cable will, of course, be that of the insulation at this point, and if the injury is serious, the breakdown voltage will be much below that of the rest of the section. Nevertheless, that spot has a time-voltage characteristic which we can indicate by curve A. But a moderate test voltage, a, even if applied only momentarily will cause puncture and therefore eliminate that section. If the defect is less extensive so that a lesser thickness of the insulation is effected, the curve may be something like B in which case, a test at a volts even if applied for y time, will not eliminate it. Nevertheless, its so-called permanent breakdown voltage, *i. e.*, the maximum voltage which it will withstand indefinitely is not sufficiently above the operating voltage, M, to provide the necessary factor of assurance. On the other hand, a test at b volts, even if only momentarily applied, would eliminate it.

Next, assume a spot which is inherently electrically weak due, for example, to incomplete saturation or overheating at a lead press mark. The insulation at that point may have a high momentary dielectric strength without a correspondingly high endurance strength due to high dielectric loss which causes failure in accordance with the thermal theory of Steinmetz and Wagner. The characteristic curve at this point might be of the shape indicated by curve C, in which case a test at a volts for a time x would not eliminate the section but a volts for y time would.

Normal cable may have a characteristic like curve E or curve D. The former is obviously the preferable type of curve. Both curves are higher than those for the other cases, consequently the test voltage should be adjusted to the normal cable and not to the abnormal cable only. The problem is then to determine the voltage which should be applied to insure as high a curve E as possible, and for as long a time as practicable in order to eliminate cable with too much of the characteristic indicated by D. This would be accomplished by applying b bolts for y time.

The practical question is then, what should the voltage be and for how long should it be applied? This question has been with us since the beginning of the industry and is likely to remain with us for some time to come. It is to be noted, however, that the trend in fixed voltage tests is very definitely upward both as to voltage and time. For instance, the A. I. E. E. rules adopted in 1911 prescribe double normal rated voltage for one minute. The standards of 1922 prescribe two and one-half times operating voltage for five minutes while those adopted August 6, 1925 prescribe three times the rated voltage plus 2 kv. for five minutes. The most recent specifications in wide use, namely, those of the Association of Edison Illuminating Companies, prescribe test voltages substantially in accord with the latest rules of the A. I. E. E. but the test period is fifteen minutes instead of five minutes. So, despite our lack of facts and figures, general knowledge and experience has gradually pushed up the test voltage and lengthened the time of application.

(*b*) *Short-time Breakdown Voltage Test.* The fixed voltage test will not of course tell us what factor of assurance we are getting. We try to get some light on that question by means of short-time breakdown voltage tests, *i. e.*, by testing short samples to destruction. The light we get, however, is rather feeble for after we have obtained the so-called momentary puncture voltage, we cannot coordinate it with the rated or operating voltage of the cable. This is due not only to the dielectric strength-time relation referred to in the preceding discussion, but to the variation in the material. The latter point could be taken care of by testing enough samples but any such procedure sufficiently extensive to truly represent the product would be quite impracticable. However, short-time tests do give us data which indicate the trend at least of the dielectric strength.

Table I shows a summary of a large number of tests made in 1923, 1924 and 1925 respectively on cable manufactured under the N. E. L. A. specifications. The results are reported in average volts per mil. Cables of all sizes and voltages are included, so that some common basis must be used.

TABLE I
DIELECTRIC STRENGTH OF CABLE

Year	No. of Tests	Average volts per mil at breakdown			Per Cent inc. in Average over 1923
		C-C	*C-S*	Average	
1923	260	291	283	287	..
1924	290	307	284	306	6.6
1925	106	354	357	355	23.7

"*C-C*" — between conductors.
"*C-S*" — between conductors and sheath.

It is evident that the dielectric strength of cables has been steadily increasing—being nearly 25 per cent greater on the average in 1925 than it was in 1923.

(c) *Long-Time Breakdown Tests.* The preceding discussion has indicated that one of the most important things which we would like to know is the *maximum* voltage which each length of cable will withstand indefinitely. The only way to get this information is by a series of tests to destruction by subjecting several samples of the same cable to different voltages continuously until failure occurs. Sufficient tests of this kind will give data from which a reasonable reliable answer to the above question can be made. Such tests are, however, very expensive as much time is required and also a considerable amount of costly cable. However, the significance and importance of such information is being recognized and it is felt that we have reached a step in the development of the art where this knowledge is essential to further intelligent progress. The cost of acquiring the necessary data is secondary in view of the importance of cables in the electrical industry and the large amounts of money being invested in them.

A considerable amount of this kind of testing is being done—some by the manufacturers and some by the utility companies, particularly the Commonwealth Edison Company of Chicago. Electrical Testing Laboratories are also doing a considerable amount of this class of cable testing and some of the data shown in the accompanying diagrams are made available through the courtesy of its clients, particularly the High-Tension Cable Committee of the Association of Edison Illuminating Companies.

The results of about 30 tests of three-conductor cable of various sizes and voltages are shown in Fig. 6 where the maximum stress gradient at the conductor

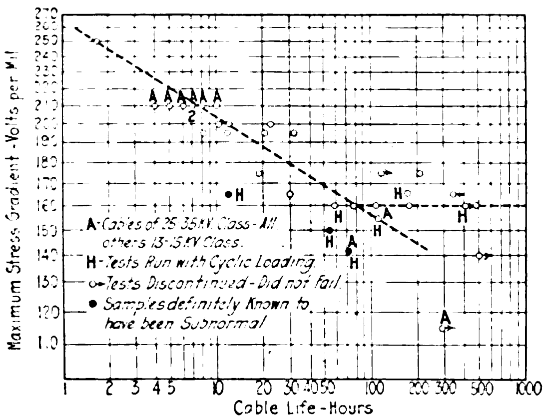

FIG. 6—CABLE TESTS (TIME-STRESS DIAGRAM) THREE-PHASE TESTS, THREE-CONDUCTOR CABLE

surface is plotted on logarithmic coordinates against time.

It will be noted that while the data are quite insufficient to justify anything like a final conclusion, they do suggest a more or less critical point in the life curve beyond which the cable will have indefinite life. That is, the broken line which is a reasonable mean of all of the points, suggests that, at a stress lower than about 150 or 160 volts per mil maximum stress gradient, the life will be indefinite (or at least will decrease at a very low rate) and that at higher stresses the life will vary inversely something like the seventh power of the maximum stress gradient. However, much more data are needed before this indication can be definitely established or disproved.

Fig. 7 shows some similar data, plotted in the same manner, which were obtained on 44 samples of single-conductor cable for very high voltages. If the points enclosed by the dotted line and which were obtained on specimens of two samples of cable that showed con-

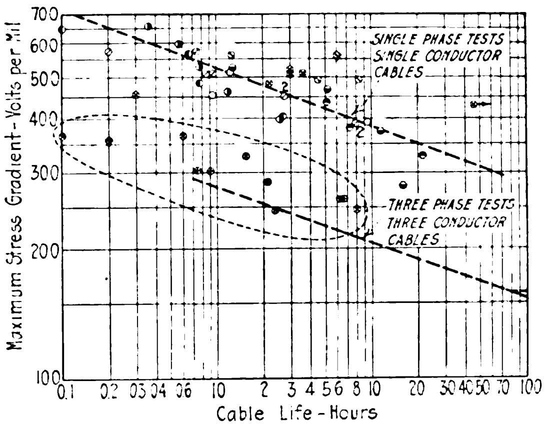

FIG. 7—CABLE LIFE TESTS (TIME-STRESS DIAGRAM)

Note: Points show single-conductor tests only. For three-phase test points see Fig. 12. Designations identify makes of cable tested

sistently much lower dielectric strength than the other samples that are omitted, a fairly definite straight line can be drawn, as indicated by the broken line.

Whether or not a critical point exists here also is not determinable because we have not as yet enough data, specially long-time data. However, it will be observed that the slope of the curve as plotted is the same as that for the three-conductor cable in Fig. 6. The left-hand portion of the latter curve extended backwards is shown in Fig. 7. In other words, the seventh power relation between the maximum stress gradients is again suggested.

DIELECTRIC LOSS AND POWER-FACTOR TEST

The practical significance of the dielectric losses in the insulation of cable was not fully appreciated until six or seven years ago when an epidemic of service failures led to the recognition of the dielectric loss type of failure. Bang and Louis[4] and other contributors to the TRANSACTIONS of the Institute have discussed the influence of dielectric loss on the carrying capacity of cables. Roper[5] has given concrete evidences of cable failures due to excessive dielectric loss. However, these losses have been so much reduced that they are no longer a serious element in cable operation. In the

5. *Dielectric Losses and Stresses in Relation to Cable Failures.* D. W. Roper, TRANS. A. I. E. E., Vol. 41, 1922, p. 547.

past four years, the average loss in 30-kv. cable dropped from about 1.6 to 0.6 watt per foot and for 13-kv. cable from about 0.9 to 0.2 watt per foot.

Power-factor measurements also provide another means of studying the problem of uniformity of cable to which reference has been made.

Lower line—Power factor at rated voltage at 20 deg. cent.

20 deg. cent. It is evident the cable of manufacturer *A* was much more uniform in this respect at least than that of the others, particularly *C* and *F*. However, Make *E*, while not quite so uniform, was consistently much lower, with a minimum change between 80 deg. and 20 deg.

Several methods of making these measurements are in use and the suggestion has been made that one method should be adopted as a standard in order to eliminate some of the differences between different laboratories, but it is not believed that this is necessary or even desirable. What we need is not a standardization of one or more methods of making the measurement itself but a convenient *standard* load comparable in magnitude to the dielectric of a piece of cable.

Such a standard which gives promise of serving the purpose very well consists of three Leyden jars made of special glass, metal coated inside by silvering plus copper plating and outside with lead by the spraying process. The tubes are about two in. outside diameter, about 16 in. long and the glass is about $^{3}/_{32}$ in. thick. They are filled with oil and will withstand the application of 25 kv. continuously. With three-phase power factor at 25 deg. cent. of the particular set in the illustration is 0.22 per cent at 10 kv., 0.27 per cent at 25 kv. and 0.32 per cent at 50 kv. At 35 deg. cent., the corresponding power factor values are 0.24, 0.30 and 0.36 per cent.

"Ionization" Test

The work of many investigators in the field of insulation research has demonstrated that the less gas there is in the insulation the better it is as an insulator.

The so-called "ionization" test, a comparatively new one in the cable art, is intended to be a test of thoroughness of impregnation. We know that in a solid dielectric free from gas the loss will vary substantially as the square of the voltage and the power factor will be constant until the voltage approaches the rupturing value—barring, of course, temperature effects due to long application of the voltage. The theory of the "ionization" test is that, if air or gas is present, it will become ionized at a relatively low stress and the power factor will depart from a constant value as the voltage is increased, at a lower value than it would otherwise.

The "ionization" test, which is the present standard for specification purposes, is the determination of the change in power factor between an average stress of twenty volts per mil and one hundred volts per mil, respectively. The specifications issued by Association of Edison Illuminating Companies in November, 1924, prescribe that this change shall not exceed two per cent for a three-conductor cable or one per cent for a single-conductor cable.

The important question in connection with this test is, what is its real value? Will cable having a power-factor difference of two per cent for example, be better than one with a difference of four per cent and if so, in what respect and how much better will it be? Dr. Whitehead has shown[7] that insulating materials which were known to be poorly saturated had a high "ioni-

7. *Gaseous Ionization in Built-Up Insulation*, J. B. Whitehead, Trans. A. I. E. E., Vol. 42, 1923, p. 921, and Vol. 43, 1924, p. 116.

zation" test result and deteriorated rapidly under the application of voltage. However, we have no definite facts in the way of test data to show how much real gain is obtained in cables when this power-factor difference is two per cent instead of four per cent or one per cent instead of two per cent. Before reducing the permissible variation we should have definite knowledge on this point if such reduction involves increased manufacturing costs.

Bending Test

One of the most important tests in American cable practise is the bending test. It was introduced into cable specifications only five or six years ago but it has undoubtedly been an important factor in the marked improvement in workmanship and in the fabrication of the insulation of cables which has taken place. Excessive tearing was at first a common result in a bending test but now it is a rare occurrence. Furthermore, the insulation is tighter, more evenly applied and is practically free from wrinkles. Even in the case of cable with wood-pulp paper insulation, while there has been some improvement in the mechanical strength properties of wood-pulp paper, the improvements in fabrication processes have enabled such cable to pass this test—something that could not have been done two years ago.

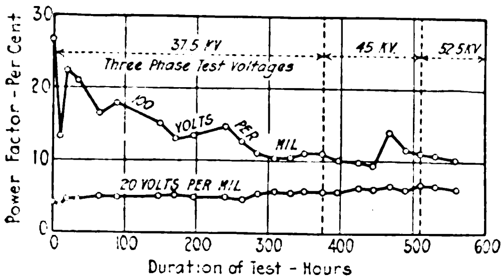

Fig. 16—Power Factor Variation with Time, Between Conductors

Insulation: paper, 14 x 10/32 in. *B C* and *B C L*
Conductors: 3-350,000-cir. mil sector

Table III shows in a striking manner the improvement that has been made in the ability of Manila paper-insulated cable to withstand this bending test, as measured by puncture tests. The figures given are grand averages of tests made on samples of cable of various sizes and voltages.

The last column shows what marked improvement has been made in the past three years—the effect of bending having dropped from 21 per cent to practically zero. In other words, present-day cable will withstand this severe bending test without any appreciable effect on the dielectric strength.

Tests of Components

Most cable specifications include some requirements, either general or specific, which necessitate certain tests to be made on most of the component parts of the cable. In addition, others not specifically required, are frequently made for the purpose of obtaining information.

Paper tests of paper removed from samples of cable are tested for composition of stock, tensile strength, tearing strength, folding endurance, dielectric strength and sometimes porosity or air resistance. Occasionally, also the dielectric constant is determined. Methods which are more or less standardized are usually employed for these tests but they will not be discussed here. It may be of interest, however, to note the general average value of some of the properties during the past three years, as shown in Table IV.

Tests of Compound. Few of the usual tests which are normally made on insulating materials can be applied to the compound in cables by the purchaser because the only way he can obtain sufficient quantities of a compound from the sample of cable is by extraction with benzol or other solvents.

A test that is frequently made is the determination of the approximate proportions of saponifiable and unsaponifiable constituents which are usually vegetable base and mineral base materials, respectively. It has been previously indicated that mineral base compounds have in general a much lower dielectric loss than vegetable base compounds but the latter has desirable viscosity and dielectric strength characteristics. A knowledge of the general composition of a compound is therefore useful as a check on the test results obtained on the cable itself.

been responsible for failures of the former type of cable. A few months service experience with the first high-voltage cables impregnated with mineral base compounds showed that an unknown, solid material, cellular in structure and extremely light, formed in the interstices of the insulation and failures too frequently followed in the course of time. It was evident, as is so often the case, that the elimination of one defect was being accompanied by the introduction of another.

In order to form this unknown material in any practical length of time, the compound must be subjected to stresses which are above the breakdown value. This is best done by placing the compound between concentric glass cylinders or between parallel glass plates. In the latter method as used at the Electrical Testing Laboratories, a film of the compound about three mils thick is placed between two lantern slide glasses on either side of which is a flat electrode to which the potential is applied. The upper electrode is removed at intervals and any change in the character of the film is noted.

Fig. 26 is a photograph of a test specimen before and after subjection to this test. Fig. 27 is a curve obtained with petrolatum which shows the time at which this unknown material, *X*, forms at various stresses—the stress being calculated from the measured dielectric constant of the glasses and the compound, the thickness

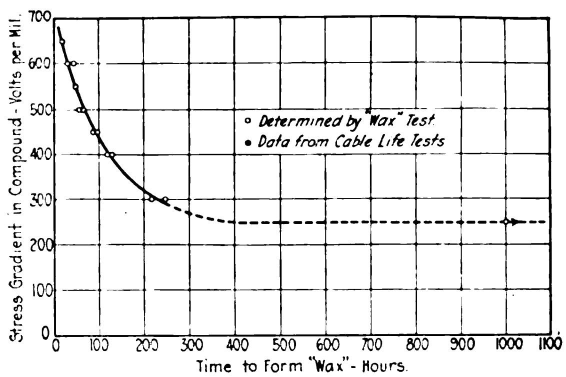

FIG. 27—WAX TESTS—TIME-STRESS DIAGRAM

of the glasses and the film, and the applied voltage. It seems reasonably safe to assume from the trend of the curve that in a sufficiently long time more or less *X* could be expected to form even at stresses existing in high tension cables in normal operation, that is, of the order of fifty to seventy-five volts per mil.

While the absence of any signs of disintegration in a compound when subjected to this test is not a guarantee that it will remain unchanged indefinitely in a cable,

TABLE V

Load lb.	Stress lb. per sq. in.	No. cycles of bending	Remarks
0	0	8710	First cracks noted

Note: First group of specimens from one piece of lead, other two from another piece.

it seems reasonable to assume that if 600 volts per mil for seventy-two hours at either room temperature or at 75 deg. cent. does not produce any change, the chances of disintegration taking place in service are rather remote.

Conclusions

The problem confronting the engineer responsible for an underground cable installation is the transmission of the most energy per dollar of annual cost, *i. e.*, per dollar of investment and per dollar expended in maintenance. The investment cost will depend not only upon the voltage employed, which presumably will have been selected after proper consideration of the economics of the situation and the local conditions, but also to some extent on the quality of the cable, for, the better the insulation, the less of it has to be used and the lower will be the cost. The maintenance cost, however, is largely a matter of quality although the cost of repairs due to inferior workmanship on splices, careless handling of cable during installation and other avoidable causes is not an insignificant item.

Every failure in a cable costs money in direct outlay for replacement of cable and for withdrawing the old cable and installing the new, in addition to splicing and other incidental expenses. There is the further effect of cable failures that cannot be evaluated, namely, the disturbance to the service, the continuity and dependability of which is such an important element in the "good-will" of an electric public utility.

The record of cable failures quoted above might be considered good and perhaps it is in comparison with the records of other electrical apparatus, particularly when the comparison is on the basis of the area of insulation involved. But it is the function of the engineer to make the record better and thereby reduce the maintenance cost in which cable failures form so large a part.

It is obvious that the greatest reduction in the number of cable failures is to be effected through improvement of the quality and through improvements in the design. Progress in both of these directions can be made in the following ways, all of which involve comprehensive and systematic testing of the kinds discussed in this paper:

(*1*) *Research by both manufacturers and users.* It is the manufacturers' problem to improve the quality of the materials which make up a cable. It is also their problem to improve manufacturing processes in order to produce cable which is not only better cable but which is more uniform. It is the users' problem to carry on investigations which will provide information that will permit more efficient operation based on facts rather than opinions and which will indicate the direction in which improvements are needed to meet the present and future requirements of the industry.

(*2*) *Thorough and systematic inspection and tests of cable when purchased.* While the immediate, primary purpose is to insure compliance with the contract, the greatest value of inspection and tests is likely to be the fact that it provides the means of obtaining definite, quantitative knowledge of the quality of cable. Such knowledge must be available before a reference point can be established and progress accurately measured.

(*3*) *Evaluation of cable.* The development of a satisfactory method of quantitatively evaluating cable through suitable weighing and combining the results of inspections and tests would provide a very useful incentive to progress.

(*4*) *Specifications.* Cable specifications must, of course, be based on current practise and consequently revisions of existing requirements must follow progress in the art. However, keeping specifications up to date so that they include advances as they are made does, in itself, contribute to the general progress through setting a high standard for *all* manufacturers and for *all* users rather than the *few*.

(*5*) *Periodic examination of cable in service.* Improvement in cables would unquestionably be greatly aided if we had more knowledge of what takes place in a cable which causes it to deteriorate and ultimately fail. Apparently all of the equipment on the system is given a more or less systematic inspection except the cable which is buried in the ground and forgotten until trouble develops. Samples should be removed when a convenient opportunity is afforded and examined and studied so that we can learn, if possible, what it is that determines the life of the cable and thus aid progress by indicating the direction of improvement both in the cable and in the specifications for the cable.

NEW TRAFFIC SIGNALS FOR CHICAGO

On February 7th, new traffic signal equipment went into service in the *Loop* district in Chicago at forty-nine street intersections. All this apparatus, equipped with three-light traffic signals at each corner, is served from underground circuits terminating at the City Hall where a central control board is located. This board provides an extremely flexible control, it being possible to vary the intervals between traffic halts at intersections along the same street. The ratio between periods on intersecting streets may likewise be varied. The control board was built under the specifications of the Department of Gas and Electricity.

New traffic-control equipment is also being installed outside the *Loop* district on eighty-seven intersections, some involving three streets. These signals are controlled by local panels which also permit flexible combinations of operation. Energy for the units outside the loop will be furnished by the Commonwealth Edison Company. Signals within the loop will be operated between 7:30 a. m. and 12:30 midnight.

Some Interconnected-System Operating Problems

BY FRANK G. BOYCE[1]

Member, A. I. E. E.

Synopsis—*This paper outlines the advantages and disadvantages of an interconnected system consisting of steam and hydroelectric stations. Investment costs are materially reduced because of less reserve capacity being required to insure continuous service. More efficient operation of generating units is possible and operating costs are reduced. Electrical disturbances are magnified and large generating stations must be located near the heaviest load centers so that the system may be split up to localize disturbances. A well-trained corps of load despatchers must be available and they must be fully informed of all conditions on the system which may affect operation.*

* * * * *

MUCH has been said and written of late regarding interconnected systems. In fact, "superpower" and "giant power" are almost as popular today as radio. Magazines and the daily news contain much information and misinformation on the subject.

The purpose of this paper is to bring out some of the economic and operating problems which must be kept in mind in the design and operation of an interconnected system of steam and hydroelectric generating plants and to show how these problems have been solved in some instances.

It must be kept in mind that while people in the metropolitan centers are accustomed to a very high quality of service, yet in the smaller towns and suburban sections the use of household appliances, electric refrigeration, electric cooking, water pumping and miscellaneous small motor uses are now quite common and are increasing at an amazing rate. These uses are demanding that the small towns and villages receive the same grade of service that the large cities have enjoyed and at the same time the investment must be kept sufficiently low so that this service can be furnished at a rate which will encourage the use of electrical energy and will compete with isolated plants.

The investment in generating equipment per kw. of installed capacity can usually be kept lower by interconnection, for it is possible to adequately safeguard service with a lower investment in reserve equipment, as reserve in any section of the network is available to supply demands in other sections and practise seems to indicate that sufficient reserve to replace the loss of the largest single generating unit is adequate.

Usually maintenance work can be so scheduled that it can be carried on in the hydroelectric plants during the period of minimum stream flow; likewise, work of this nature can be carried on in steam-generating plants during the period of maximum flow. This work can also be so arranged that only a predetermined amount of capacity on the entire system will be out of service at one time. By following the schedules given above, the greatest amount of the combined capacity of the entire system is kept available at all times which assists in keeping the amount of reserve capacity to a minimum.

1. Consumers Power Company, Jackson, Mich.

To be presented at the Regional Meeting of District No. 5 of the A. I. E. E., Madison, Wis., May 6-7, 1926.

Interconnection has made possible the greater use of automatic generating equipment, especially in the smaller hydroelectric plants. Very often the cost of maintaining operators at small hydro plants makes the cost per kw-hr. delivered from these plants so great that these plants become a liability. As systems grow in capacity, the smaller plant becomes less important with reference to the system demand, its principal value being the kw-hr. it can deliver to the system. In such a case, if the plants can be made sufficiently automatic to operate so as to obtain the most efficient use of the available water, their operation can be made profitable and others developed, provided the investment can be kept sufficiently low. It is thought that there is room for development along the lines of cheaper and simpler methods for accomplishing this. In some cases the small plant may be made semi-automatic, requiring only a simple means of opening the oil circuit breaker and shutting down the waterwheel. A number of such installations, some of them rather crude, have been in successful service for years.

Consideration should be given to the location of generating units at strategic points in the network with reference to the load centers. In some cases, generating units can be so located that a transfer of any large amount of power over a great distance will be unnecessary. In considering the location of generating units, some thought should be given to the sectionalizing of the system at times of serious trouble in one portion of the network. If this is done, the trouble will be confined to the smallest possible area. It is sometimes desirable to sectionalize the system when severe lightning storms occur over a portion of the network so that surges caused by lightning strokes will not be transmitted to other parts of the system.

The combination of steam and hydroelectric plants in one system allows the most effective use of the kw-hr. capacity of the hydroelectric plants and at the same time allows the operation of steam generating plants at their most efficient loads.

A greater number of hydroelectric units can be operated during heavy load periods, permitting the elevation of the storage reservoirs to be lowered slightly. During low-load periods a greater percentage of the system load can be carried by the steam generating units, allowing the hydroelectric reservoirs to return

to their normal elevation so that the hydroelectric generating plants are ready to repeat this cycle of operation at the return of the heavy load.

When a large number of plants are feeding into one network, all hydroelectric units can be operated at the most efficient gate openings at all times, thus obtaining the maximum kw-hr. output from the available water; likewise steam generating units can be operated at their most efficient loads. Changes in the system load can be taken care of by starting up or shutting down units.

Tests can be made which will determine the most efficient load at which boiler units will operate and as the system load requires, additional boilers can be fired or banked, or additional steam turbine units can be brought into service.

The efficiencies of steam generating plants are greatly increased by operation in conjunction with hydroelectric plants, because although the hydrostorage reservoirs may be small, yet the great flexibility of hydroelectric plants, due to storage reservoir capacities, permits the changing of loads on steam generating plants in blocks according to the most efficient load which can be carried on boiler and turbine units then in operation. The extent to which this can be carried out will be realized when it is pointed out that on a system having 10 steam generating plants ranging in capacity from 400 kw. to 40,000 kw. (some of these plants being rather old ones) a system of fuel economy for one year of approximately 21,000 B. t. u. was obtained, while if these plants were operated as isolated ones, the B. t. u. per kw-hr. would have been considerably higher.

It is also possible to obtain a greater kw-hr. output from hydroelectric plants operating as a part of one of these systems. As an example, one hydroelectric plant which has been operating for a number of years as part of an isolated system at a yearly output of 2,006,600 kw-hr. was recently made a part of a combined system and the output was increased to 2,797,900 kw-hr. per year.

It has been found that the efficiency of both hydroelectric generating plants and steam generating plants can be improved by dampening the governing mechanisms so that all of the plants will operate as base-load plants except with such capacity as is necessary to maintain system regulation. The governors on the hydroelectric units will be so set that they will be operating at the most efficient gate opening and at the same time governors on the steam generating units will be so arranged that they will be operating at their most efficient loads. This is made more certain on the steam generating units by the installation of what might be called a "load limiting device," which is attached to a General Electric turbine, as shown in Fig. 1. This device prevents the governor valve from opening beyond a certain amount, preventing the unit from carrying more than a predetermined amount of the system load. This does not in any way endanger the operation of the unit, for if the unit would be suddenly relieved of its load or should speed up for any other reason, the governor will function normally. This device can be so set that any predetermined amount of load will be carried by the unit, which amount can be changed very quickly by the operator. The hydroelectric units can be equipped with "load limiting devices" very similar to the above in order that these units can be set to operate at their most efficient gate openings.

The mechanical and electrical design of these plants can be much more simple than isolated plants. The electric equipment will usually consist of one bank of step-up transformers with its high-tension and low-tension circuit breakers. It will also contain one set of low-tension busbars with an oil circuit breaker for each generator and one bank of transformers to supply power for station auxiliaries.

In some cases it is feasible to omit the low-tension busbars and oil circuit breakers, installing a transformer bank for each generator with oil circuit breakers on the high-tension side of the transformers. These plants

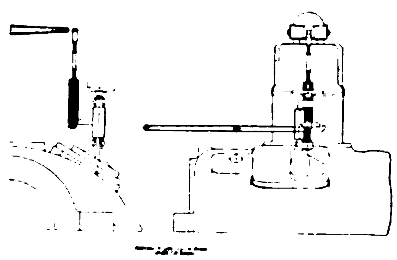

Fig. 1—Assembling of Load-Limiting Device Installed on 20,000-Kw. Turbine

require very modest expenditures for buildings as in most cases the transformers and in some cases the busbars and oil circuit breakers are installed outdoors.

The mechanical design is simplified by the elimination of many of the otherwise necessary duplicate station auxiliaries. The auxiliaries can in most cases be electric driven, obtaining their supply of power from the main busbars. If in an extreme case these auxiliaries should fail, a momentary interruption to the plant would probably result but would perhaps be unimportant, as the system load would be carried by reserve in the other plants until the plant which is in trouble is returned to service.

One item of very great importance in the mechanical design of hydroelectric plants is the facilities for spilling water, should the plant be suddenly relieved of its entire load. This is especially important in low-head plants where the storage capacity of the reservoirs is limited. Plants designed for interconnection are often connected to transmission systems by one bank of transformers or a single transmission line and do not supply a local power load, in which case an interruption to either of these removes all load from the plant. Arrangements must be made immediately to take care of stream flow.

One of the early methods used consists of a Tainter gate arranged to be raised by an electrically driven winch, operated by means of a crank in case of total interruption to power supply. This device was fairly satisfactory although in this climate it was found necessary to keep the gate free of ice, an operation requiring considerable manual labor. This type of gate was later improved upon by totally enclosing and installing steam coils inside the housing; thus, the gate could be held at a temperature that would keep it free from ice. This requires considerable fuel to maintain proper temperature.

There are a number of other methods in use, including the different types of conduit spillways in which the amount of water spilled is controlled by means of gate valves, butterfly valves or Broome gates. These methods are successful and have some advantages over the Tainter gates, aside from overcoming the ice problem.

As the length of transmission lines involved in a network and the connected capacity increases, the frequency and severity of disturbances is apt to increase. This should be kept in mind particularly when large metropolitan centers are concerned with large blocks of power concentrated in small areas. Insulation which is adequate for a system consisting of short low capacity lines will be entirely inadequate as the system grows. Thus, it is often found necessary to completely rebuild transmission lines and substations and install oil circuit breakers of greater rupturing capacity, replacing apparatus which was adequate in itself, before these units can be made a part of a larger transmission system.

A study of the proposed location of transmission lines with reference to the paths generally taken by storms is desirable in order that such lines can be so located that they will least be affected by these disturbances. Where more than one line is to be built between two points, it is often desirable to locate these lines on entirely separate rights-of-way so that all transmission lines will not be subjected to atmospheric disturbances at the same time.

In designing transmission lines, it must be remembered that materials used in their construction, such as steel, cement, porcelain, copper and aluminum, are exposed to the air, subject to all of the ravages of the elements—extremes of heat and cold, vibrations and strains caused by wind and heavy loading by sleet. It has been found that, especially in the northern climates, action of the weather has a deteriorating effect on the ordinary mixtures of clay and cement. The subjecting of these materials, with their different coefficients of expansion to the varying conditions of moisture and temperature, has caused unthought of failures requiring research and continuing improvement in design.

Periodic inspections of transmission lines by patrolling are advisable for a number of reasons, particularly in the more thickly settled districts. It has been found that patrols made on foot are most satisfactory. The frequency of patrolling depends largely upon the design and location of the particular line and also upon its importance.

With frequent regular inspections, the possibility of wire failures is considerably reduced, patrolmen often detecting burned spots on the wire caused by flashovers which later, particularly in the strain of the cold weather, will undoubtedly result in transmission line failures.

The elimination of tree conditions is another factor which should be given careful attention, proper pruning of trees is necessary and in some cases their removal is desirable. A close watch should also be kept for the possibility of people either erecting or moving buildings under the lines, as persons engaged in this work often do not realize the danger from high-tension wires. All such matters can be watched closely by the man who is constantly covering the line. The patrolman becomes more or less acquainted with all of the people living along the line and is able to impress upon them the possibility of danger from carrying on such work. This generally results in the patrolman being advised when matters of this kind are contemplated; thus arrangements can be made for a prearranged interruption of the line, if necessary, while the work is in progress.

In addition to the regular patrols of transmission lines, it is thought quite desirable to institute special patrols after a transmission line has been exposed to severe storms or when transmission lines have shown indications of trouble and have been returned to service without the fault being discovered.

On some systems it has been found desirable to carry on practically continuous testing of transmission-line insulators and in so far as the older insulators are concerned, this is still in most cases necessary.

Improvements which have been made by the manufacturer from lessons learned by experience in the field has produced an insulator which has an extremely low rate of deterioration for at least a period of from 10 to 12 years. While it is, of course, necessary to watch the insulators during this time, it is not thought so vital that they be continually tested.

Various kinds of tests have been in use but it now appears that the 60-cycle, high-voltage test is the most satisfactory.

In order to constantly improve the operation of generating plants and to increase the output of hydroelectric plants, an adequate system of station records must be maintained. Each station should be supplied with log books in which is recorded all operations which are carried out, also information relative to conditions leading up to each operation. Where operations are performed under instructions from foremen or supervisors, a notation should be made indicating from whom these instructions are received. These log books are

very useful in making studies of past operations and in showing how improvements can be made.

Rain gages should be maintained at each station in order that records of precipitation may be kept. These records are sometimes taken in cooperation with state authorities, in which case they become official government records. These records should be compared with run-off so that probable hydroelectric outputs can be estimated in advance. After heavy rains or in advance of spring floods, reservoirs can be so drawn down that the maximum amount of excess river flow will be utilized.

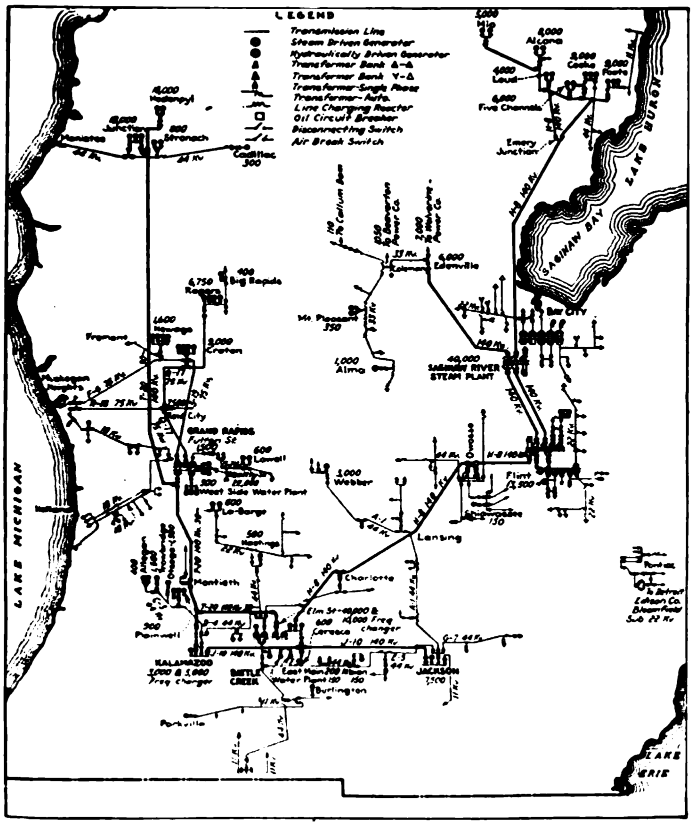

FIG. 2—MAP OF CONSUMERS POWER COMPANY SYSTEM

It is necessary that operators of these systems be constantly on the alert to detect any weaknesses which may be developing—thus faults may be detected before they have interfered with service. In order to accomplish this an adequate system of inspection and tests must be maintained.

Adequate means of communication between stations and the load despatching department is quite necessary for economical operation and in emergencies will assist, by locating faults and transmitting switching orders, in restoring service with the least delay.

An identification scheme for lines and switches will greatly facilitate transmission of orders and avoid mistakes. This scheme should consist of symbols which are not easily confused in discussion over telephone lines. This will avoid the possibility of incorrect operation of switches.

One of the very essential factors necessary for successful and economical operation is an adequate load despatching system. Such a department should be furnished with information showing efficiencies of both hydroelectric and steam generating units at different loads, delay of water between plants in series on the same river, rate of run-off from precipitation, relative storage above hydroelectric plants so that sufficient water can be passed from one plant to another on the same river and thus keep them all operating at the highest efficiency. The men must be kept acquainted with the loads to be carried and with any unusual conditions which will affect hour-to-hour operation. It is desirable to have these men acquainted with the condition of equipment in all the plants with reference to its ability to carry load; no apparatus affecting the capacity of any of the plants should be taken out of service without the advice of this department. Station operators should supply the load despatchers with frequent operating reports so that loads can be adjusted between plants and at the same time make sure that sufficient excess capacity is in service to take care of emergencies.

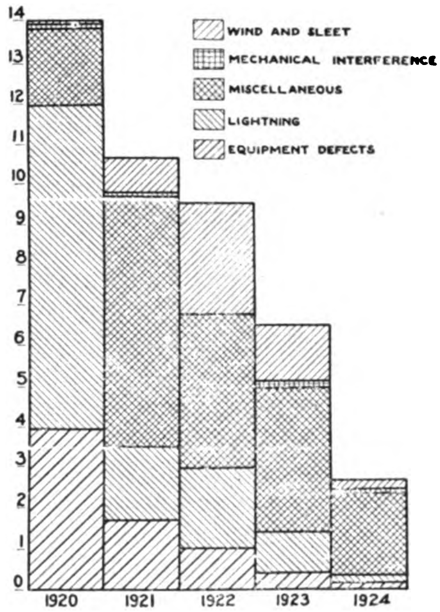

FIG. 3—CHART SHOWING COMPARATIVE REDUCTION OF TRANSMISSION-LINE INTERRUPTIONS

Some means is necessary to give the load despatcher a visual record of the position of switches. A method which has been used instead of the more elaborate electrically operated device is a small board consisting of a single-line diagram of the system laid out geographically, mounted on a thin wooden panel, backed by a bank of red lamps. Small holes of about 3/16-in. diameter are drilled through each switch location. Rubber plugs that can be readily pushed through and out of the holes with the point of a pencil are inserted in the holes to represent closed switches. The open

holes allow the red light to show through, representing open switches.

Each station should be provided with written instructions covering emergency operation of switches and lines—thus in case telephone communication is interrupted, operation can continue and interrupted service be restored.

The author has based many of his conclusions on the results of his experience with the system of the Consumers Power Company of Michigan, which has had to confront many of the problems to be considered. Fig. 2 is a map of this system showing 600 miles of 140-kv. transmission lines suspended in the form of a "U." There are 1100 miles of transmission lines from 22-kv. to 75-kv. in addition to the 140-kv. backbone connecting 44-steam and hydroelectric generating plants with distribution centers consisting of several moderate sized cities and a larger number of towns and villages. The west side is made up of 30-cycle equipment and the east side, 60-cycle, connected together at two points with 5000-kw. and 10,000-kw. frequency changers.

The extent to which these facilities can be made workable and the results which can be obtained are indicated to some extent by Fig. 3, showing the relative improvement of transmission-line operations with reference to interruptions to substation supply, involving lines of 22 kv. and above, including the transmission line itself and associated high-voltage apparatus in stations and substations. All interruptions are evaluated on a kv-a-mile-a-minute basis.

The causes are divided into five groups; Lightning, Wind and Sleet, Mechanical Interference, Equipment Defects and Miscellaneous. The mechanical interference group represents trouble due to foreign objects blowing into lines, automobiles and trucks leaving the road and striking poles and towers, and other similar troubles.

The miscellaneous group includes testing and inspection, interruptions necessary to take care of construction and maintenance work, unknown causes and mistakes. Prearranged interruptions to take care of construction and maintenance work represent about 90 per cent of this group. The continuing reduction in the interruptions from all causes shown by these graphs brings out clearly the improvement that is being made in both operation and design.

STREET LIGHTING BEGAN IN 1414

Street lighting began in 1414 when a city ordinance in London required every house and store owner on certain streets to hang out at least one horn-sided lantern at sunset. Paris, in 1558, led the world in municipal street lighting when it installed tall vases at important street corners in which pitch was burned each night with flickering, sooty results. These various crude outdoor lighting methods strove ineffectually for more than 450 years to achieve what the electric carbon and filament lamps have done in the last 40 years.

Discussion on Alternating-Current Analysis

ALTERNATING-CURRENT ANALYSIS[1]

(R. D. Mershon)

V. Bush (Communicated by letter): The total power in any network must evidently be supplied by the source. Similarly the algebraic sum of the separate reactive kv-a. in the separate branches must also be supplied from the source as excitation to the system. This applies to a system in which all voltages and currents are of the same frequency, irrespective of how the system may be interconnected. It is a very useful principle, and I have been using it with classes at the Massachusetts Institute of Technology in the form given by Dr. Mershon, since he first called it to my attention sometime ago.

Another way of looking at the matter is this. Again dealing only with a single frequency: the excitation or quadrature kv-a. which must be supplied is given by the amount of iron or air carrying flux, the permeability of the iron, and the flux density; and on the other hand, the amount of stressed air or dielectric, the dielectric constant, and the electric flux density. Specifically the net excitation, to be derived from rotating machinery, is given by the difference between the stored magnetic and electric energies, or

$$\int \left(\frac{B^2\, d\, v}{8\, \pi\, \mu} - \frac{E^2\, d\, v}{8\, \pi\, K} \right)$$

a volume integral. This is entirely independent of how the system is connected, the number of phases, and so on. In other words, if a certain weight of iron of known permeability is to be excited to a definite flux density, the excitation kv-a. requirement is the same no matter where the iron is placed or how related to the circuit. Also the contribution of the dielectric toward this excitation depends only on how much there is of it, its dielectric constant, and how high it is stressed.

It is a somewhat different matter when we consider the iron to be of varying permeability. There are then always harmonics introduced either in voltage or current, but not necessarily in both. It would seem that the amount of these harmonics should, in some fundamental way, depend upon the amount of iron present, its hysteresis loop and its maximum flux density, independent of the circuit connections. However, such a general principle is not available, largely because there is no ready way of specifying what is meant by the amount of harmonics present in the network. If such a conception could be arrived at in useful manner it would enable us to treat the harmonics produced by transformer banks with somewhat the same facility that the present principle affords for the computation of the apparent power of the network.

H. H. Race (Communicated by letter): In the recent paper on "Alternating Current Analysis" presented by Mr. Mershon he claims that the material he covered had not previously appeared in print. This has been taught for years as an elementary method for the solution of such problems and may be found in several much-used Electrical Engineering text-books.

My first reaction to Mr. Mershon's paper was to wonder why he should present the old long-hand method for the solution of such circuits, why he should prefer to use long expressions involving squares and roots in preference to representing vectors and operators by complex numbers.

Then I asked myself the opposite question, what advantages would result from the solution of such circuits using complex numbers. There are at least three:

(*a*) *The use of complex numbers allows the solution to be carried through in short symbolic equations.* The advantage of this would be much more apparent if Mr. Mershon had chosen circuits having more combinations of series and parallel circuits than he has shown. His equations are very unwieldy and would become much more so if the circuit were made more complicated.

1. A. I. E. E. Journal, January 1925, p. 43.

In symbolic form the total current in Fig. 3 may be obtained as follows:

$$i = \frac{e}{Z_{total}} = \frac{e}{Z_{12} + Z_{23}} = \frac{e}{\dfrac{1}{Y_1 + Y_2} + \dfrac{1}{Y_3 + Y_4}}$$

where Z and Y represent respectively the complex expressions for the impedance and the admittance of the branches denoted by their subscripts.

Compare this with equation (19) and we see that his C is the equivalent impedance of the whole circuit, although he does not call it such. If one were to solve the symbolic equation above, the actual computations necessary would be the same as those required for the solution of equation (19) but how much easier it is to obtain an expression for the current by the symbolic method.

(*b*) *A solution expressed in simple symbolic equations makes much more apparent the steps involved when one person is trying to understand the work of another.* This is important, else what is the use of engineering literature.

(*c*) *The use of complex numbers by engineers should be encouraged rather than discouraged* because so many problems are easily solved by their use, which are exceedingly laborious, if possible at all, using the long-hand method. For example, consider circuits having distributed constants.

Discussion at Midwinter Convention

TRANSMISSION SYSTEMS WITH OVER-COMPOUNDED VOLTAGES[1]

(Dwight)

New York, N. Y., Feburary 8, 1926

L. F. Woodruff: One of the chief problems encountered in the calculating of the most advantageous amount and phase of compounding for the generator-end voltage of a transmission line is the determination of the settings required to locate the receiver power circle center at a predetermined point. This problem is more involved than that of finding the center of the circle for given regulator settings, and while it is possible of explicit solution, such a solution is so cumbersome and involved that it is practically useless. Yet the logical approach to the problem is to try different circles of load power until the one is found which affords most economical operation, considering line and transformer losses, synchronous reactor losses and costs, voltage rise on the line, and stability. Then, having located the circle from economic considerations, the problem becomes that of finding the regulator settings required to make this the operating circle of the system.

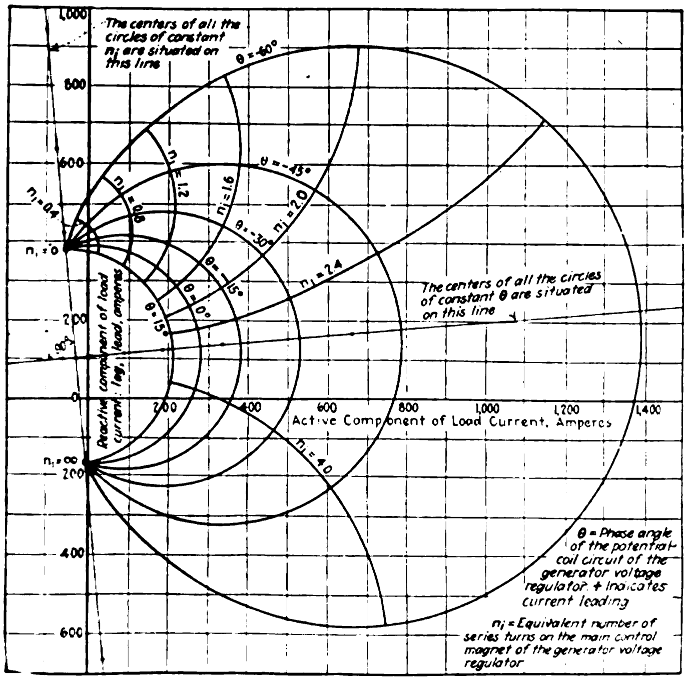

Fig. 1—Chart Showing Amount and Phase of Compounding at Generator End Required to Locate the Center of the Load Current or Power Circle at Any Desired Point. Load Voltage is Constant

Mapping of Power Coordinate Plane to Show Effect of Various Degrees of Compounding. I have found that the best method of solving this last problem is to draw on the load-power coordinate scale curves which map out the region in which the center is to be located in terms of parameters which indicate the amount of compounding. Certain features of these curves render their calculation and construction very much simpler than is at first apparent.

Fig. 1 herewith shows the amount of compounding required to locate the center of the load-power circle at any desired point, for a transmission circuit consisting of a 250-mi. line with terminal transformers. This figure has already been published[2], and the details of line, transformer and regulator constants may be found in the original references. In connection with it now I wish to point out these facts:

1. The center of the load-power circle, with constant load voltage and with generator voltage compounded, may be located anywhere on the chart.
2. For a given amount of compounding, the location of the center depends largely on the phase of the compounding.

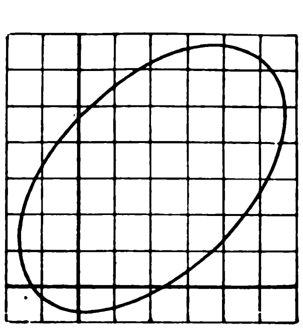

Fig. 2—Original Ellipse Diagram of Power at Load End of Line with Voltage Componded at Both Ends

3. The curves of constant amounts of compounding, but various phase angles, comprise a family of circles whose centers, for a constant load voltage, all lie on a straight line passing through the center of the circle diagram for ordinary constant-voltage operation, and another point in the third quadrant corresponding to theoretically infinite compounding. The curves of constant phase angle, but varying amounts of compounding, comprise another family of circles passing through the two points just mentioned. The phase of the compounding can be adjusted by putting a reactance and resistance in series with the potential coil of a voltage regulator, instead of only a resistance, and while this has not been done in practise, it offers opportunity of improvements in line control.

1. A. I. E. E. Journal, January, 1926, p. 25.

2. L. F. Woodruff. Regulator Settings for Long Lines, *Elec. Wld.* 1924. Also, Principles of Electric Power Transmission (Wiley), 1925.

Voltages at Both Ends Compounded—Load Power Ellipse Transformed to Circle. Since graphical methods are so advantageous in shortening or eliminating calculation, and since the main advantage of circle diagrams over others which could present the same information lies in their easy preparation, a method of transforming the "ellipse diagram" which Professor Dwight derived, into a circle diagram, should be of some interest and value.

Fig. 2 represents an ellipse diagram plotted on rectangular axes. To transform this to a circle diagram, let one of the scales be such as to make the major axis of the ellipse lie along the 45 deg. line, unless it already conforms to this condition.

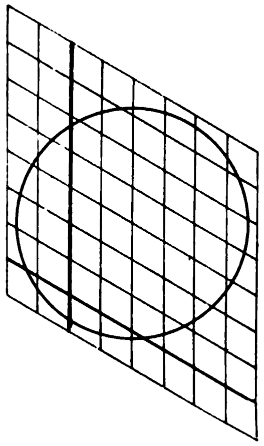

Fig. 3—Ellipse Diagram of Load Power Transformed to a Circle Diagram by Skewing the Axes

If the original angle of this axis with the horizontal is θ degrees, the change to 45 deg. may be accomplished by using a vertical scale equal to the horizontal scale multiplied by tan θ. Now suppose the major and minor axes of the new ellipse to be of lengths A and B respectively. By skewing the axes as shown in Fig. 3, so that the angle between them in the first quadrant is 2 $\tan^{-1}\left(\frac{A}{B}\right)$, the ellipse is transformed into a perfect circle, and so may be drawn at once with a compass.

CURRENT LIMITING REACTORS WITH FIRE-PROOF INSULATION ON THE CONDUCTOR[1]

(Kierstead)

New York, N. Y., February 9, 1926

V. M. Montsinger: The general tendency today is to make all electrical apparatus as fool-proof as possible. This is especially true of apparatus applied to protect other apparatus. In other words when the safety of other apparatus worth many thousands of dollars is dependent upon the proper functioning of a reactor it becomes doubly important to make the reactor as nearly perfect as possible. Mr. Kierstead's paper shows a marked advance in the art of making a dependable current-limiting reactor.

I well remember some of the early designs a few years ago, which were built by spacing bare copper cables by means of wooden supports notched to hold the conductors in place. Obviously a reactor having its turns supported by a combustible material, like wood, would not stand a very high temperature on short circuit, certainly not over 150 to 175 deg. cent. It was soon realized that a reactor of this design would not meet the severe conditions demanded of it. When the cast-in concrete type was developed and perfected it was thought that the problem of building a perfect reactor was solved.

But it was not long before someone left a bolt or a nut near a reactor and when a short circuit came on, the loose metal was drawn into the reactor by the magnetic forces set up, and the reactor failed to perform its function. A new problem had appeared which must be solved. This problem was not an easy one to solve because it was a difficult matter to obtain an insulation with sufficient toughness to resist the cutting or bruising action of a bolt hurled against it and at the same time to withstand a temperature of 300 to 400 deg. cent. without becoming charred. Some of the early forms of asbestos insulation were not satisfactory because they contained an appreciable amount of cotton, which soon burned out and weakened the fabric. Mr. Kierstead's efforts have succeeded in obtaining practically a 100 per cent asbestos insulation which is entirely satisfactory and we now have once again a reactor which appears to be practically perfect.

It is to be hoped that operating engineers who are dependent upon these reactors to protect large and expensive apparatus will appreciate Mr. Kierstead's efforts in producing a product so nearly proof against failures.

S. I. Oesterreicher: While I am in hearty agreement with many of Mr. Kierstead's statements regarding the insulation of current-limiting reactor conductors, still I regret very much not being able to give him full credit for his interesting conclusions.

As far as covering of reactor conductors is concerned, originality belongs to Mr. Philip Torchio and Mr. H. R. Woodrow. As far back as 1912, these two gentlemen designed and put in service current-limiting reactors in which the conductors were insulated partly with asbestos and partly with a rubberized tape.

Due to the increased generator rating and voltage of the circuit on which some of these first reactors were installed, they became obsolete and we had occasion to dismantle and inspect them.

On some of them the insulation after about 12 years of service was not impaired in the least and would have been good for many more years of service.

There is no question in my mind about the necessity of covering the reactor conductor with an insulation if reliability is sought. I believe that under normal operating conditions, if foreign materials are dropped or drawn into a bare conductor of a reactor, the effect will be far more serious than Mr. Kierstead states. If reactor turns or layers are short-circuited within the reactor, they act as secondaries in a transformer and the currents in the two circuits are inversely in proportion to the number of turns in these circuits. Therefore, the heating due to the increased currents in the short-circuited sections will make itself manifest in a very short time and greatly to the detriment of the reactor.

Mr. Kierstead attaches great importance to the absolute fire-proof quality of the insulation upon the reactor conductor. He gives data of tests carried up to 350 deg. cent. without any distress of the asbestos insulation.

However, the limitation of an arrangement as Mr. Kierstead describes it is not the absolute fire-proof construction but the fact that the temperature coefficients of expansion between copper and concrete are so greatly different and the temperature stresses caused by the copper in the concrete so out of proportion that cracking of the concrete starts long before any shortcomings of the insulation becomes dangerous.

We have in operation throughout the country over 2500 reactors with all kinds of fibrous insulations and do not seem to have trouble on account of the kind of insulation over the conductor.

I do agree with the statement that the insulation should be mechanically strong to be able to withstand injury. From time to time, we have received complaints from one or another of our clients that suddenly a reactor started to rattle. Investigation proved that in practically all cases the trouble was due to foreign bodies becoming lodged in the reactors.

Thus, it would seem that as long as the reactor conductor insulation has ample dielectric and mechanical strength it is only a convenience of design or cost as to what kind should be used.

A. E. Kennelly: In connection with Mr. Kierstead's paper, it may be worth while to point out what is certainly known although not perhaps very generally known, that in a uniform magnetic field, parallel lines of magnetic force so to speak, a small

1. A. I. E. E. Journal, February, 1926, p. 137.

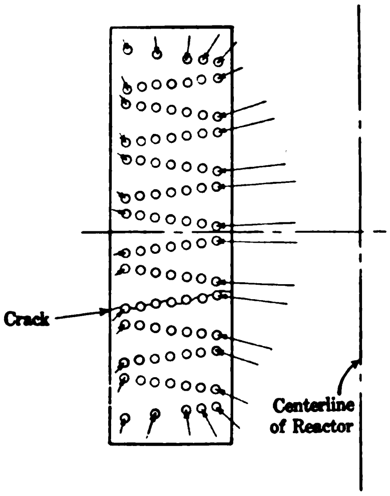
sphere of iron or steel is not subjected to any mechanical pull. That is contrary to popular belief on that subject. If a small sphere of steel is supported in a uniform magnetic field, no matter how strong the field, it will pull one way as much as the other. But if the magnetic field, instead of being uniform, is divergent in one direction, or convergent in the other, then the ball of iron or steel inserted in the field will be pulled in the direction of convergence and the pull is proportional to the flux density and to convergence. Mathematically it may be expressed as proportional to $B \cdot \frac{dB}{dc}$

W. W. Lewis: Reactors as well as other apparatus have their share of failures; some of these in the past have been due to mechanical weakness, others have been attributed to high voltage and others to so-called foreign metallic material.

The theory of foreign material has been amply substantiated in practise. In one installation 9 reactor failures occurred. Inspection after the first and last of these disclosed nails lying across some of the turns. In two other cases the reactors had been previously damaged. In the five other cases no definite cause was found for the failure. After the first failure, however, a quantity of bolts, nuts, washers and nails was cleaned out of the reactors. It may well be that some of these articles were missed in the inspection as indicated by the nail found after the last failure.

It seems obvious that live conductors so closely spaced as in reactors, are a menace to operation if left uninsulated and Mr. Kierstead is to be commended for removing this source of trouble.

F. H. Kierstead: Mr. Oesterreicher is correct in his statement that when the conductor is raised to 350 deg. cent. the concrete may crack, but his inference that failure of the reactor follows this cracking is not correct. The magnetic field of the reactor exerts a force on the winding that is transmitted as a compressive force on the concrete which forces the cracked surface closer together as is indicated in the illustration shown



SECTION THROUGH A REACTOR, SHOWING HOW THE MAGNETIC FORCE EXERTS A COMPRESSIVE STRESS UPON THE CONCRETE

herewith. Because of this fact the reactor continues to perform its function just as well after the concrete has cracked as before. The principle involved here is very much the same as that in a reenforced concrete building. The concrete of a building cracks due to expansion and contraction but it causes no concern because its compressive strength is not impaired by the cracks while the steel reenforcing resists the tension forces. The two cases are similar except that in the reactor the forces are all compressive and thus the reenforcing steel is not required.

These statements have been verified by twelve years of experience with this type of reactor in service.

TEMPERATURE RISE AND LOSSES IN STRUCTURAL-STEEL MEMBERS EXPOSED TO THE FIELDS FROM A-C. CONDUCTORS[1]

(SCHURIG AND KUEHNI)

NEW YORK, N. Y., FEBRUARY 9, 1926.

H. C. Forbes: Engineers who have been concerned with the layout of isolated-phase generating stations will be especially interested in the paper of Mr. Schurig and Mr. Kuehni. In general, this type of station construction is likely to lead to a condition such that heavy currents will be flowing through a bus bar which may be in fairly close proximity to the steel work of the station while the return circuit for this current is comparatively remote.

Some tests were made by The New York Edison Company to determine how serious the heating might be under these conditions and to ascertain what measures might be taken to reduce it. The results of these tests are too voluminous to be presented in their entirety, but it may be of interest to discuss some of them and to note the agreement with those given in the paper.

The structure tested was a rectangular steel loop about 6 in. by 10 in. Tests were made with the current-carrying conductor passing through the closed loop and then were repeated with one side of the loop removed and finally with the conductor passing at right angles to a single member of the loop.

It was found that with the conductor approximately 30 ft. from the steel work, the loss in the case of the single member was about 60 per cent of the loss under similar conditions with the loop completely closed. If the steel loop were larger, this difference would undoubtedly become less pronounced and for the construction used in most generating stations, the losses and resultant heating would be largely independent of whether or not the steel work formed a closed loop around the conductor. The temperature rise in the members would depend chiefly upon the proximity of the conductor, and the value of the current flowing.

Most of our tests were made at 60 cycles, but a few comparative tests were made at both 25 and 60 cycles. These gave a ratio of temperature rise of about 1.7 which I would consider a very good check on the value of 1.6 as given in the paper, particularly in view of the limited number of our own tests covering this point.

It was realized that the losses might be reduced by putting short-circuited copper turns around the steel members and tests showed that such a loop, when placed around the steel member at the point nearest the conductor, reduced the losses by 40 per cent in the case of a single steel member at right angles to the conductor and 60 per cent in the case of the closed steel frame. The use of more short-circuited loops than one at the point nearest to the conductor gave but little further reduction in the losses.

It appears from the tests which have been made that some caution should be observed in station design to avoid heating in the steel work and the paper which has been presented will serve as a very valuable guide. However, if care is taken to place conductors which are to carry heavy currents, say from 2500 to 4000 amperes at a distance of 2.5 ft. or more from the steel work, the heating will not ordinarily be serious and it is doubtful if the use of short-circuited copper loops would be justified.

A. E. Kennelly: We know that such physical conditions as described in this paper are very complicated and that it is very difficult to find a simple formula to cover a great range of such multitudinous conditions, but the practical way in which the results are tabulated and indicated seems of great value.

O. R. Schurig: I agree with Mr. Forbes that for spacings

1. Abridgment, A. I. E. E. JOURNAL, May, 1926, p. 446.

as large as 2.5 ft. between conductor and iron members crossing the conductor the temperature rise in the iron may be expected to be only a few degrees for currents of the order of 3000 or 4000 amperes even if the return conductors are quite remote as in isolated-phase construction. That follows from the curves shown in the paper and there is good agreement on this point as well as on the others brought out by Mr. Forbes. Also let me say that it would help a great deal if data obtained by the operating companies could be published in the discussion of this paper or in separate papers. Doubtless a good deal of the work we did could have been saved if the data and experience of other investigators had been available. We certainly hope such information will be published.

We agree with Professor Kennelly that the calculations from the dimensions and physical constants are very complicated and probably not practical at the present stage. However, efforts would doubtless be productive of good results in the course of time. This problem may be a good one for some of the college research laboratories

NO-LOAD COPPER EDDY-CURRENT LOSSES[1]

(SPOONER)

NEW YORK, N. Y., FEBRUARY 9, 1926

W. J. Foster: I am interested in this paper on the eddy-currents that exist in the copper on open circuit. A very easy way of determining these losses is to make a core-loss test before the machine is wound. Sometimes it interferes with production if a commercial machine is used. Occasionally it happens that a test has to be made at the factory on a machine which is to be shipped that involves knocking it down. In such a case, the core loss can be run off with the machine completely assembled, then after the winding is removed from the armature, it can be repeated.

I notice the author shows reasons why eddy losses exist in the slot, the cross fluxes changing as the rotor advances, etc. There are also conditions at the head of the armature due to the fringing of the flux that are responsible for some losses.

I remember in the case of a few machines many years ago learning something about how to sectionalize conductors by making use of different windings in the same machine, and finding quite a difference in the open-circuit core loss. Possibly others have had similar experiences.

In the matter of determining the losses, as Mr. Dawson and Mr. Barns have described, I believe their method to be about the only feasible method for certain large enclosed machines. However, we must look out for a number of things;—such as the specific gravity of the air. There is the matter of radiation. If it is a very high-speed machine, occupying small space, probably we can entirely neglect the heat that passes off by radiation, but in the case of slower-speed machines that occupy large space and have very large surfaces, some allowance should be made.

P. L. Alger (communicated after adjournment): It has been my opinion for some time that a large part of the observed core loss in a squirrel-cage induction motor is due to circulating currents in the squirrel-cage bars caused by the pulsations of flux in the rotor teeth. These pulsations are due to the variations of reluctance caused by the stator teeth, and are especially large when open slots are used in the stator. Also, these pulsations in the rotor teeth are very large when the ratio of rotor to stator teeth much exceeds unity, they are negligible when the ratio of slots is nearly equal to one, and they are fairly large when the ratio is considerably less than unity, but greater than one-half.

As I understand it, Mr. Spooner now suggests that the loss due to these pulsations of flux in the rotor teeth is not so much due to the circulating currents induced in the winding as to the eddy-current losses produced by the flux forced across the slots as a result of saturation of the teeth. Of course, the flux across the rotor slots is the same when a given number of ampere-turns are present, whether due to current in the rotor bars, or due to saturation in the rotor teeth, other things being equal. Thus, whether the pulsation of reluctance, due to the stator teeth, is counterbalanced by eddy currents and saturation ampere-turns produced in the teeth, as is the case with an open-circuited rotor winding, or is counterbalanced by the ampere-turns of a current induced in the squirrel-cage bars, the same eddy-current loss in the copper should result. But, in the former case, the ampere-turns in the rotor teeth are produced as a result of flux pulsations in the teeth, and these pulsations must be quite large to make many ampere-turns due to saturation. And, in the other case, the ampere-turns in the squirrel-cage winding can be produced by only a small change in flux, corresponding to the voltage required to supply the impedance drop of the winding. Therefore, in the former case, the flux pulsations in the rotor are large, the ampere-turn pulsations in the rotor teeth are not large, and the reflected pulsations of flux in the stator teeth are small; while, in the latter case, the flux pulsations in the rotor teeth are small, the ampere-turn pulsations in the rotor winding are large, and the reflected flux pulsations in the stator teeth are large.

From all this, in the case of a squirrel-cage motor with straight slots and considerably more squirrel-cage bars than stator slots, there can be a very small loss of the type described by Mr. Spooner, as the saturation ampere-turns in the rotor teeth are nearly constant, except for a slip-frequency variation. Therefore, in such cases, one ought to be able to calculate the tooth-frequency core loss as the sum of the pole-face loss, the copper loss in the rotor bars due to the induced currents based on the high-frequency bar resistance, and the flux pulsation loss produced in the stator as a result of the induced rotor currents. Hence, I came to the conclusion that Mr. Spooner's theory does not account for the losses in the ordinary squirrel-cage induction motor with straight slots, and, if he obtains numerical agreement between his calculations and test results, this agreement must be due in some measure to chance.

The foregoing remarks are not intended as a criticism of the paper, but as giving a line of reasoning parallel to Mr. Spooner's which should bring from him some interesting additional ideas. As far as slip-ring induction motors and direct-current machines are concerned, I think Mr. Spooner's theory should give a sound basis for core-loss calculations. It is interesting in this connection to note that, on the basis of Mr. Spooner's ideas, by using a high-grade steel in a d-c. machine, a greater core loss may be obtained than with a low-grade steel, as the extra saturation ampere-turns may cause more losses in the winding than are due to the saving in iron loss itself. On this basis, by subdividing the winding to avoid eddy currents, it should be possible to use a better grade of steel, with the result that a double gain in losses can be secured.

T. Spooner: Referring to Mr. Foster's remarks, we have tested a number of experimental and commercial machines, both d-c. and a-c., according to the method suggested by him, namely, with the windings in position in the slots and with the windings removed. The differences in losses caused by the eddy currents in the copper began to be appreciable at about 70 kilolines per sq. in. mean-tooth induction for induction motors and at about 120 kilolines per sq. in. for salient-pole machines. Often the test losses check the calculated losses quite closely, but sometimes there are rather wide differences. For small-diameter machines where there is considerable tooth taper, it is sometimes difficult to estimate accurately the slot leakage fluxes. This is perhaps one of the chief causes of the observed discrepancies.

We have made no investigation of losses caused by leakage fluxes in the neighborhood of the end windings.

1. A. I. E. E. JOURNAL, March, 1926, p. 264.

Because of the following considerations, I am unable to agree with Mr. Alger's line of reasoning in connection with the eddy-current losses in the rotor bars of squirrel-cage induction motors. In other words, I am still convinced that there exist eddy-current losses in the squirrel-cage bars, after connecting the end rings, which are equal to or greater than those which exist with the bars open-circuited.

Suppose we consider two adjacent teeth, No. 1 tooth having a smaller air-gap reluctance than No. 2 tooth at a given instant. Now, with the bars open-circuited, flux will flow across the slot through the bar from tooth No. 2 to tooth No. 1, giving radial and tangential components of leakage flux. If now the bars are short-circuited, sufficient current will flow in them to bring the mean flux in tooth No. 2 nearly up to that in No. 1. Since the fluxes in the two teeth are practically equal but the air-gap for one of these is less than for the other, the m. m. f. acting on tooth No. 2 must be greater than that acting on No. 1. In other words, the current in the bars will decrease the m. m. f. acting on tooth No. 1 and increase the m. m. f. acting on tooth No. 2. The tangential slot-leakage flux should therefore be increased toward the top of the slot and decreased toward the bottom, the total remaining about constant. At the same time the radial slot leakage flux will be decreased on the side toward tooth No. 1 and increased toward tooth No. 2.

High-frequency circulating currents in squirrel-cage windings, assuming an effective resistance as calculated by Field's formula, do not, in the cases which I have observed, account for the increased losses due to the presence of the copper bars unless the pulsation losses in the stator teeth due to the high-frequency circulating currents in the rotor windings are much greater than those which existed in the rotor teeth before closing the squirrel-cage windings. This seems improbable since the pulsation losses with closed squirrel-cage windings show no tendency toward decreasing as the induction increases due to tooth saturation, as would be the case if they were due to high-frequency iron losses in the stator teeth.

Mr. Alger's point concerning the danger of using high-silicon steel for the cores of machines operating at high-tooth inductions is well taken. Since at high inductions the permeability of 4 per cent silicon steel may be from ½ to 1/3 of that of low-silicon steel, the slot-leakage fluxes will be greatly increased for the former. Since the eddy-current losses increase as the square of the slot-leakage fluxes, the substitution of high- for low-silicon steel may increase very considerably the copper eddy losses. The remedy is, of course, a greater subdivision of the copper, as suggested by Mr. Alger.

HEAVISIDE'S PROOF OF HIS EXPANSION THEOREM[1]

(M. S. Vallarta)

New York, N. Y., February 11, 1926

J. J. Smith: I should like to refer to the paragraph third from the end of Mr. Vallarta's paper in which he states that Heaviside gave another alternative proof of his Expansion Formula. This is given in Heaviside's Electrical Papers, Vol. II, p. 226, in a footnote. As this seems to be another very important way of proving the expansion theorem, I shall take the liberty of quoting it in full, as follows:

Let

$$C = \frac{f(p_0)}{\phi(p_0)} E \tag{1}$$

be the differential equation connecting C with E where p_0 stands for d/dt and $\phi(p) = 0$ is the determinantal equation of the system, that is, $\phi(p)$ may be either the characteristic function in fully developed form, or the same multiplied by any function which does not conflict with its use in the determinantal equation. Then we have by the algebraical theorem:

$$\frac{1}{\phi(p_0)} = \sum \frac{1}{(p_0 - p)\,\phi'} \tag{2}$$

where ϕ' means $d\phi/dp$, and the summation includes all the roots of $\phi(p) = 0$. Therefore, by (1), using (2) and integrating:

$$C = f(p_0) \sum \frac{E}{(p_0 - p)\,\phi'} = E f(p_0) \sum \frac{e^{pt} - 1}{p\,\phi'} \tag{3}$$

E being zero before and constant after $t = 0$. But also by (2):

$$\frac{1}{\phi_0} = \sum \frac{1}{-p\,\phi'} \tag{4}$$

where ϕ_0 means ϕ with $p_0 = 0$, so that (3) becomes:

$$C = E f(p_0) \frac{1}{\phi_0} + E f(p_0) \sum \frac{e^{pt}}{p\,\phi'} \tag{5}$$

Now, perform the operations indicated by $f(p_0)$ and we get:

$$C = E \frac{f_0}{\phi_0} + E \sum \frac{f(p)}{p\,\phi'} e^{pt} \tag{6}$$

where f_0 means f with $p_0 = 0$. (See also the investigation at the end of the (later) paper on "Resistance and Conductance Operators.")

(6) is the form of the expansion theorem given by Heaviside in his Electromagnetic Theory, Vol. II, p. 135, a modified form of which is given on p. 127.

On going through the second volume of the Electromagnetic Theory, it is, I think, fairly evident that Heaviside used the above conception of the expansion theorem quite freely. For instance, on p. 88 he solves the problem of voltage applied at one end ($x = 0$) to a cable of length l which is grounded at the other ($x = l$) and for which the well-known formula is:

$$V = \frac{\sinh q\,(l - x)}{\sinh q\,l} E$$

By expanding

$$\frac{q\,l}{\sinh q\,l} = 1 - \frac{2}{1 + \left(\frac{\pi}{q\,l}\right)^2} + \frac{2}{1 + \left(\frac{2\,\pi}{q\,l}\right)^2} - \frac{2}{1 + \left(\frac{3\,\pi}{q\,l}\right)^2} \cdots$$

where

$$q = \sqrt{C\,R\,\frac{d}{d\,t}}$$

and then identifying

$$\frac{1}{1 + \dfrac{n^2\,\pi^2}{R\,C\,l^2\,\dfrac{d}{d\,t}}} \text{ with } e^{-\frac{n^2\pi^2 t}{RSl^2}}$$

the solution of the problem is readily obtained.

If his work in this example is carefully followed out it will be found that he is doing nothing but developing the various steps in the expansion theorem given in the footnote in his Electrical Papers, p. 226.

There are two fundamental concepts back of this derivation which it may be interesting to examine. Writing (1) in the form:

$$\left(A_n \frac{d^n}{d\,t^n} + A_{n-1} \frac{d^{n-1}}{d\,t^{n-1}} + \ldots\ldots + A_1 \frac{d}{d\,t} + A_0\right) C = f(p_0)\,E \tag{7}$$

where the actual value of $\phi(p_0)$ is inserted, it may be seen that this is a linear differential equation of the nth order for C. Now it is known that the general solution of this equation is:

$$C = B_1\,e^{p_1 t} + B_2\,e^{p_2 t} + \ldots\ldots + B_n\,e^{p_n t} + \frac{f(p_0)_{\,p_0 = 0}\,E}{A_0} \tag{8}$$

1. A. I. E. E. Journal, April, 1926, p. 383.

where $p_1, p_2 \ldots\ldots p_n$ are the roots of the equation

$$A_n p^n + A_{n-1} p^{n-1} + \ldots\ldots + A_1 p + A_0 = 0$$

Each term $e^{p_r t}$ is a solution of the equation

$$\left(\frac{d}{dt} - p_r\right) y = 0$$

We are thus lead to expect that the solution of a linear differential equation of the nth order can be made to depend upon the solution of n linear equations of the first order, and if a comparison is made of equations (1) and (3) it will be seen that the equation of the nth order in (1) has been transformed into n equations of the first order in (3) by means of a partial fraction expansion.

The second point to notice is that nowhere in the above proof does Heaviside use the property $C = 0$ when $t = 0$. What he does postulate is that E is zero before and constant after $t = 0$. It is under this hypothesis that in order to find the value of $\frac{1}{p_0 - p}$ he assumes it to be say y, then

$$(p_0 - p)\; y = E$$

Or

$$\left(\frac{d}{dt} - p\right) y = E$$

giving

$$y = i_0\, e^{+p(t - t_0)} + \frac{E\,(e^{pt} - 1)}{p}$$

Now in all practical problems the real part of p is negative, corresponding to circuits with resistance in which energy is dissipated; hence, whatever current may have existed at the instant $t_0 < 0$, where the actual value of t_0 may be made as large as we please, it will have become negligible by the time $t = 0$. Hence, the effect produced by the applied voltage E is contained wholly in the second term, giving

$$y = 0 \qquad t < 0$$

$$y = \frac{E\,(e^{pt} - 1)}{p} \qquad t > 0$$

Or, if we wish to put it another way, the y caused by E applied at $t = 0$ is given by this term, and the $i_0\, e^{p(t - t_0)}$ part is due to another cause. This is not the way in which Heaviside makes this particular step but the results are the same.

Whatever way we chose to look at it, the facts are that by using this substitution in (3) as shown, and completing the solution as in (6), we get the solution of (1), corresponding to the system (assumed to be a dissipative one) represented by (1) being at rest, and having been at rest for a very long time prior to $t = 0$. We have thus used the one condition

$$E = 0 \qquad t < 0$$

$$E = E \text{ constant} \qquad t > 0$$

to supplant the n terminal conditions which would be normally required to determine the constants in the solution of (1) or (7). The economy in such a reduction of terminal conditions should be apparent. The economy becomes more apparent when applied to problems in long transmission lines where an infinite number of terminal conditions arise in certain methods of obtaining the solution.

I presume the reason Mr. Vallarta did not discuss Heaviside's second derivation referred to above is that it involves so-called operational mathematics, and operational methods have been looked upon with disfavor by mathematicians for many years as being lacking in rigor, which may or may not be true. I like to think, however, that between the operational mathematics and the conventional pure mathematics there must be some common ground on which they can both meet together by a little give-and-take on both sides. I have published two papers in the *Journal* of the Franklin Institute with this end in view, one in June, 1923, and the other as a serial in October, November and December, 1925. In these papers the ideas given above are developed more fully. The interesting part, however, is that although Heaviside, as far as I am aware, uses his expansion theorem only in continuous systems for one coordinate in addition to the time, such an attempted development of a common ground between pure and operational mathematics has lead to a method of solution for two- and three-dimensional problems such as occur in the flow of heat, and in addition to the solution of potential problems in electrostatics in which no time factor appears. These results come from simple extensions of the development of the expansion theorem given above, which then becomes a particular expansion theorem in a great class of expansion theorems. Reference must be made to my paper for details. However, with Mr Vallarta I join in a plea for greater study of the works of Heaviside and for the development of both his ideas and the concepts of pure mathematics to the point where they will both merge into one as I have not the slightest doubt they should.

M. S. Vallarta: In his valuable discussion Mr. J. J. Smith has already given Heaviside's second proof of the Expansion Theorem, to be found in the second volume of his "Electrical Papers" (l. c. footnote 19 of the writer's paper.) The writer did not feel that a complete account of this second method of proof was necessary partly because it has already been discussed rather thoroughly elsewhere (see for example reference 9 in the writer's paper), but mostly because it is not quite so illuminating, or important from a physical standpoint, as the first method of proof based on the conjugate theorem.

Mr. Smith raises an interesting question when he speaks of operational calculus and its relation to the Expansion Theorem. As shown in the paper, operational methods are not required to establish the Expansion Theorem in the case of no null and no repeated roots of the determinantal equation, but the use of such methods really simplifies matters considerably in this exceptional case. For purposes of technical applications, however, the writer feels that both may properly be kept separate. That operational calculus can be rigorized if the proper tools and methods of attack are used has been shown by Wiener ("The Operational Calculus" forthcoming in the *Mathematische Annalen*) and Carson (see the Bell Technical *Journal* for 1925 and 1926). Once operational calculus is rightly understood it may be applied confidently not only to engineering problems, but also to problems in pure mathematical physics where less powerful methods break down completely. As a most advanced example of this type of problems, reference is made to a paper by Born and Wiener, (*Journal* of Mathematics and Physics of M. I. T., Vol. 5, p. 84, Feb. 1926) to quote but a single example.

The great importance of the conjugate theorem has been very recently recognized by K. W. Wagner ("Der Satz von der wechselseitigen Energie" *Elektrische Nachrichten-Technik*, Vol. 2, p. 376, Nov. 1925) who also gave in this article Heaviside's first method of proof of the Expansion Theorem. This and the writer's paper were written approximately at the same time (Wagner's paper was received for publication on Nov. 9, 1925; the author's paper on Dec. 1, 1925). The present writer is glad to add this interesting reference to the list already given in the paper.

THE USE OF VIBRATION INSTRUMENTS ON ELECTRICAL MACHINERY[1]

(Ormondroyd)

New York, N. Y., February 11, 1926

W. B. Creagmile: Mr. Ormondroyd has mentioned a vibrating-reed type of instrument with one reed. The common use of vibrating-reed instruments having a series of tuned reeds along a marked scale, to measure revolutions per minute

1. A. I. E. E. Journal, April, 1926, p. 330.

and a-c. frequency, is not mentioned in the paper. The reeds of the tachometer pick up mechanical vibration from the machine to which the instrument is attached. In the frequency meter, the reeds are set in vibration by alternating current flowing through an electromagnet placed in series with resistance across the mains.

The amplitude of vibration of any reed is dependent upon the amount of vibration of the machine to which the tachometer is attached, or the voltage of the line to which the frequency meter is connected. However, speed or frequency is not read by observing the amplitude of vibration of any particular reed, but by noting which reed is in vibration. Hence, we may say that the indications of speed and frequency given by the vibrating-reed tachometer and vibrating-reed frequency meter are entirely independent of the exact amount of vibration of the machine under test or of voltage of the a-c. line.

J. Ormondroyd: On the second page of the paper, the first sentence in the section on "The Vibrating Reed" makes brief mention of the two common uses of "tuned" reeds. Since the reed tachometers and electrical frequency meters are not used primarily to study vibration, no further mention is made of them.

The amplitude of motion at the end of a reed in a Frahm tachometer can be represented by equation (15) if

$$M = M + \frac{m}{4}$$

as in equation (16). This equation shows that the amplitude on any reed will be proportional to the impressed amplitude. But it also depends on the dynamic magnification which is a function of the frequency. Fig. 11c shows the relationship between reed-vibration amplitude and impressed vibration.

The reed which happens to be at or near resonance with the impressed frequency will have its motion magnified beyond all proportion to the magnification which the other reeds experience. The magnification at resonance is inversely proportional to the damping factor C as can be seen in Fig. 11c where the effect of two different values of C is shown. Putting $\frac{\omega}{\omega_c} = 1$, in equation (15) this is shown very clearly.

The speed or frequency is read by observing which reed has the greatest amplitude. The neighboring reeds usually show some smaller amplitude while the more distant reeds have no apparent motion.

In a sense the indications of speed are independent of the exact amount of the impressed vibration. This statement breaks down at the limit where the exact amount becomes zero. If turbine manufacturers could reach their ideal of perfectly balanced spindles and field-rotors the reed tachometers would become useless.

RATING OF HEATING ELEMENTS FOR ELECTRIC FURNACES[1]

(Keene and Luke)

New York, N. Y., February 11, 1926

G. E. Luke: The equations for heat loss as given in this paper are only approximate. The heat liberated by convection varies to some extent with the position of the resistor. Its variation with temperature rise to the 1.20 power is only empirically true, but it seems to hold over a rather wide range of size and temperature. Fortunately, the rate of loss by convection is a small percentage of the total so that it does not have to be so accurately known. The accuracy of the Stefan-Boltzmann equation for radiation depends upon the correctness of the coefficient of emissivity (e). This value (e) is not constant but changes somewhat with temperature. For practical purposes it can be considered as a constant without great error.

1. A. I. E. E. Journal, March, 1926, p. 222.

Although considerable data are published regarding the rate of heat transfer from high-temperature conductors, yet few are available as to the reduction in this loss due to the proximity of other parallel conductors. At first the method of calculation as shown on Fig. 3 was used. It was recognized that this method was not rigidly correct since the intensity of the heat radiation from a point on a plane surface in any direction is proportional to the cosine of the angle that direction makes with the perpendicular. Nevertheless the approximate method gave results within 2 to 3 per cent of the true loss as determined experimentally.

It is hoped that this paper will show the fallacy of designing resistors according to the constant-current-density method or the constant-surface-loss method. Figs. 5 and 6 show that the possible rating depends largely upon the resistor arrangement.

OPERATING PERFORMANCE OF A PETERSEN EARTH COIL-II[1]

(Oliver and Eberhardt)

New York, N. Y., February 9, 1926

L. P. Ferris: I wish to ask what was the condition of the coil as regards tuning during the period covered by this paper? Was it the same or different from the tuning employed during the period covered by the authors' previous paper on this subject? If the coil remained in the condition of tuning mentioned in the previous paper, overtuned by some 23 per cent., perhaps that will explain to some extent why the coil failed to prevent the tripping of the line switch in some of those fifteen cases listed in Table I. Under this detuned condition, the coil does not limit the fault current to as low a value as it would if it were tuned more exactly. With 23 per cent. overtuning (*i. e.*, with 1207 ohms reactance), the measurements reported in Mr. Lewis' paper of 1923 indicate a fault current of about 4.8 amperes, whereas the same paper gives measured currents of approximately 2.4 amperes for the coil setting nearest resonance (982 ohms). It is conceivable that, under some fault conditions, the arc might be maintained if the current were not reduced below the first figure, but would be extinguished if the current were limited to the smaller value corresponding to exact tuning. Perhaps Messrs. Oliver and Eberhardt could say how large a factor this detuning might be in accounting for some of these fifteen cases? As brought out in the discussion of the earlier papers, it would seem desirable if the coil were operated slightly detuned, that it be operated somewhat undertuned rather than overtuned, although the direction in which it deviates from the exact tuning would not seem to affect its ability to quench an arc.

W. W. Lewis: In this country the trend of operation away from the isolated neutral and toward the grounded neutral has limited the field of the Petersen coil. Nevertheless, the report of Messrs. Oliver and Eberhardt is valuable in clearly pointing out what can be done with this device under suitable circuit conditions.

In Europe, the tendency has been to design the reactor with an iron core to operate normally off resonance, but to be pulled into resonance by saturation when one conductor becomes grounded. As an alternative, the reactance is designed to be outside a certain band on each side of the resonance condition at all times. Both of these designs are intended to prevent certain overvoltage troubles anticipated when the three poles of an oil circuit breaker do not operate simultaneously. The modified devices have found much favor and have been very successful.

W. W. Eberhardt: I shall answer Mr. Ferris' question by stating that the coil, during the period reported in this paper, was overtuned approximately 23 per cent. Towards the end of the operating period, the coil was slightly undertuned but that was after the end of the lightning season and no operating experience was obtained with the undertuned setting.

1. A. I. E. E. Journal, March 1926, p. 227

ILLUMINATION ITEMS

By the Committee on Production and Application of Light

IN ITS INFANCY

Street lighting has been a problem ever since men began to herd together in cities. At first the problem was solved by each citizen who ventured out at night carrying a lantern or hiring a link boy to carry a torch before him.

This didn't amount to much as protection from highwaymen, although it did help some in getting over, around, or through the mud puddles. During that period the easiest and most popular solution of the street lighting problem was to stay at home after dark.

By and by came oil lamps stuck on poles to help out the hand lanterns. Then gas lamps took the place of oil, and so by degrees we come to our modern age of electric lighting.

It is well within the truth to say that even in America street lighting is still in a primitive stage. We have of course our "White Way" in every city of any importance, but once outside this area the streets are often dismal and dangerous after dark. The average community seems to spend just enough on street lighting to make the darkness more confusing. There is a popular notion that street illumination costs much money, but the latest investigation shows that per capita cost is only about 75 cents a year.

Scientific and adequate street lighting is a social question of paramount importance in the modern world.

First of all we have the fact of vastly accelerated out-of-door movement among all classes of people. Shut in by day, the masses and classes alike are impelled to stir abroad at night. In the theatre and shopping district, it has become the recognized practise to make the streets as light as day. What the community fails to furnish, the stores and places of amusement make up as part of their sales and advertising budget.

Among many others there are three reasons why every city, town, and many country roads, must, from now on, be properly lighted.

First the safety, happiness and comfort of all the people demand it. Second, the enormous increase in power transportation brings us to the point where traffic growth must cease unless folks can see where they are going. This refers to pedestrians quite as much as to those in automobiles, busses and street cars. Third, according to an ancient scripture, where the carcass is, the birds will gather together. With the streets thronged at night at the centers, it means that the home streets, roads and byways will all have belated travelers at night. This brings the hold-up man and other criminals to their harvest. Good street-lighting is second only to a good police force as a crime deterrent. Men love darkness rather than light when their deeds are evil. Crime diminishes as light increases.

Recognizing the great social value of good street-lighting, the scientific and engineering resources of the leading lighting laboratories have been directed towards a solution of this problem with extraordinary success. We have the lamps and the electric energy and we know how to use both to the best advantage in street-lighting. When the people wake up to the necessity of proper street lighting, half the job will have been done.—*Light*, March 1926.

NATURAL LIGHTING

Primitive man, during many ages, found daylight ample and satisfying to all his needs. His simple arts were carried on in the open and if the glare of the mid-day sun was objectionable he sought the shade of the trees. As arts and society became more complex, housing became necessary, and this created the problem of providing adequate indoor lighting. Artificial sources were developed and electric lighting has now reached such a stage of perfection that the cost of natural, as compared with that of artificial light, has become a matter of considerable interest.

Nevertheless, natural light still has its place in industries and homes, and it will still continue to hold this place for the following reasons:

1. It is ample. In our latitude the direct solar thermal energy at noon on a clear day is close to 100 kilowatts per square dekameter, (slightly more than 1000 square feet) or sufficient to maintain 2500 forty-watt lamps, if we could utilize it, which, in the future, someone may learn to do.
2. It never fails. The sun is always shining.
3. It is the kind of light to which the human eye is best adapted, and that which artificial light tries to imitate.

An objection to natural light is that it varies in intensity. Dr. Abbot's studies indicate a variation of about one per cent on each side of the mean in recent years. This is masked, however, by a variation of $\pm$ 3.5 per cent due to the varying distance of the earth from the sun. Furthermore, the percentage of solar energy transmitted by the earth's atmosphere varies from day to day and from hour to hour, even when there are no clouds. With clouds completely covering the sky, the diffused solar energy received on a horizontal surface is about one-fourth what it is in the absence of clouds. However, even in cloudy weather, natural lighting is ample for out-door operations except during rainfall, when most out-door work ceases. In the process of evolution the human eye has learned to adapt itself without discomfort to the intense light at midday in summer and to the feeble light of twilight, or a range of intensity from 10,000 to 30 foot-candles.—*Trans. I. E. S.*

The monument erected on the site of the original laboratory of Thomas A. Edison, at Menlo Park, N. J., will hereafter be flood-lighted so as to be visible from the trains of the Pennsylvania Railroad as well as from the Lincoln Highway.

Regional Meeting at Niagara Falls May 26-28

A program of unusual interest has been arranged for the Regional Meeting which will be held at the Niagara Hotel, Niagara Falls, N. Y., May 26-28, under the direction of the Northeastern District of the Institute. The technical sessions will include a symposium on measurement of dielectric power factor, papers on transmission, tests of hydroelectric units, rectifiers, transformer design, polarization of radio waves, armature reactance, magnetic-flux measurements, current transformers, supervisory control, fire protection for generators, etc. A list of the technical papers was published in the JOURNAL for April 1926, page 391, and a complete program will be distributed by mail prior to the meeting.

One paper not included in previous announcements but to be presented at the meeting is that of T Spooner on "Current Transformers with Nickel-Iron Cores;" also there will be a short talk on *The Calibration of Lichtenberg Figures* by K. B. McEachron of the General Electric Company.

For this meeting, a number of delightful entertainment features have been arranged. There will be a boat trip on Lake Ontario, with dancing on boat; also a scenic and inspection trip through the Gorge, and a special illumination of the Falls, a convention dinner, and two attractive lectures.

Ladies are cordially invited and special arrangements have been made for their enjoyment.

The steamer trip on Lake Ontario will be made on Wednesday evening, May 26. The boat will be boarded at Lewiston and a delightful trip under a full moon is promised. Music will be furnished by a good orchestra and dancing may be enjoyed by all who desire it.

A trip to the Niagara Gorge will be made on Thursday afternoon when the marvelous rapids and whirlpool may be seen. Stops will be made at points of scenic interest and at the power plants on both sides of the ravine, and there will be guides ready to take groups through the plants.

On Thursday evening, the Convention dinner will be held in the Niagara Hotel and a number of Institute officers will speak briefly, including President M. I. Pupin, E. D. Adams, C. C. Chesney, Guiseppe Faccioli, H. M. Hobart and others.

Following the dinner a lecture, with interesting demonstrations on "Modern Reproduction of Sound," will be delivered by L. T. Robinson.

The special illumination of Niagara Falls, which is planned for Thursday night, will be a spectacle of great beauty. The Falls will be bathed in light of changing forms and colors.

A piano recital by Vladimir Karapetoff, together with an interesting interpretation of the music played, is planned for Friday evening as one of the enjoyable events of the meeting.

The first exhibition of the new film of the Niagara Falls Power Company will be given if possible Friday evening in connection with a lecture on the possible future power and scenic developments at the Falls, by George S. Anderson of the Niagara Falls Power Co.

Reduced Railroad Fares

Reduced railroad rates, under the certificate plan, have been granted and every visitor who comes to the meeting by train should get a certificate, if not for his own benefit at least to help others who will want to take advantage of the reduced fare.

Under this plan, every visitor should request a certificate from his local ticket agent when purchasing his ticket to Niagara Falls. If 250 certificates are turned in at the meeting, return tickets over the same route may be had at half-fare rates. There are certain restrictions regarding dates, extra-fare trains, etc.; this information should be obtained from local ticket agents.

Everyone who travels by rail to the meeting *should get a certificate*, whether or not he intends to use it, for as above stated by obtaining a certificate he will help make up the 250 which are necessary to make the reduced fare available to those who wish to take advantage of it.

The Niagara meeting has been planned by the Coordinating Committee of the Northeastern District consisting of H. B. Smith, Chairman, Vice-President in the Northeastern District; A. C. Stevens, Secretary; J. R. Craighead, E. D. Dickinson, J. A. Johnson, A. E. Soderholm and A. W. Underhill, Jr. Local arrangements are being made by a committee of which J. A. Johnson is Chairman.

Madison Regional Meeting May 6-7

Arrangements are completed for the Regional Meeting of the Great Lakes District, to be held in Madison, Wis., at the Hotel Loraine, May 6-7. The program contains technical papers on the subjects of rural electric service, high-voltage cables, interconnected systems, research between colleges and industries and radio receiving circuits. A convention dinner and inspection trips are also scheduled. A complete program was published in the April issue of the Institute's JOURNAL, page 390.

Student Convention at M. I. T. May 7

Plans are practically complete for the Student Convention of the First District of the Institute to be held at Massachusetts Institute of Technology, Cambridge, Mass., on May 7. The tentative program is as follows: In the morning, there will be three or four student papers and discussions. At noon there will

be a luncheon and Counsellor's meeting. In the afternoon inspection trips will be made to Edgar Station, Simplex Wire and Cable Company, a machine-switching telephone exchange and the M. I. T. Laboratories.

A joint banquet with the Boston Section will be held in the evening. Dr. M. I. Pupin, President of the A. I. E. E., will speak on "Science and Engineering." The other speaker of the evening will be Mr. R. E. Doherty, of the General Electric Company.

Stanley A. Tucker, Chairman of the Yale Branch, will preside at the morning session. Prof. H. B. Smith, Vice-President in the First District, will act as toastmaster at the banquet in the evening and is sponsoring the meeting of the Counsellors.

A student committee, of which Stuart John is Chairman, is arranging the meeting with the assistance of Vice-President H. B. Smith and J. W. Kidder, R. D. Booth, W. H. Colburn, H. W. Timbie and H. B. Dwight, all of the Boston Section.

Annual Convention, June 21-25 at White Sulphur Springs

The forty-second Annual Convention, which will be held at *The Greenbrier*, White Sulphur Springs, West Virginia, June 21-25, will be very interesting and enjoyable technically and socially.

In the technical program there will be papers on such subjects as magnetization, remotely-controlled substations, high-speed circuit breakers, electric transients, machine windings, regenerative braking, non-harmonic alternating currents, theory of synchronous machines, heat transfer in machines, etc.

The reports of Institute's Technical Committees will form a major part of the technical sessions. These should be of interest to all, as they are written to describe advances in design and practise in the various fields of electricity.

As a feature of general interest it is planned to have addresses by representatives of the American Engineering Council and the American Engineering Standards Committee. The objects and activities of these organizations will be explained, as well as their relation to the Institute and other electrical organizations.

White Sulphur Springs is an exceptionally attractive location for the Convention and *The Greenbrier* is a magnificent hotel, possessing every comfort and convenience. Among the attractions will be golf, tennis, horseback riding, motoring, sulphur baths, a swimming pool, not to mention the beautiful scenery of the place. All afternoons will be free for recreation.

A complete program will be published in the June issue of the Journal.

A. I. E. E. Directors' Meeting

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Friday, April 9, 1926.

Present: President M. I. Pupin, New York, Past-President Farley Osgood, New York, Vice-Presidents Harold B. Smith, Worcester, Mass.; A. G. Pierce, Cleveland; Managers H. M. Hobart, Schenectady, N. Y.; G. L. Knight, Brooklyn, N. Y.; W. K. Vanderpoel, New York; John B. Whitehead, Baltimore; E. B. Merriam, Schenectady, N. Y.; H. A. Kidder, New York; National Treasurer George A. Hamilton, Elizabeth, N. J.; National Secretary F. L. Hutchinson, New York.

The minutes of the Directors' meeting of February 9, were approved as previously circulated.

The Board ratified the action of the Executive Committee, under date of March 19, in approving applications for student enrolment, election to membership, and transfer from one grade to another.

Reports were presented of meetings of the Board of Examiners held March 8 and April 9, and actions taken at those meetings were approved. Upon the recommendation of the Board of Examiners, the following actions were taken on pending applications: 30 Students were ordered enrolled, 207 applicants were elected to the grade of Associate, 1 applicant was elected to the grade of Member, 1 applicant was elected to the grade of Fellow, 16 applicants were transferred to the grade of Member, 1 applicant was transferred to the grade of Fellow.

The Board ratified the approval by the Finance Committee for payment, of monthly bills amounting to $25,024.05.

Upon recommendation, approved by the Finance Committee, the Board voted to authorize the payment of traveling expenses, at the rate of ten cents per mile one way, of District Secretaries to the Section Delegates Conference at the Annual Convention, each year.

Upon request from the Pittsburgh Section, the Board authorized the extension of the territory of the Pittsburgh Section to include Marion and Harrison Counties, West Virginia.

The Board granted a request of the Portland, Seattle, and Spokane Sections for a readjustment of their boundaries to include territory not previously included in any Section.

Upon the approval of the Committee on Student Branches, the establishment of a Student Branch at Washington and Lee University, Lexington, Virginia, was authorized.

A proposed Uniform Electrical Ordinance and Uniform Statute, recommended by the Electrical Manufacturers Council, was considered and endorsed.

The Secretary announced the receipt of the trust fund for the Lamme Medal, bequeathed to the Institute by the late Benjamin G. Lamme, amounting to $5160 ($6000 less the inheritance tax); the formulation of a plan of procedure for making the award and the preparation of the design for the medal was referred to the Committee on Award of Institute Prizes for consideration and report to the Board of Directors.

The Board voted a gold medal award, in addition to the $100 previously authorized, in connection with the national "Best Paper Prize" recently established, to commence with the year 1926. The matter of design of this medal was referred to the Committee on Award of Institute Prizes.

In accordance with Section 33 of the constitution, the Board ratified the appointment by the President of the Tellers Committee, to report upon the ballots received in connection with the 1926 election of Institute officers, as follows: Messrs. S. P. Grace (Chairman), W. E. Coover, E. S. Holcombe, R. R. Kime, E. F. Thrall, E. F. Watson, and John T. Wells.

The Board confirmed the appointment by the President of Dr. Cary T. Hutchinson to succeed Dr. A. E. Kennelly as an Institute representative on the Engineering Division, National Research Council, and of Mr. Farley Osgood as an Institute representative on the Committee on Electric Power Houses, National Fire Protection Association.

Consideration was given to a request from American Engineering Council, and from the Denver Section of the Institute, that the Board of Directors go on record in approving Federal Bill H. R. 9397 to provide for inventory of water resources in the United States, and the Board voted its endorsement of the bill.

An invitation from the American Academy of Political and Social Science to be represented at the annual meeting, in Philadelphia, May 14-15, of that organization, was accepted, and the President was authorized to appoint delegates to this meeting.

The resignation of Mr. H. P. Gibbs as Local Honorary Secretary of the Institute for India, on account of leaving India, was presented, and upon the recommendation of Mr. Gibbs, Mr. F. W. Willis was appointed to succeed Mr. Gibbs as Local Honorary Secretary for India.

The Board accepted an invitation to appoint three representatives to attend the unveiling of the bust of Eli Whitney at the Hall of Fame, New York University, May 12, and Messrs. H. A. Kidder, G. L. Knight, and W. I. Slichter, were appointed.

Other matters of importance were discussed, reference to which may be found in this and future issues of the Journal.

First Plenary Meeting in United States of the International Electrotechnical Commission April, 13-22, 1926

The first plenary meeting of the International Electrotechnical Commission ever held in the United States opened April 13 and terminated April 22, in the Engineering Societies Building, New York.

More than one hundred delegates, representing most of the European nations and accompanied by about twenty ladies, arrived in New York about noon on April 13, on the Steamship *Andania*, and were met at the pier by a delegation of the official Reception Committee, including Messrs. John W. Lieb, Chairman, Frank W. Smith, C. E. Skinner, P. G. Agnew, F. R. Low, Elihu Thomson, C. O. Mailloux, Clayton H. Sharp, A. E. Kennelly, and C. A. Adams.

The first session, designed for the purpose of extending a welcome to the visitors, was held under the sponsorship of the United States National Committee in the Auditorium of the Engineering Societies Building, on Tuesday evening, April 13. Chairman John W. Lieb, of the Reception Committee, presided, and an address was made by Honorable Herbert Hoover by telephone from Washington, transmitted directly to the audience by amplifiers. Thomas A. Edison, Honorary President of the Reception Committee, sent greetings by telegraph from Florida, and a cablegram was read from the former Premier of Great Britain, Lord Balfour. Dr. Elihu Thomson, Past-President of the I. E. C., welcomed the delegates on behalf of the United States National Committee, and Dr. Howard T. Barnes, President of the Canadian National Committee, extended the greetings of the Dominion. Responses were made for Great Britain by Colonel R. E. Crompton, C. B., Honorary Secretary, I. E. C.; by M. E. Genissieu, of France; A. F. Enstrom, of Sweden; Professor V. List, of Czechoslovakia; Dr. P. Strecker, of Germany. The ceremonies were closed with the address by the President of the I. E. C., Guido Semenza, of Milan, Italy, on "Accomplishments and Aims of the International Electrotechnical Commission."

In a quotation from President Semenza's address, "when we unify nomenclature in electrical science and manufacture, and when we establish unified ratings for machines, then we shall have simplified production," the aims and activities of the I. E. C. are fittingly described. Out of the International Electrical Congress held in St. Louis in 1904 has grown this international standardizing body representing some twenty-four nations and to them has been due much of the international cooperation by which greater uniformity of practise, nomenclature and rating has facilitated international commerce. Through the medium of the U. S. National Committee standards in America have been communicated to the International body and the standardizing bodies here have been made fully acquainted with progress in the international field.

The Reception Committee tendered a luncheon to the visiting delegates at the Hotel Commodore on Wednesday at 12:30. Dr. John W. Lieb presided. Among the speakers were Dr. M. I. Pupin, President A. I. E. E.; Sir Archibald Denny, Dr. Guido Semenza, Dr. Clayton H. Sharp and Dr. C. O. Mailloux.

Numerous inspection trips to points of engineering interest, luncheons, and other events were carried out during the entire stay of the delegates in New York. For the ladies, a special program was arranged by the Entertainment and Hostesses Committees, including motor trips, theatre parties, teas, etc. On Thursday, April 15, a luncheon was tendered, to the chairman and secretaries of the various bodies engaged in standardization in the United States and abroad, by the American Engineering Standards Committee.

On Monday evening, April 19th, a banquet was tendered by the electric light and power companies of New York City to the visiting and American delegates and ladies, about three hundred in number, at the Hotel Astor. Mr. Gano Dunn, Past-President of the American Institute of Electrical Engineers and Chairman of the National Research Council, acted as toastmaster. The speakers were Hon. James J. Walker, Mayor, City of New York, John W. Lieb, Vice President, N. Y. Edison Company, Guido Semenza, President I. E. C., E. Uytborck, Chairman Belgian Delegation, C. Feldmann, President, Dutch Electrotechnical Committee, Domingo Santa Mario, Chili, E. Huber-stockar, Switzerland, and Sir Richard Glazebrook, Great Britain. Professor Lombardi extended an invitation to hold the next meeting in Italy.

On Wednesday evening, the 21st, with the visiting delegates of the I. E. C. as hosts, a banquet was given to the U. S. National Committee, also at Hotel Astor. President Guido Semenza presided. On behalf of the visitors he presented a beautiful statue of Nike, the winged Goddess of Victory. In response, Dr. Clayton H. Sharp, President of the U. S. National Committee thanked the delegates for the emblem of friendship and expressed the hope that this country would again have the privilege of entertaining the commission. Representatives of several of the nations represented expressed their felicitations.

INTERNATIONAL ELECTROCHEMICAL COMMISSION DELEGATES' VISIT TO THE WHITE HOUSE, WASHINGTON, D. C.

A complete list of the delegates from all countries follows:

LIST OF DELEGATES

Signor Guido Semenza, President, I. E. C.
Dr. C. O. Mailloux, E. E., Honorary President, I. E. C.
Col. R. E. Crompton, C. B., R. E., Honorary Secretary, I. E. C.
Mr. C. le Maistre, C. B. E., General Secretary, I. E. C.

Austria:
Herr Bretschneider, Vice-President, Austrian Standards Committee;

Belgium:
E. Uytborck, Secretary, Belgian Electrotechnical Committee;
L. Colson, General Director, Electrical Section, Belgian State Railways;
M. Danly, Société Financière de Transports et d'Entreprises industrielles;
Franz Dupont, Chief Engineer, Ateliers de Construction electrique, Charleroi;
C. Baron Forgeur, Director at Head Office, Ministry of Industry;
M. Victor Lagasse de Locht, Société Générale des Chemins de fer Economiques;

Canada:
James Kynoch, Chief Engineer, Canadian G. E. Co.;
John Murphy, Consulting Engineer, Dominion Government;
H. T. Barnes, President, Canadian National Committee;
I. L. Durley;

Czechoslovakia:
V. List, Chairman, Czechoslovakian Electrotechnical and Standards Committees;
F. Pergler, Czechoslovakian Standards Committee;
B. Rosenbaum, Secretary, Czechoslovakian Standards Committee;

Chili:
Domingo Santa Maria;

France:
G. J. Darrieus, Cie Electromécanique;
J. J. Frick, Société Alsacienne de Constructions Mécaniques;
E. Genissieu, Ing. en chef des Forces Hydraulics et de distribution d'energie au Ministére des Travaux Publics;
P. Girault, Cie. Fr. Thomson-Houston;
E. Roth, Société Alsacienne de Constructions Mécaniques;

Germany:
P. Strecker, President, German Electrotechnical Committee, Professor at Heidelberg;
P. Schirp, Secretary, German Electrotechnical Committee and V.D.E.;
L. Fleischmann, Allgemeine Elektricitas Gesellschaft;
Herr Hochtl, Chief Government Architect;
Dr. M. Kloss, Professor at Charlottenberg;
Oberingenieur A. Maier; German Standards Committee;
Dr. Moldenhauer, Markisches Elektrizitats-Werk;
Dr. Rudenberg, Siemens-Schuckertwerke;
Herr Schlothauer, Counsellor of Commerce;
Herr Schuchardt, Counsellor of Commerce;
Rich. Stern, Rhenania-Ossac Mineraloiwerke;
Herr Stotz, Engineer and Gen. Mgr., Stotz Company;
Director Strehlow;
K. W. Wagner, Office of Engineering Research, Administration of Posts and Telegraphs;
Dr. Kienzle, German Standards Committee;

Great Britain:
Sir Richard Glazebrook, K. C. B., Chairman, British National Committee;
Sir Archibald Denny, Bart., Chairman, British Engineering Standards Association;
L. B. Atkinson, Director, Cable Makers' Association;
C. P. Sparks, C. B. E., Vice-Chairman, British National Committee;
S. C. Bartholomew, General Post Office;
E. G. Batt, General Electric Co.;
W. S. Burge, English Electric Co.;
P. Dunsheath, W. T. Henley's Telegraph Works;
A. R. Everest, British Thomson-Houston Co.;
P. Good, Secretary of the British Delegation;
W. Lee, Silvertown Lubricants, Ltd.;
S. W. Melsom, Callender's Cable & Construction Co.;
A. C. Michie, Consulting Chemist;
R. B. Mitchell, Municipal Electrical Engineer, Glasgow;
A. P. Mossay, Messrs. Mossay & Company;
J. S. Peck, Metropolitan Vickers Electrical Co.;
C. Rodgers, O. B. E., Secretary, British Electrical & Allied Manufacturers' Association;
T. Roles, Municipal Electrical Engineer, Bradford;
P. F. Rowell, Secretary, Institution of Electrical Engineers;
F. Wallis, English Electric Co.;
K. Edgcumbe, Everitt Edgcumbe & Co.;
W. S. Marshall, Shell-Mex., Ltd.;

Holland:
C. Feldmann, President, Dutch Electrotechnical Committee and Professor at the Technical University, Delft;
W. H. Tromp, Secretary, Dutch Electrotechnical Committee;
C. Pot, Director of the Electrotechnical Works, formerly W. Smit & Co., Slikkerveer;
T. Rosskopf, Director of Transformer Works, Nijmegen;
C. Van der Bilt, Professor at the Technical University, Delft;
G. J. Van de Well, Extraordinary member of Patent Service;

Italy:
G. Semenza, President, I. E. C.;
L. Lombardi, President, Italian Electrotechnical Committee and Professor at Technical Engineering College—Rome;
G. Bianchi, Italian State Railways;
Carlo Clerici, Soc. Edison per la Fabbricazione delle lampade Ing. Clerici;
Piero Ferrerio, Società Générales Italiana Edison di Electricci;
Oreste Jacobini, Italian State Railways;
G. Minucciani, Italian State Railways;
E. Morelli, Professor of Electric Machinery Construction at the School of Engineering, Turin;
Ing. Luciano Pello;
Natale Ratti, Riva Company of Milan;
E. Theseider-Dupre, Italian State Railways;
Ingr. R. Vallauri, Professor of Electric Traction at the Milan Technical School;
E. Virgilli, Italian State Railways;

Norway:
E. Heiberg, Director, Norwegian Industrial Standardisation Bureau;

Poland:
C. Daewnowski, Secretary, Polish Electrotechnical Committee;
Mr. Roginski, Secretary, Polish Standards Committee;

Russia:
M. Chatelain, Chairman, Russian Electrotechnical Council, Vice-President, Russian Standards Committee;
Mr. Lapiroff-Scoblo, Russian Standards Committee;
Mr. Papernoff, Secretary, Russian Standards Committee;
Mr. Zischievsky, Russian Standards Committee;

Sweden:
S. Norberg, Vice-President Swedish Electrotechnical Committee and Swedish General Electric Co.;
A. F. Enstrom, President, Swedish Standards Committee;
Mr. Ericson, Secretary, Swedish Electrotechnical Committee;
Amos Kruse, Secretary, Swedish Standards Committee;
Mr. Nordstrom, Swedish Standards Committee;
H. Nystrom, Secretary, Electric Manufacturers Association;
Mr. Osterberg, Asst. Secretary, Swedish Standards Committee;
G. Thielers, Swedish General Electric Co.;

Switzerland:
E. Huber-Stockar, President, Swiss Electrotechnical Committee;
A. Huber-Ruf, Engineer, Brown Boverie Co.;
Charles Burlet, Electrical Engineer, Swiss Federal Railways;
C. Hoenig, Chairman, Swiss Standards Committee;
Hans Max Schindler, Ateliers de Construction, Oerlikon;
Antoine Schrafl, Swiss Federal Railways, (Construction and Working); Paul Thut, Bernese Power Works;

Spain:
Vicente L. Ramirez, Vice Consul in New York;

United States of America:
C. A. Bates, Electrical Engineer, Bryant Electric Company;
W. F. Durand, Professor of Mechanical Engineering, Stanford University;
A. E. Kennelly, Professor of Electrical Engineering, Harvard University;
F. R. Low, Editor, *Power*;
C. O. Mailloux, Consulting Engineer;
J. Franklin Meyer, Physicist, Bureau of Standards;
A. H. Moore, Electrical Engineer, General Electric Company;
R. W. Owens, Design Engineer, Westinghouse Electric & Mfg. Co.;
F. D. Newbury, Manager, Power Engineering Department, Westinghouse Electric & Mfg. Co.;
D. W. Roper, Supt. of Street Department, Commonwealth Edison Company;
C. E. Skinner, Assistant Director of Engineering, Research Department, Westinghouse Electric & Mfg. Co.;
E. A. Snyder, Chemist, General Electric Company;
N. W. Storer, General Engineer, Westinghouse Electric & Mfg. Co.;

Following the adjournment of the plenary session the delegates left on the official tour, to cover a period of twelve days, April 23 to May 5 inclusive. Transportation for the entire trip was furnished to all accredited foreign representatives and many sight-seeing trips, luncheons and dinners were arranged by local committees in the various cities. The cities visited were: Philadelphia, Washington, Pittsburgh, Chicago, Detroit, Niagara Falls, Ottawa, Montreal, Boston, and Schenectady.

Plenary and Technical Meetings

The technical work of the Commission is placed in the hands of advisory committees, of which there are now ten studying the following subjects:

- Nomenclature
- Rating of electrical machinery
- Symbols
- Prime movers, hydraulic and steam
- Resistance of aluminum
- Lamp caps and holders
- Voltages for distribution systems and test voltages for apparatus
- Traction motors
- Insulating oils
- Rules and regulations for transmission lines

Experience has shown the necessity for making it a rule that no decision of an advisory committee shall be submitted to the Plenary Meeting for ratification until the national committees have had an opportunity of instructing their delegates on the subject. Whilst this leads to an apparent delay, it can be asserted that in the long run it is really the quickest way, as it reduces to a minimum changes in the decisions reached.

At the New York meetings, a number of matters were ready for final decision, as the following reports will show:

Nomenclature. This committee is engaged on one of the most difficult, yet perhaps the most valuable of the tasks undertaken by the Commission. The value to the world of a unified technical language is not easily measured, and the production by the I. E. C. of an electrical vocabulary will provide that unity and stability to the language of the engineer, which is so essential to a clear understanding of the written word among all the nations.

The advisory committee consists of representatives from ten countries, but it has found it necessary to delegate the preliminary work to a subcommittee consisting of: Dr. C. O. Mailloux (U. S. A.), Professor Lombardi (Italy), Mr. Van der Well (Holland), Professor Janet (France), Mr. Wharton (England), Dr. Strecker (representing the Teutonic languages), and Professor Chatelain (representing the Slavonic languages). This subcommittee will submit to the different national committees a list of terms and will ask each of the national committees to study the definitions of these terms in the national vocabularies which have already been submitted, and to inform the subcommittee which definition they consider most suitable for adoption. With these replies before them, the subcommittee will submit to the full committee a recommendation in regard to the first list of definitions for adoption by the I. E. C. The British vocabulary has been accepted as the model for the arrangement and classification of the subject matter.

Note: Five countries have already sent in their national vocabularies in either English or French.

Rating of Electrical Machinery. This committee reached definite decisions in regard to the temperature rises of large machines, including steam turbine-driven alternators and alternators not steam turbine driven if of similar high speed construction. The following table shows the decisions:

TEMPERATURE RISES OF LARGE MACHINES
(INCLUDING TURBO-TYPE MACHINES)

TABLE I
LIMITS OF TEMPERATURE RISE OF ROTORS MEASURED BY RESISTANCE METHOD

	Class "A" Insulation	Class "B" Insulation
Rotors of steam driven alternators, and all other alternating current machines of similar high speed construction............	....	90 deg. cent.
Rotors of salient pole machines above 750 kv-a. and of which the stator cores exceed 50 cm. in 1 length axially................	60 deg. cent.	80 deg. cent.

TABLE II
LIMITS OF TEMPERATURE RISE OF STATORS MEASURED BY EMBEDDED TEMPERATURE DETECTOR METHOD

	Two, or more, coils per slot		One coil per slot	
	Class A	Class B	Class A	Class B
Steam driven turbine driven alternators and all other alternating current machines of similar high speed construction having an output of 5000 kv-a. or more.........	60	80	Detector, outside coil insulation 55*	70*
			Detector, inside coil insulation 65	85
All salient pole machines having either an output of 5000 kv-a. or more, or core length of one met. or more........................	60	80	Detector, outside coil insulation 55*	70*
			Detector, inside coil insulation 65	85

*For machine windings up to 7000 volts. For machine windings of more than 7000 volts the limiting temperature rise is reduced below the figures specified in the table one and a half degree centrigrade.

Decisions were reached in regard to the methods to be employed for temperature measurements when made by embedded temperature detectors.

The classification of insulating materials into Classes *O*, *A*, *B* and *C*, was definitely confirmed. The classifications agreed upon are practically identical with those which have prevailed for some time in this country, and therefore are not reproduced here.

It was decided to recommend to the national committees the following high-voltage tests on electrical machines:

HIGH-VOLTAGE TESTS

Rotating machines....	Test voltage (one minute)
10,000 kv-a. and up E up to 2000 volts....	$1000\ v + 2\ E$
E over 2000 volts to 6000 volts..........	$2.5\ E$
E over 6000 volts.....	$3000\ v + 2\ E$

I. E. C. Publication 34, Volume I. This I. E. C. publication contains the rules for machines up to 750 kw. size, and it has been decided to extend the scope of these rules and include the decisions reached in regard to large machines so as to make it applicable to all machines other than those for traction purposes.

Spark Gap Dimensions. The British Committee made a proposal that the I. E. C. should establish an international series of spark gap dimensions, and after some discussion, the American spark gap dimensions, which had come into almost universal use, were recommended for adoption.

Experts' Papers. Following the practise started at the Hague, President Semenza invited papers from different countries on subjects named by him, and the following papers were read:

Subject—In each country, what is the importance of the demand for an overload and what are the main reasons for such a demand?

Mr. F. Dupont, Belgium,
Mr. C. F. Hirshfeld, U. S. A.,
Mr. A. Huber-Ruf and Dr. Behn-Eschenburg, Switzerland,
Mr. C. Rodgers, O. B. E., Great Britain,
Mr. R. Liljeblad, Sweden,
Dr. M. Kloss, Germany.

Subject—The Ambient Temperature as a testing temperature of reference and as a climatic entity.
Mr. Roger T. Smith, Great Britain.

Subject—The true meaning of Ambient Temperature, limits of temperature and temperature rise.
Professor E. Morelli, Italy.

Subject—Is it possible to formulate general laws of equivalence between electrical machines having ratings with different temperature rises?
Mr. A. Huber-Ruf and Dr. Behn-Eschenburg, Switzerland.

Subject—Can the thermal capacity of electric machines be made a simple and practical element of Rating?
Dr. A. E. Kennelly, United States.

A general discussion on these papers took place, and at the conclusion, Professor Feldmann, Chairman of the Rating Committee, in his summary of the discussion made the following observations:

1. That there is no general demand for the inclusion of a sustained overload in the I. E. C. rating.
2. If conditions of service or industry make a second rating desirable, the I. E. C. rating should be stated on the nameplate.

Advisory Committee on Terminal Markings. This committee received a report of the small committee which had met in Paris, and invited the members of this committee, with one or two additions, to continue their study at this meeting. This committee is preparing a statement of the position in regard to terminal markings in the different countries for reference to the national committees.

Marking of Battery Terminals. It was found that with the exception of Czechoslovakia, all countries used red for the positive terminal, and blue for the negative terminal of batteries, and Professor List, representing the Czechoslovakian Committee, stated that he was authorized to say that if a decision was reached to adopt that coloring, his country would alter theirs to conform, although this meant reversing the colors now in use in that country. It was therefore unanimously agreed to recommend the adoption of red for the positive terminal and blue for the negative terminal.

There was some discussion as to whether this decision should not be qualified by recommending that brown be used in cases where red is being used as a danger signal, but it was definitely agreed that no confusion was likely to arise, and this proposal was not accepted.

VOLTAGES AT CONSUMERS' TERMINALS

Direct current	Alternating current	
	Single phase	3-Phase
		Between phase and neutral
1 x 110	1 x 110	110
2 x 110	2 x 110	127
4 x 110	1 x 220	220
1 x 220		
2 x 220		
1 x 440		
1 x 115	1 x 115	115
2 x 115	2 x 115	133
4 x 115	1 x 230	230
1 x 230		
2 x 230		
1 x 460		

One or other of these two series only being used in any country.
Note—In three-phase systems the resulting pressures between the phases corresponding to the standard pressures between phase and neutral given in the above table (column 3) may be considered as standard.

ALTERNATING CURRENT—3-PHASE

Nominal (Mean Value at consumers' terminals)	Maximum Voltages
1,000	1,100
3,000	3,300
6,000	6,600
10,000	11,000
15,000	16,500
20,000	22,000
30,000	33,000
45,000	50,000
60,000	66,000
80,000	88,000
100,000	110,000
150,000	165,000
200,000	220,000
300,000	330,000

Advisory Committee on Symbols. This committee successfully completed the work of preparing a comprehensive list of graphical symbols for heavy current engineering. The importance of the establishment of what is, in effect, a universal language for electrical diagrams hardly needs emphasis. This committee was, in addition, able to submit for definite adoption a list of graphical symbols for electric traction.

Symbol for Ohm. It was definitely decided to adopt Ω as the symbol for ohm.

Advisory Committee on Prime Movers. More sessions of the Advisory Committee on Prime Movers were held at the New York meeting of the International Electrotechnical Commission than at any of the previous meetings. At these sessions the committee discussed the important elements of test codes for water turbines and steam turbines. The five regular sessions were held on April 14, 15, 16, 19 and 20th and between these sessions two large sub-committees developed detailed reports on each of the test codes.

At the first session President Semenza introduced Dr. William F. Durand of Stanford University, California, and Past President of the American Society of Mechanical Engineers, as the Chairman of the Advisory Committee on Prime Movers for the New York meeting. The roll call of official delegates showed that the following countries had sent representatives: Canada, Czechoslovakia, France, Great Britain, Italy, Norway, Sweden, Switzerland, United States of America. Germany is a member of this Advisory Committee but was unable to send a delegate on this subject to the New York meeting. The United States was represented by Dr. Fred R. Low for Steam Turbines and Mr. H. Birchard Taylor for Water Turbines.

At the opening sessions devoted to Water and Steam Turbines, respectively, the Advisory Committee discussed more or less in detail the various proposals of the several national committees which had been presented at the Hague meeting or had been distributed by mail prior to the New York meeting. Topics of the proposals concerning which differences of opinion developed were referred to sub-committees for further study. The two sub-committees submitted full reports at the Tuesday evening meeting, April 20th, and abstracts of these reports were presented to the Plenary Meeting on the following day.

The report on Water Turbines presents thirteen different porposals which cover important decisions in matters of definition, tolerance or margins in guarantees, speed regulation, pressure variations, methods of test and measurement.

The report on the testing of Steam Turbines covers rating, speed regulation, information to be furnished with an enquiry or

order, interval between installation and test, tolerances or margins in guarantees, weighted average steam consumption and methods of making corrections to test data.

Advisory Committee on Lamp Caps and Lamp Holders. Agreement was reached in regard to the dimensions of Bayonet lamp caps and holders. The differences which have hitherto prevailed between the dimensions used in the two or three countries using this type of holder have been successfully eliminated. Agreement has not yet been reached in regard to the screw cap and holder, there being a difference in the depth of the thread between the continental and American standards, and a compromise, which will not put out of action the very large number of lamp holders in use all over the world, is being sought.

Advisory Committee on Voltages. The Plenary Meeting accepted the recommendation of this Advisory Committee that the following voltages should be used for new systems:

Definition of Nominal Pressure. The nominal high voltage shall be the mean voltage at the consumers' terminals and shall be called nominal I. E. C. Voltage of the network of that pressure range.

The maximum voltage at the generators and secondary terminals of transformers shall be considered to be about 10 per cent higher than the mean voltages at the consumers' terminals.

The maximum and minimum values of the voltages according to paragraph 1, and the variations occurring under working conditions will be considered at a later meeting.

Preferred Nominal High Voltages. The high voltages which are underlined in Tables I and II are recommended as the preferred high voltages.

This committee is now endeavoring to set up a series of voltage ranges for insulators for overhead line construction and switch gear.

Advisory Committee on Traction Motors. This committee recommended to the Plenary Meeting the adoption of a specification for traction motors, subject to the French Committee agreeing to one or two of the points which their delegate was unable to accept without reference back.

The following are the principal points:

Scope: The specification relates to all types of Traction Motors.

Classes of Rating: Two classes of rating are recognized:

(a) The I. E. C. continuous rating

(b) The I. E. C. one-hour rating

Overload Test: Sixty seconds with current equal to twice the one-hour rated current at rated voltage without mechanical injury or flashover or damage to commutation.

TEMPERATURE RISES

Continuous rating	Armature & Field Windings	Class A material	Resistance	85
			Thermometer	65
		Class B material	Resistance	105
			Thermometer	75
	Commutator & Collector	Class A and B	Thermometer	85
One hour rating	Armature & Field Windings	Class A material	Resistance	100
			Thermometer	75
		Class B material	Resistance	120
			Thermometer	97
	Commutator & collector	Class A and B	Thermometer	90

Service Conditions: The rating is based on the assumption that the air temperature will not exceed 25 deg. cent.

Advisory Committee on Insulating Oils. This committee in the course of its discussions made considerable progress and has recommended to the national committees the following recommendations:

(a) That the viscosity of transformer oil be expressed as kinematic viscosity using as a unit the kinematic centi-poise.

(b) That during the next year the viscosity of transformer oil shall be determined at 20 deg. cent. and 40 deg. cent. to the end that at a future meeting of the Advisory Committee a decision can be reached to adopt a single temperature.

(c) That in order to arrive at a practical short-time acceptance test, the research test has to be established first. After all practical and recognized forms of research test have been considered, then the question of the acceptance test to be adopted could be decided. At present only the research test is to be studied and the National Committees should retain their present acceptance tests.

(d) That in order to obtain data to furnish the basis of discussion at the next meeting of the Commission, the following four characteristic tests on transformer oil shall be made: Swedish, Swiss, German, U. S. A.

These tests to be carried out at the following two temperatures:

(a) At the standard temperature as prescribed by the National rules.

(b) At a temperature of 110 deg. cent.

Advisory Committee on Rules and Regulations for Overhead Transmission Lines. This committee has reviewed the rules and regulations for overhead transmission lines in the different countries and it has expressed the wish that those responsible for overhead line construction in the various countries should get into touch with the I. E. C. through their national committee, so that in future they can formulate their rules on the model already laid down. It has been decided that an attempt shall be made to keep the comparison of the rules of the different countries, which was prepared by the Belgian Committee, up to date and furnish each national committee with a copy of this every year.

The Belgian Committee has been nominated to act as Secretary for this work.

A. I. E. E. Annual Business Meeting New York, May 21, 1926

The annual business meeting of the A. I. E. E. will be held on Friday, May 21, at 8:15 P. M. (daylight saving time) in the Engineering Societies Building, 33 West 39th Street, New York City. At this meeting the reports of the Committee of Tellers on the annual election of Institute officers will be presented, as well as the report of the Board of Directors for the year ending April 30, 1926.

In connection with this meeting an interesting program will be offered by the New York Section. More complete information on this meeting will be mailed to the Section membership in advance of the meeting.

Carnegie Institute Special Summer Session

As a result of the demand that has been developing during the past few years, it is announced that this year courses in electricity are receiving special attention in the plans for the Summer Session at the Carnegie Institute of Technology in Pittsburgh. According to plans, the College of Industries will give six weeks' courses, from June 28 to August 6, in elementary electric wiring, advanced electric wiring, elementary principles of electricity, advanced electricity, and elementary principles of radio communication. It is reported that the radio course has been an outstanding success in the summer school work during the past three years.

In addition the College of Industries will give a course in Engineering Drawing and other arts.

Future Section Meetings

Baltimore

Inductive Interference, by H. S. Phelps. Engineers' Club. May 21, 8:15 P. M.

Cincinnati

Joint Meeting with Cincinnati Engineers' Club. Talk by Dean Schneider, University of Cincinnati. May 20.

Connecticut

Annual Meeting. New Haven. May 19.

St. Louis

Automatic Telephoning in St. Louis. May 19.
Annual Meeting. June 16.

Detroit-Ann Arbor

Standard Distribution Systems, by B. L. Huff, Commonwealth Power Corporation, and
A-C. Low-Voltage Networks, by H. P. Seelye, The Detroit Edison Co. May 18.

World Power Conference

According to announcement recently made by the State Department, the World Power Conference will be held at Basle, Switzerland, August 31st to September 12th, 1926; Mr. O. C. Merrill, Executive Secretary of the Federal Power Commission and member of the American Institute of Electrical Engineers has been appointed by President Coolidge as the United States delegate to this convention, the nomination having been made in response to an invitation received from the Swiss National Committee of the World Power Conference when the first world Power Commission met in London, 1924. This Commission was organized for the purpose of obtaining information and data concerning industrial and economic sources of power, both national and international. The meeting this year will be held simultaneously with the International Exhibition for Inland Navigation and is a special session called to discuss certain economic and financial features in the production of power.

Increase in Salaries of Federal Judges

The new Graham Bill in support of the increase of salaries for Federal Judges has been approved. It is believed that this will have a strong influence for good in maintaining the caliber of the courts, and their proceedings.

Museum of Peaceful Arts

A commission has been appointed to investigate the technique of museum development abroad in conjunction with the establishing here of a Museum of Peaceful Arts. These delegates will report back on their respective commissions; Mr. John W. Lieb has been appointed to report on light, fuel and power; Doctor Samuel W. Stratton, president of the Massachusetts Institute of Technology, on ship models, navigation and aeroplanes; Doctor H. Foster Bain, formerly Director of the United States Bureau of Mines and now Secretary to the American Institute of Mining Engineers, will attend the International Geological Congress to be held in Madrid in May, Doctor Louis Livingston Seaman will study medicine and hygiene and Doctor Ambrose Swasey, manufacturer and inventor, will report upon optics and physics. Elmer Ambrose Sperry, inventor and electrical engineer, sailed for Europe early in April, to study gyro-compass, aeroplane and ship stabilizers, high-power search lights and other devices in line with his special interests. Mr. Calvin W. Rice, Secretary of the American Society of Mechanical Engineers, and honorary secretary of the Museum, also sailed on April 10th. Other interests will be investigated and developed.

AMERICAN ENGINEERING COUNCIL

REPORTS ON COUNCIL WORK

At the recent meeting of the A. E. C. Administrative Board, Louisville, Ky., April 2nd, important matters upon which the Council has been working were reported as having shown encouraging progress. Progress Reports of the Department of Public Works and from the Committee on Street and Highway Safety were received. Of the seven continuing committees established by the Second National Street and Highway Conference, it was determined by the committee in charge that engineering representation should be had on at least five.

John Fritz Medal Presented to Edward Dean Adams

Edward Dean Adams was presented with the John Fritz Gold Medal on March 30 in the Engineering Societies Building, New York. Mr. Adams was chosen the medalist for the year 1926 for great achievement as an "engineer, financier, scientist, whose vision, courage and industry made possible at Niagara Falls the birth of hydroelectric power." The John Fritz Medal is awarded annually by representatives of the A. I. E. E., the A. S. M. E., the A. I. M. E. and the A. S. C. E. for notable scientific or industrial achievements. It was established in 1902 to perpetuate the memory of the achievements of John Fritz in industrial progress.

Dr. F. B. Jewett, Chairman of the Board of Award presided at the presentation and addresses were made by Hon. J. M. Beck, formerly Solicitor-General of the United States and Dr. A. E. Kennelly of Massachusetts Institute of Technology. Major F. J. Miller Chairman of the Board during 1925 presented the medal and Mr. Adams responded with a speech of acceptance.

Hon. J. M. Beck in commenting on the accomplishments of the medalist said in part:

It is a curious fact that our nation, so wonderfully rich in achievement, has been singularly slow and niggardly in the recognition of worth, outside the narrow sphere of political life, and very limited in that respect. This may arise from two divergent theories that have always marked the life of America: the one, the theory of the pioneers, the ideal of inequality, and the other, the political theory of America, the ideal of equality. The two ideals are not consistent, although each has persisted in the minds of America and each has sensibly influenced the other.

As to the theory of inequality, by which I mean the theory that in the inevitable competion of life, "the race is to the swift and the battle to the strong," and that the true glory of man is in superiority rather than in equality—this theory has been the driving force of the American people.

But over and against this dynamic purpose of the American people—each man to do the best for his own life and to rise above his fellows if he can—is the political philosophy that all men are created equal. Nowhere in the Constitution is any power given to the Federal Government to recognize achievement, with one exception, and that a very restricted one, found in our patent system.

With few exceptions, such as the Congressional Medal of Honor for distinguished service in the Army, our Government has from the beginning steadily discountenanced any official recognition of public service.

Because of this lack of fitting recognition of genius and ability by the State, the Engineering Societies are to be the more congratulated for having thus supplied the deficiency in their own field. I wish that every department of activity had a "John Fritz" medal that would mark great achievement in some line of work. There are certainly great advantages in the fact that a medal like the John Fritz Medal should come from those who are experts in the particular field of human activity in which the achievement has been made. And yet I venture to express the hope that some day our nation will create a great national commission which would once a year award a medal to some citizen who, either in that year or in his lifetime, had rendered some exceptional service to the State.

There is one other thought to which I want to give very inadequate expression, and that is the respect in which the award of this medal to Mr. Adams particularly appeals to me. Mr. Adams is of that class of men—a very rare class—who, by example and precept, go far to solve what is the great enigma of our time, the reconciliation of the ever-increasing growth of dynamic power with the growth of the spiritual power in human life. In other words, if there be one enigma which thoughtful men of all nations

are now considering more deeply than at any previous time in history, it is whether the high potential of dynamic power either raises or lowers the high potential of man's spiritual nature. In other words, whether the excessive mechanization of human life is not leading to certain evils that may well give concern to all who try, timidly at best, to scan the future.

It would be easy to demonstrate the enormous part that mechanical invention had played in the progress of mankind. But on the other hand, there are many wise and thoughtful men who perceive that an excessive mechanization of human society is bound to have baleful and portentous effects upon the human spirit. It is the greatest problem with which, in my judgment, humanity has to deal.

If there be any solution of this question, it lies, it seems to me, in a class of men, true leaders in human life, being developed, who are men of telescopic, rather than of microscopic brain.

With the mechanization of human society, human society becomes complex; and as it becomes complex, there is an unavoidable tendency to specialize; and as men become more specialized, of necessity there is a certain disintegration and a lack of solidarity of the social forces of human life. One remedy for that is to develop a class of leadership in the community of men of telescopic brains, who are not merely the devotees of any one branch of human activity, but whose minds are broad and have a natural taste and interest for everything that pertains to mankind.

That is the characteristic of Edward Dean Adams.

It is not only on the personal side of his character that I would prefer to dwell, but it is in respect to his versatility that I think this John Fritz Medal is so well and wisely bestowed. Indeed, all mankind has been his interest. In any department of activity, be it philanthropy, art, literature, music, engineering, industry or finance, wherever he has seen an opportunity for service, he has undertaken to render that service.

I do not know how I can better end these scattering and inadequate observations, or end my individual tribute to Mr. Adams than by quoting the words of no less a man than George Washington, applied to the first electrician of America and the first inventor of his age—Benjamin Franklin.

And so, interpreting the sentiments of all Mr. Adams' friends I venture to say, in the words of Washington: "If to be venerated for benevolence; if to be admired for talents; if to be esteemed for patriotism; if to be beloved for philanthropy can gratify the human mind, you must have the pleasant consolation to know that you have not lived in vain."

Dr. A. E. Kennelly in paying further tribute to Mr. Adams spoke in part as follows:

Looking back from 1926 to the year 1890, it seems now so easy to imagine how a power-transmission plant might then have been brought into existence, in view of the developments which have occurred since that period; but at that date, it was a matter of extraordinary difficulty. Competent scientists and engineers were at variance in their opinions, as to how power might be developed and transmitted from the Falls.

It is therefore all the more wonderful that, in the history we are considering this evening, the initial steps were taken upon a scale that was then gigantic. The Niagara plant is a monument to our medalist, in that the vast scheme he gradually developed, commencing in 1890, has known no retrogression or change of plan, upon any appreciable scale. The great hydro-electric transmission system, as he first visualized it, has come steadily into existence, step by step. It required great foresight, courage, patience and tenacity of purpose, to take the responsibility that rested on his shoulders, as the leader of a band of financiers, organisers and engineers, to initiate that great undertaking.

It may be claimed that Mr. Adams has transported part of the cataract from Niagara to a myriad homes and factories.

He has carried there the power of those falls and the gleam of their light. There is not a fan motor spinning in any of those homes, but follows imitatively and obediently from afar, the whirl of the great Niagara turbine wheels. There is not a light that shines electrically within those homes, but may be regarded as borrowing its gleam from the laughing waters of the intake canals, as they take their plunge over the wheel pits. Even the laughter-loving children who lay their weary little heads upon their pillows at night, take one more glance at the incandescent lamp, just before some loving hand turns it off, to catch, if possible, one more gleam from the cataract, to carry with them into dreamland.

Not only has the power of this nation and of the whole world been advanced in a material sense by this marvelous deed; not only has American life been made richer, more beautiful, more wonderful by this achievement; but we ourselves have received a certain apotheosis by this conquest of the Falls.

So long as human records persist, and so long as the human race is able to read them, Niagara will retain its place as one of the great glories of the world and inseparably associated with it will be the conquest of the Falls, by the harnessing of their waters. When the bridle was thrown over them, the reins lay in Mr. Adams' hands.

We are privileged to see the culmination of that great work recognized by this ceremony here tonight. All honor to the man and to the deed.

In his response in accepting the medal Mr. Adams told something of the history of the Niagara development. Among other things he said:

A consideration of the nebulous state of the art of hydro-electric development and electrical transmission of power at that time is necessary to a proper understanding and appreciation of the work begun at Niagara Falls in 1890-1891. Contemplation of the original project reveals also the remarkable foresight of the founders and of the International Niagara Commission formed for the purpose of reporting on the project. At that time multi-phase work was virtually unknown in this country and the only alternating current apparatus consisted of small single-phase belted machines never run in parallel and seldom driving motors. The size of the hydraulic and electric units adopted at Niagara Falls was far greater than anything ever attempted. The style was absolutely new.

The history of the enterprise is contemporaneous with that of the electrical industry. The Niagara River Hydraulic Tunnel, Power and Sewer Company was organized in 1886 to promote the development of Niagara River under the plans of Thomas Evershed. Its present name, The Niagara Falls Power Company, was adopted in 1889 at which time contracts were made with The Cataract Construction Company for all work contemplated including hydraulic, mechanical and electrical design as well as the management and operation of the completed project.

Although the financial set-up of the original Niagara Falls Power Company and the personnel of its directorate have been greatly overshadowed by the engineering achievement, this part of the company's activities is none the less historic. It marked the liberation of American industry from European financial dominance. Heretofore all projects of any magnitude in the United States were financed in Europe and the hydro-electric development at Niagara Falls was perhaps the first great enterprise in this country built with American capital.

And yet, while The Niagara Falls Power Company sought no funds in Europe, it did seek there engineering aid and advice, for the reputation of the Swiss, Italians and French in hydraulics was well established, and England excelled in mechanics.

It was evident that the services of only the most experienced should be enlisted for guidance in such an enterprise and that commitment to the project should await consultation with those specializing in the general branches of the science involved.

Investigations in Europe led to the formation of a group of international scientists who undertook the joint consideration of engineering projects under the title of The International Commission, with headquarters in London. The records of that Commission form an important chapter in the history of the several sciences and particularly that of electricity inasmuch as the formation of that commission marked probably the first of the notable international conferences of scientists for industrial purposes. Lord Kelvin, then Sir William Thomson, presided as Chairman.

The decisions to abandon the old method of water-power development by a mill over a wheelpit and to adopt a central station for the development of water power and its distribution by compressed air, electricity or water under pressure were announced December 14, 1891. The official decision to adopt the alternating current was announced May 6, 1893, and the first contract for electrical generators was executed in October, 1893, for three alternators of 5000 horse power each.

The decision to adopt electricity, and particularly alternating current electricity, was not accepted without protest.

The controversy between the proponents of direct current and alternating current raged furiously in the early '90s. Thomas A. Edison, the electrical wizard, was the staunch and uncompromising advocate of direct current in the United States, and in Europe, Sir William Thomson, afterwards Lord Kelvin, the most famous physicist of his day, also espoused the cause of direct current. Westinghouse and Stanley in this country, and Ferranti, Brown, Mascart and Turrettini and others in Europe, championed alternating current.

However, it is obvious that the electric light and power industry would scarcely have made the remarkable advances it has were it not for the adoption of the alternating current in the initiation and propagation of which The Niagara Falls Power Company has borne a prominent and historic part.

Thus the influence of Niagara has spread broadcast over the earth, as though it were foredestined to inaugurate new impulses towards the development of world progress through the peaceful arts. Niagara has stimulated and focussed attention on water-power development, on electric transmission and on the utilization of electricity in the electro-chemical, electro-metallurgical and kindred arts. It is symbolic of engineering courage, daring and achievement, and prophetic of the fact that man is continually adapting and applying the natural resources and his genius toward the advancement and glory of civilization.

Prior to the presentation exercises a dinner was given to Mr. Adams in the Engineers' Club at which short addresses were made by W. H. Onken, Jr., editor of the *Electrical World*; L. B. Stillwell, chairman of the Engineering Foundation, and Prof. C. F. Scott of Yale University.

A large number of messages of congratulation were received from well known scientists, engineers, financiers, public officials and others.

Research Graduate Fellowships at University of Wisconsin

COLLEGE OF MECHANICS AND ENGINEERING

For the purpose of promoting engineering research and the development of qualified research men, the University of Wisconsin has established three research fellowships in the College of Engineering. These fellowships are granted under the following conditions:

Each fellow will be appointed for a period of two years, subject to satisfactory service. The salary will be $900.00 for the first year and $1100.00 for the second year. The fellow will be required to devote not less than half his time to assigned research work in the College of Engineering, but will, in any case, be given opportunity to complete his work for the M. S. degree within the two-year period. Candidates must be graduates of engineering colleges of recognized standing, and preferably should have had one or two years' graduate study or teaching or engineering experience. The period of service required will be the usual academic year, including the short vacations. The College of Engineering possesses well-equipped laboratories in which a considerable amount of research work is always under way. Results are published, from time to time, in bulletins of the Engineering Experiment Station. A total of sixty-three bulletins have been published up to the present time.

Applications for these fellowships for the year 1926-27 are now invited. For further information and application blanks, address F. E. Turneaure, Dean, College of Mechanics and Engineering, Madison, Wisconsin.

First Part of New Electrical Safety Code Now Ready

Rules for the installation and maintenance of electrical equipment in generating stations and substations are given in a new publication of the Bureau of Standards of the Commerce Department. These rules cover the general protective features of the station, as well as specific sections dealing with grounding, rotating equipment, storage batteries, transformers, conductors, fuses, switches, switchboards, and lightning arresters.

The first part of the code is known as Handbook 6 of the Bureau of Standards. Copies may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 10 cents each.

Special Exhibit of the American Electric Railway Association

During the period of October 4th to 8th inclusive, the American Electric Railway Association will hold its 45th Annual Convention at Cleveland, Ohio, with a special Manufacturers' Exhibit, to which both floors of the large Cleveland Public Auditorium will be given over. October 6th has been set aside as a day devoted entirely to demonstration of the exhibit and no technical sessions of any kind will divert attention from it on that day,—a day of inspection only.

Muscle Shoals Bids

The Special Joint Congressional Committee appointed to negotiate a lease of the Government Muscle Shoals property has received seven bids for leasing the entire project and two bids for leasing Plant No. 1.

These bids were opened April 10th by Representative James, of Michigan, Acting Chairman of the Committee, and momentary announcement is expected as to recommendations for the acceptable bid.

New York Section Holds Student Convention

On Friday, April 23rd, the New York Section held its first Student Convention. The convention was held in conjunction with a regular monthly Section meeting. All the details of the part taken by the students representing the eight colleges in the New York District were worked entirely by a Student Convention Committee, the New York Section officers and faculty representatives acting merely in an advisory capacity.

The convention proved a great success as instanced by the number and enthusiasm of the students participating and the quality of the student papers and discussion. Friday morning was devoted to inspection trips to the General Electric Lamp Works, the I. R. T. repair shops and the Bell Telephone Laboratories. The afternoon session held in the Engineering Societies Bldg., was opened at 2.30 by Student Chairman, J. C. Arnell, who promptly called upon Past-President Farley Osgood. Mr. Osgood gave an address devoted largely to advice to student prospective engineers, on the type of education likely to produce best results. Mr. Osgood's talk was very enthusiastically received. Eight students then presented papers as follows: "Recent Developments in the Manufacture of Vacuum Tubes," by D. Y. Smith, Cooper Union; "Field Measurements in Radio," by Mr. Remy, Columbia; "Measurements of High-Frequency Oscillations," by Lloyd Goldsmith, Brooklyn Polytechnic; "Engineering Applications of the Gyroscope," by Lincoln Walsh Stevens; "Automatic Telephony," Mr. Schneerveis, City College; "Cooperative Education from the Student's View Point," E. C. Fischer, Newark College of Engineering; "The New Cooperative System at N. Y. U." Theodore Smith, New York University. These papers were actively discussed. A committee appointed by the New York Section then judged the papers and a prize of $25.00 in gold was awarded Mr. Goldsmith, of Brooklyn Polytechnic, for the best presentation.

Following the afternoon session, the students and Section members, about 200 in all, had supper at the Fraternity Club. The New York Section held a regular meeting at 8.15 p.m. in the Auditorium of the Engineering Bldg. Chairman Kidder, presiding, announced the results of the election of Section officers for 1926-27, as follows: Chairman, E. B. Meyer, Public Service Electric Co. of N. J.; Secretary-Treasurer, O. B. Blackwell, A. T & T. Co.; Executive Committee, J. B. Bassett, General Electric Co.; and C. R. Jones, Westinghouse Elec. & Mfg. Co. A paper on "Refrigeration-Theory, History and Recent Developments" was then presented by A. R. Stevenson, Research Engineer, General Electric Co.

Philadelphia's Sesqui-Centennial

Any Institute member who may visit Philadelphia during the Sesqui-Centennial Year, 1926, will be extended the privileges of the Engineers Club of Philadelphia for a period of ten days, provided he brings a letter of introduction from an officer of the Institute.

Another announcement of interest to Institute members in connection with the Sesqui-Centennial is that a number of meetings will be held in Philadelphia during September by the Congress of American Industry.

ENGINEERING FOUNDATION

ARCH DAM INVESTIGATION

The work of the test investigations on the so-called "Stevenson Creek Test Dam," situated on a tributary of the San Joaquin River, 60 miles east of Fresno, Calif., is progressing. Since the December bulletin, the excavation in the granite for the dam foundation has been completed, the remainder of the instruments and accessories for the test obtained, the installation of the

construction plant finished, the test party camp established in camp and methods and programs for the test determined so far as possible in advance of actually putting them into practise. While the concrete is being placed, many instruments will be inbedded and preliminary observations taken. Other tests on concrete materials, concrete instruments and methods have been progressing. As previously stated, the Committee in charge will welcome any information which may be used in the study and preparation of the report, constructive criticism of its program and methods and general discussion of the design of arch or multiple-arch dams. Such correspondence should be addressed to the secretary, F. A. Noetzli, 928 Central Building, Los Angeles, California.

Westinghouse Annual War Memorial Scholarships

The Educational Department of the Westinghouse Electric and Manufacturing Company has just announced the plans for awarding the 1926 War Memorial Scholarships. These awards are made annually, the successful candidate receiving $500 during each year of his collegiate training, or a maximum of $2000.

Applicants eligible to compete for these Scholarships include sons of employees who have been with the Company five years, or more, and employees who have been continuously in the service for at least two years and who shall not, on September 1, have exceeded the age of 23.

Chandler Gold Medal Award

Award of the Chandler Gold Medal was made by Columbia University to Samuel Wilson Parr, professor of applied chemistry, University of Illinois. Professor Parr delivered his lecture at Havemeyer Hall, Columbia University, Friday evening, April 23d. Friends of the late Professor Charles Frederic Chandler, pioneer in the chemistry of this country and founder of the American Chemical Society, presented to the trustees of Columbia in 1910 a sum of money constituting the Charles Frederick Chandler Foundation; it is the income from this fund which is used to provide a lecture by some eminent chemist and the gold medal to be presented to the lecturer in further recognition of his achievements in science.

PERSONAL MENTION

W. J. Swales, after twelve years of service in Latin America and Cuba and of late Superintendent of the Cia Electrica De A. Y. T. de Santiago de Cuba, has resigned his position to return to his home in Canada, where he will enjoy a well earned vacation of three or four months with relatives and friends.

P. M. Rainey, who joined the Western Electric Company immediately after his graduation from college, has been appointed Telephone Sales Manager of the Graybar Electric Company, successor to the Western Electric Supply Department. This new incorporation took place the first of the present year.

Charles Byron Isaacson, formerly of the All Amenia Cables, Inc., is now associated with the Allied Engineering Company, New York City, as director and officer in charge of commercial development.

William A. Moore has accepted a position with the New York Edison Company, as Engineer of Purchases. For the past eight years Mr. Moore was with Hugh L. Thompson, consulting engineer, Waterbury, Conn. He was also chairman of the A. I. E. E. Connecticut section for the year 1924-25.

William B. Herbst, who was for eighteen years affiliated with the Duquesne Light Company, has resigned to become assistant electrical engineer for The Department of City Transit, Philadelphia, Pa.

H. M. Friend has just returned to the Brooklyn Edison Company after a thirteen months' leave of absence spent with Hugh L. Cooper & Company, consulting engineers on the Muscle Shoals Development. Mr. Friend attended to the inspection of all wire, cable and insulators for the Wilson Dam Power House, supervising and testing the installations.

Harrison D. Panton, who, for the past three years has been the principal of Harrison B. Panton & Company, Raleigh, N. C., has joined the organization of Francis R. Weller, consulting engineer, Washington D. C. Mr. Panton's new work will take him to Ocala, Florida, where he will be chief engineer in charge of all Florida-Georgia operations of the Weller organization.

E. O. Shreve, manager of the San Francisco office of the General Electric Company since 1918, has been named manager of the industrial department of the company with headquarters at Schenectady, filling the vacancy caused by the recent death of A. R. Bush.

J. W. Alvord to Receive Washington Award

John Watson Alvord, consulting engineer, has been selected to receive the Washington Award for 1926. The award will be presented at the Annual Meeting of the Western Society of Engineers on June 2.

The award is made annually by a committee of representatives from the Western Society of Engineers and the A. S. C. E., the A. I. M. E., the A. S. M. E. and the A. I. E. E. It was established in 1917 "to be presented annually to an engineer whose work in some special instance or whose services in general have been noteworthy for their merit in promoting the public good."

Obituary

James Winthrop Thomas, Fellow of the Institute and brother of Percy H. Thomas, died at his home, Plandome, L. I., April 13, 1926, in the 52nd year of his age.

Born at Boston, November 13, 1874, Mr. Thomas attended Exeter Academy, from which he entered the Massachusetts Institute of Technology, graduating in 1895 with a Mechanical Engineering degree. After serving a short apprenticeship with the Boston and Maine Railway Company in their shops at Cambridge, he went with the Wyoming Shovel Works, Wyoming, Pa., where he became assistant superintendent; thence he went to the Westinghouse Church Kerr & Company, for whom he was in charge of important installations including Westinghouse Lamp Works at Watsesing, N. Y. and Westinghouse stoker works at Attica, Nassau Hotel, Long Beach, L. I., N. Y. He then became engineer of the New England Engineering Company for a short period, leaving them to join the United Gas and Electric Company of Connecticut, where for many years he handled a great variety of work for their various properties.

Mr. Thomas was a member of The American Society of Mechanical Engineers, Fellow of the Institute of Electrical Engineers since 1920, a member of the Technology Club of New York and of the Phi Beta Epsilon Fraternity.

Herbert Wallace Cheney, who, for the past twenty years has been connected with the electrical engineering department of the Allis-Chalmers Manufacturing Company, died at his home in Milwaukee March 22d, 1926, after an illness of two months.

Mr. Cheney was born at Coldwater Lake, Michigan, February 7, 1872. Here he received his primary education through the small country school later attending the Valpariso University. After graduating from the university, he returned to Coldwater to teach and later entered the University of Michigan for the purpose of completing his engineering studies.

Following his university course, he was, for a short time, with Frank M. Dunlap, Consulting Engineer, Detroit, Michigan, spending also a few months with Charles A. Strelinger Co., Detroit, Michigan, as designer of machine tools. In January

1893 he entered the employ of the Leland & Falconer Manufacturing Company of Detroit who later became the Cadillac Motor Car Company. Six years later, Mr. Cheney went with the Westinghouse Electric & Mfg. Co., In 1904, when the Allis-Chalmers Company took over the Bullock Electric Manufacturing Company, Mr. Cheney joined the engineering department of the Bullock Plant, Cincinnati, as engineer in the design of detail electrical apparatus. In 1908 the engineering work was consolidated at the West Allis Works and Mr. Cheney moved to Milwaukee his work being particularly in connection with detail apparatus, airbrake equipment, small motor-driven air compressors, motor starters, etc.; he was also in executive charge of the experimental department for them. When Allis-Chalmers were making arrangement with A. Reyrolle & Company for the building of armorclad switchgear in this country, Mr. Cheney was sent to England with other engineers, to investigate the design of this new switchgear. To this work he was devoting his attention at the time of his death. Mr. Cheney was a Fellow of the Institute; he also served the Milwaukee Section as its chairman and on its program and membership committees. He was a member of the American Society of Mechanical Engineers, the Milwaukee Engineers' Society with which organization, during the past year, he was chairman of a committee on Education and Graduate Training. He was of a nature which endeared him to a large circle of friends while his earnest interest in all undertakings caused him to be held in high esteem by his associates.

William F. Meschenmoser, Vice-President of the Russell & Stott Company, New York City, died on March 16th, 1926. Mr. Meschenmoser was born in Brooklyn, December 4th, 1876. His fundamental education in mathematics, physics, chemistry, electrical and mechanical engineering was practically self acquired. He studied train control systems for two years, designing and drafting, one year; design and shop, electrical and mechanical for four years; was machine shop superintendent for five years and machinist and apprentice for four years. From 1894 to 1899, he was superintendent of design and building small special machinery for the Excelsior Co. He then identified himself with the F. W. Mills Company as superintendent of automatic electrical and mechanical machinery. From 1903 to 1904 he was working for himself at general electrical and mechanical machine design and construction supervision, but in 1904 joined the Kinsman Company, with whom he was engineer with general supervision of drawing room and field. For a number of years, Mr. Meschenmoser was active on the Committee of Application to Marine Works, beside rendering valuable service to the Institute and the profession in many other ways.

Charles G. M. Thomas, Associate of the Institute and Vice-President of the Consolidated Gas Company of New York died at his home, Flushing, L. I., March 23, 1926. Mr. Thomas was born July 2, 1866, in New York City and was educated in the city schools and the College of the City of New York. In 1888 he joined the Standard Gas Light Company of the City of New York and remained with them until 1901 in varying capacities, Cashier until 1893 and manager until 1901. He was then made vice-president and general manager of the Newtown & Flushing Gas Company, the New York and Queens Gas Company, the Williamsport (Pa.) Gas Company and the Dallas, (Texas) Gas Company, operating from New York City. In this office he remained until 1907, when he concentrated as vice-president and general manager of the New York & Queens Electric Light and Power Company, of which he was also chairman of the Board of Directors at the time of his death. Mr. Thomas' popularity and success in his undertaking may be emphasized, perhaps, by the fact that over 500 people were present at the services held for him at the Dutch Reform Church, Flushing.

Gordon Oke Philp, who, since 1919, has been superintendent of the Hydro-Electric Power Commission of Ontario, died at Niagara Falls, of blood poisoning contracted several months ago. Mr. Philp his associates felt, was destined for a most brilliant future and the Commission acknowledges the loss of a most capable executive. Born at Port Hope, August 17, 1892, he was educated through the public and high schools there. He decided to become an engineer and as soon as possible entered the University of Toronto, graduating from there with his degree of Bachelor of Applied Science in 1914. Vacation periods were spent with the Midland Construction Company in Central Ontario. After graduation he entered the engineering department of the Electric Power Company and when this company was taken over by the Ontario Government in 1916, he joined the operating staff of the Hydro-Electric Power Company. When the Commission acquired control of the Ontario Power Company, Mr. Philp was chosen as the man to assume the position of general superintendent, work required considerable skill and tact. During the last few years, added responsibility has been given him until, at the time of his death, he was satisfactorily holding the position of general superintendent of all operations and maintenance of the Commission's three properties; Queenston Development Company, the Ontario Power Company and the Toronto Power Company. Mr. Gaby, chief engineer of the Hydro-Electric Power Company, pays Mr. Philp the following tribute: "He has achieved success—who looked for the best there was in others and gave the best he had. Whose life was an inspiration and whose memory is a benediction." Mr. Philp joined the Institute in 1919 as an associate but advance to the grade of Member in 1925.

Willard G. Carlton, Superintendent of Power of the New York Central Lines and Fellow of the Institute, died at his home in Yonkers, New York, April 15th, of pneumonia.

Mr. Carlton was born in Warren, Illinois, February 20th, 1869. He was educated in the grammar and high schools of that town prior to his attending Cornell University, from which he graduated in the class of 1892. For one year immediately after his graduation, he was with the General Electric Company at Lynn, Massachusetts, taking their students' course, which he completed in 1893 and joined the Chicago Edison Company, with whom he remained in varying capacities until 1905. He left them to become Superintendent of Power for the Electric Division of the New York Central and Hudson River Railroad, in charge of distribution of power for the operation of electric trains in and near New York City. Mr. Carlton has been described as "an engineer of unusual originality, resourcefulness and force, with a prominent part to play in shaping the development of engineering." As chief operating engineer for the Chicago Edison and Commonwealth Electric Company, he had charge of all underground and overhead distribution systems and substations as well as all direction of extensions of distribution systems for the company. There is little doubt that Mr. Carlton leaves behind him much of future achievement in the profession as well as a host of friends. He served the Institute as a member of the Board of Directors 1908-11 and as Vice-President during the years 1911-13, beside being extremely active in its Committee work. He was a member of the Engineers Club, the New York Engineering Society, The American Society of Mechanical Engineers, the National District Heating Association, the Cornell Club of New York and the New York Railroad Club, all of whom were cognizant of the profitable and pleasant relationship.

Chester W. Lyman, director and vice-president of the International Paper Company until his resignation about a year ago, died at the Massachusetts General Hospital, April 15th. Mr. Lyman was born in New Haven 64 years ago, the son of Chester Smith Lyman, for many years professor in the Sheffield Scientific School, Yale University. Mr. Lyman attended the Hopkins Grammar School of New Haven and recently helped to raise funds for its reorganization and development. He graduated from Yale in 1882, and after a period of service with the United States Coast Survey, in 1885 identified himself with H. Parsons

& Company, starting his career as a paper manufacturer. In 1890, he joined the Herkimer Paper Company, Herkimer, N. Y., becoming its manager and director. Upon the absorption of this company by the International Paper Company, he continued his interest with them as assistant to the president until he was made vice-president in 1916. In 1895 one year after joining the Institute he was awarded the degree of M. A. for special studies in electrical engineering.

Mr. Lyman has contributed many articles to the trade journals and was an active member of the American Paper and Pulp Association. He also belonged to the American Forestry Association Sons of the American Revolution; and the University, Yale, Piping Rock and Midday Clubs.

Louis Anthyme Herdt. Macdonald Professor of Electrical Engineering, McGill University and vice-president of the Montreal Tramways Commission, died suddenly at his office, McGill Engineering Building, April 11, 1926.

Born at Trouville, France, June 14, 1872, Professor Herdt, while still quite young, came to Canada with his family; his early education was in the Montreal High School, he thereafter entering McGill University to graduate with honors from the Mechanical Engineering course in 1892. During his three years' study at McGill, five months out of each year he was working as assistant engineer for the Laurie Engine Company of Montreal. In 1893, he took a course in electrical engineering at the Institut Electrotechnique Montefiori, Liege, Belgium, graduating with a diploma of electrical engineering. From May 1894 to September 1895, Professor Herdt was assistant electrical engineer to the Thomson Houston International Company, Paris, whence he returned to McGill University, as demonstrator of electrical engineering, becoming consecutively lecturer, assistant professor, associate professor, and, ultimately, head of the department. Doctor Herdt was president of the Electrical Service Commission of Montreal, a member of the Engineering Institute of Canada, and Fellow of the American Institute of Electrical Engineers. In 1907 he was appointed delegate to the International Electrotechnical Commission, meeting then in London, England, and it was with deep sympathy and regret that the Commission, meeting in this country for the first time this year, heard of his untimely death. He was appointed Officer d'Academie de France in 1905 and Chevalier de Legion d'Honeur in 1923. Doctor Herdt was the author of several technical papers and contributed materially to the work of profession, both through the technical press and the engineering bodies with which he was identified. Beside his membership in the Engineering Institute of Canada, Doctor Herdt belonged to the Montreal Engineering Club.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES (MARCH 1-31, 1926)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

DIE ANWENDBARKEIT DER GEOPHYSIKALISCHEN LAGERSTATTENUNTERSUCHUNGSVERFAHREN, INSBESONDERE DER ELEKTRISCHEN UND MAGNETISCHEN METHODEN.

By Rudolf Krahmann. Halle (Saale), Wilhelm Knapp, 1926. 40 pp., 10 x 7 in., paper. 2,50 gm.

With the object of supplying the mining interests with a comprehensive, understandable presentation of the fundamental principles of the practical use of geophysics in the study of ore deposits, the author has prepared this brief survey of the practical geophysical methods for the exploration of ore deposits. The various methods, using the measurement of electromagnetic conductivity, specific potential, magnetic intensity, gravity, elastic waves, earth temperatures and radioactivity are described, and their possibilities pointed out. A bibliography is included.

BEITRAG ZU DEN GRUNDLAGEN DER SCHNELLAUFENDEN HALBDIESELMOTOREN.

By Karl Büchner. Halle (Saale), Wilhelm Knapp, 1926. 48 pp., illus., 11 x 7 in., paper. 3,50 mk.

A lecture upon certain directions in which there is a tendency toward technical advance in the utilization of heavy oil. The author calls attention to the possibilities of solid-injection for high-speed automobile engines as well as for stationary and marine Diesel engines. He next speaks of recent satisfactory adaptations of hot-bulb engines to automobiles, in controversion of the usual idea that this type is an antiquated step in the evolution of the engine. Finally, he suggests the desirability of more thorough investigation of the reactions underlying the formation of mixtures which ignite easily and burn rapidly. He devotes special attention to this third point.

DIE BEWEGLICHKEIT BINDIGER UND NICHT BINDIGER MATERIALIEN.

By V. Pollack. Halle (Saale), Wilhelm Knapp, 1925. 139 pp., 10 x 7 in., paper. 9,80 g. m.

Professor Pollack's monograph which brings together our knowledge of the mobility of cohesive and non-cohesive materials, treats a matter of great importance to geologists and civil engineers. The behavior of loam, clay, colloidal mud, sand, etc., under varying conditions of pressure and moisture is described and information given on their plasticity, cohesion, consistency and similar properties.

DYNAMICAL THEORY OF SOUND.

By Horace Lamb. 2nd edition. Lond., Edward Arnold & Co., 1925. 307 pp., 9 x 6 in., cloth. $6.00. (Gift through Longmans, Green & Co.)

Although a treatise on thi. subject is of necessity to a great extent mathematical, the author has tried to restrict himself to the simplest and most direct methods and processes possible, in view of the questions treated. In this sense the book is elementary and will, the author hopes, serve as a stepping stone to the writings of Helmholtz and Rayleigh.

This edition has been corrected and revised.

ECONOMICS OF THE RADIO INDUSTRY.

By Hiram L. Jome. Chicago, A. W. Shaw Co., 1925. 332 pp., diagrs., tables, 8 x 6 in., fabrikoid. $5.00.

A discussion of the economic and legal problems caused by the development of wireless communication. Taking the point of view that the function of radio is to render a more or less distinctive service of communication, the author analyzes its service problems as they affect society. He first discusses the development and extent of the industry, then most effective ways for making this service available to the people. The problems confronting the organizations rendering the service are then considered, while the final section of the book discusses the future of radio service and its relation to other social agencies and means of communication.

DIE ELEKTRISCHE TELEGRAPHIE MIT DRAHTLEITUNG, vol 1; Die Telegraphie mit Morsezeichen.

By J. Herrmann. Berlin u. Leipzig, Walter de Gruyter & Co., 1926. 134 pp., illus., 6 x 4 in., cloth. 1,50 mk.

The first volume of a brief practical textbook on telegraphy. This book is confined to telegraphy with Morse signals, the subject of printing telegraphs being left for a second volume.

The book opens with a brief review of the elements. The various circuits are then discussed, after which the author proceeds to cable telegraphy and high-speed systems. An excellent brief survey of the subject.

ENGINES OF HIGH OUTPUT; Thermodynamic Considerations.

By Harry R. Ricardo. Lond., Macdonald & Evans, 1926. (Reconstructive technical series.) 110 pp., graphs, tables, 9 x 6 in., cloth. 7/6.

Some years ago Mr. Ricardo published a series of articles giving a brief general analysis of the possibilities and limitations of high-speed gasoline engines. The present book is the first volume of a revision and amplification of that analysis. It deals particularly with the thermodynamic aspects of the problem. The author inquires into the factors that determine the efficiency of gasoline engines and discusses their application to practical design.

ENGLISH BRASS AND COPPER INDUSTRIES TO 1800.

By Henry Hamilton. N. Y., Longmans, Green & Co., 1926. 388 pp., illus., 9 x 6 in., cloth. $6.00.

Dr. Hamilton traces the development of these industries from their beginnings in the sixteenth century down to the year 1800, when they were firmly established in Birmingham, the city in which they are concentrated today. He is particularly interested in industrial organization, hence, it is the industrial and commercial organization of these industries which he studies rather than the evolution of manufacturing processes. The result is an interesting work which throws new light on industrial development during its period, of interest to students of economics, as well as students of the particular industries under discussion.

DIE ENTWICKLUNG DER DIESELMASCHINE.

By R. Schöttler. Halle (Saale), Wilhelm Knapp, 1925. 50 pp., illus., 11 x 8 in., paper. 3-mk.

Professor Schöttler's monograph gives a concise account of the evolution of the Diesel engine from its beginnings in 1893 to the present time. The development of modern types and of the various details of present designs is covered thoroughly, although briefly, and there are numerous bibliographic footnotes.

DIE FEILE.

By Otto Dick. Berlin, Julius Springer, 1925. 251 pp., illus., 11 x 8 in., boards. 18.-mk.

A handsomely printed, profusely illustrated history of the file, by the engineer of one of the largest German file factories. The book is divided into three parts. Part one, on the history of the file, traces this tool chronologically from the Stone Age to modern times. The second part describes the development of file and rasp cutting machines from the earliest—invented by Leonardo da Vinci in 1503—to the forms in use today. Part three describes the making of files and shows the evolution of the methods. The work is an unusually well planned and executed history of a tool, a model technical history.

GESCHICHTE DER EISENDRAHTINDUSTRIE.

By O. H. Döhner. Berlin, Julius Springer, 1925. 106 pp., illus., 11 x 8 in., cloth. 12-gm.

The author of this handsomely printed little book is a wire manufacturer in Westphalia, the "cradle," as he says, of the wire industry. He traces the manufacture of wire from the earliest times to the beginning of the present century, describing the successive steps by which the industry has advanced to the present stage. Although brief, the book is a careful, critical history, based on long study. The illustrations are carefully chosen from old sources.

DIE GRUNDLAGEN DER HOCHFREQUENZTECHNIK.

By Franz Ollendorff. Berlin, Julius Springer, 1926. 639 pp., diagrs., 9 x 6 in., cloth. 36-r.m.

This textbook is the result of an investigation carried on by the author for the purpose of improving the course of instruction in high-frequency engineering at the Danzig Technical High School. The aim has been not to provide the student with a collection of rules but to give him a thorough grounding in fundamentals, equip him for the independent solution of problems that arise in practice, and especially to teach him to understand scientific literature. Little attention is therefore given to specific machines and commercial varieties of equipment, but rather to topics which are of fundamental physical importance, as, for example, the theory of electro-magnetic radiation.

HANDBOOK OF SAFETY AND ACCIDENT PREVENTION.

By Fred G. Lange. N. Y., Engineering Magazine Co., 1926. 512 pp., illus., graphs, 9 x 6 in., fabrikoid. $5.00.

This handbook aims to bring together the information essential to a proper understanding of the Safety First movement. It gives a general view of the entire field of safety work, describes definite methods of procedure in installing programs for accident prevention, describes many successful methods and provides references to the literature.

INTRODUCTORY ELECTRODYNAMICS FOR ENGINEERS.

By Edward Bennett and Harold Marion Crothers. N. Y., McGraw-Hill Book Co., 1926. 665 pp., illus., diagrs., tables, 8 x 6 in., cloth. $4.50.

In an article published during 1923 in the JOURNAL of the American Institute of Electrical Engineers, Professor Bennett argued the need for separate instruction for engineering students of superior aptitude and those of moderate aptitude; and the provision of introductory textbooks giving a profoundly technical treatment of their subject for the first group and books giving a moderately technical treatment for the second. This text represents the notion that the authors have of the type of introduction to the electrical theory and the electrical principles that are fundamental to design, development, research and technical supervision in the electrical field which students of superior aptitude should receive.

The text is based on the instruction given for seven years at the University of Wisconsin. It aims to facilitate the acquirement of a profound understanding of the subject and is in the form of a connected development in which the observations, definitions, units and laws are taken up in the sequence in which the units of the electrostatic system are defined, each in terms of those preceding it.

RAILWAY TRACK AND MAINTENANCE . . . 4th edition of "Railway Track and Track Work."

By E. E. Russell Tratman. N. Y., McGraw-Hill Book Co., 1926. 490 pp., illus., tables, 9 x 6 in., cloth. $5.00.

A technical account of track construction and maintenance of way, intended for railroad engineers and officials, and for students. It gives the general principles and purposes that underly the design and maintenance of tracks and the systems applicable anywhere in practice. It also gives many details about the equipment, material, appliances and methods used by individual railroads in different parts of the country, under various conditions of traffic and climate. Bridge, signal, telegraph and emergency work are included. This edition has been entirely rewritten.

RECENT ADVANCES IN PHYSICAL AND INORGANIC CHEMISTRY.

By Alfred W. Stewart. 5th edition. N. Y., Longmans, Green & Co., 1926. 312 pp., illus., diagrs., plates, tables, 9 x 6 in., cloth. $6.50.

Contents: The older and the newer chemistry.—X-Ray spectra and automic numbers.—Elements of the rare earths.—Hafnium.—Phenomena of radioactivity.—Disintegration theory and the radioactive series.—Radon, thoron and actinon.—The isotopes.—The isobares.—Analysis of positive rays.—Results obtained with the mass spectograph.—The segregation of isotopes.—Atomic nucleus and its artificial disruption.—Outer sphere of the atom.—Active hydrogen.—Active nitrogen.—Some new hydrides.—Hydrides and the periodic system.—Some effects of intense drying.—Tesla-luminescence spectra.—Conclusion.—Indexes.

The advance in our knowledge in recent years has compelled Dr. Stewart to recast this book so completely that it is practically a new work. New chapters have been written and old text eliminated until but five chapters of the 1920 edition remain.

The new work gives brief, yet comprehensive accounts of recent additions to our knowledge, with numerous references to their literature.

TRAGBARE AKKUMULATOREN.

By Richard Albrecht. Berlin u. Leipzig, Walter de Gruyter & Co., 1926. 135 pp., illus., diagrs., tables, 6 x 4 in., cloth. 1,50 mk.

This book is devoted to portable forms of storage batteries and is confined to the three types—lead, nickel-iron and nickel-cadmium—which have been used commercially.

The author first describes the construction, mode of action and handling of the lead accumulator. This is followed by descriptions of the alkaline accumulators, especially the Edison battery, and a comparison of the two classes. The principal uses of storage batteries, for radio communication, ignition portable lamps and as substitutes for primary batteries are then treated. The book closes with a chapter on methods of charging.

TRAGEDY OF WASTE.

By Stuart Chase. N. Y., Macmillan Co., 1926. 296 pp., 8 x 5 in., cloth. $2.50.

This book is intended to call attention to the waste in industry occasioned by useless and vicious goods and services, by idleness, by unscientific methods of production and distribution and by the waste of natural resources. The author attempts to set forth with some detail the loss through each of these four channels and to estimate the man-power lost through the first three and the waste through the fourth. No solution is suggested, but the book has interest as a vivid, thought-provoking presentation of industrial abuses.

TURBO BLOWERS AND COMPRESSORS.

By W. J. Kearton. Lond. & N. Y., Isaac Pitman & Sons, 1926. 333 pp., illus., diagrs., tables, 9 x 6 in., cloth. $6.00.

Although the turbo blower and turbo compressor have become important in many industrial processes, there have been few serious publications about them in the English language and until now, no book concerning them. In the present work, offered to meet the want, the author has attempted a general treatment which may be useful to students, designers and operating engineers.

A short introduction deals with the principle of the centrifugal compressor and compares reciprocating and rotary compressors. The theory of air compression and the changes of state peculiar to centrifugal compressors are then treated. A theory of the turbo-compressor is then presented, followed by a discussion of the various losses and their influence. Regulating devices are described. Under design, special attention is given to the strength of impellers and the critical speeds of shafts. Methods of testing and some results of tests are given.

UBERSTROME IN HOCHSPANNUNGSANLAGEN.

By J. Biermanns. Berlin, Julius Springer, 1926. 452 pp., illus., diagrs., 9 x 6 in., cloth. 30.-mk.

A rewritten, enlarged edition of "Magnetische Ausgleichsvorgaenge in elektrischen Maschinen." The author discusses transient phenomena in various alternating current systems. Short-circuit processes and their peculiarities are treated in detail as are protective devices. The author is chief engineer of the A E G transformer and high-tension material works and has kept especially in mind the needs of the practising engineer.

VECTORIAL MECHANICS.

By L. Silberstein. 2nd edition. Lond. & N. Y., Macmillan & Co., 1926. 205 pp., 9 x 6 in., cloth. $4.00.

"The main object of this book is to present the chief principles and theorems of theoretical mechanics in the language of vectors and thereby to contribute to the diffusion of the use of vectors," says the author. The book is so arranged that it gives an almost systematic exposition of the chief principles of mechanics which may be used by those acquainted with little more than Alembert's Principle, while to readers thoroughly informed on the subject in its Cartesian form it presents a translation of their knowledge into the shorter vectorial language.

The new edition differs from the first only by the inclusion of some miscellaneous notes.

VIBRATION IN ENGINEERING.

By Julius Frith and Frederick Buckingham. Lond., Macdonald & Evans, 1924. (Reconstructive technical series). 123 pp., diagrs., 9 x 6 in., cloth. 7/6.

The matter of vibration in machinery is frequently of vital importance to makers and users, yet when information is wanted on the subject, it is found that the literature is scattered and difficult to collect. For that reason this book will be of value.

The authors have endeavored to bring together and coordinate the various problems in sound, the strength of materials, mechanics and harmonic motion which enter into the question, and to present the subject of engineering vibration as a whole. They present the subject first from the physical, then from the mathematical point of view, thus making provision for two types of minds.

Addresses Wanted

A list of names of members whose mail has been returned by the postal authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

Past Section and Branch Meetings

SECTION MEETINGS

Boston

Acoustical Engineering, by J. B. Taylor, General Electric Co. Illustrated. March 16. Attendance 80.

Cleveland

Inspection trip to Nela Park Development Laboratories, during which H. D. Blake gave a talk on "New Developments in Incandescent Lamps." After dinner an address was also made by R. W. Shenton on "The Search for the Obvious." Joint meeting with Akron Section. February 18. Attendance 250.

Connecticut

The New England Power Pool, by Samuel Ferguson, Hartford Electric Light Co. March 9. Attendance 110.

The Addition and Subtraction of Colors in Lighting Applications, by A. C. Dick, Westinghouse Lamp Co. March 19. Attendance 50.

Denver

The High Lights of the Gas Industry, by C. A. Harrison, Public Service Co. of Colorado. Luncheon Meeting. January 26. Attendance 60.

The Application of Electricity and Magnetism in Chemistry and Metallurgy, by Dr. M. F. Coolbaugh, Colorado School of Mines. March 19. Attendance 27.

Structural Thermo Insulation, by W. A. Grossman, Intermountain Insulex Co. Luncheon Meeting. March 30. Attendance 75.

Science and the Industries, by Dr. M. I. Pupin, National President, A. I. E. E. March 30. Attendance 800.

Erie

Industrial Electric Heating, by C. P. Yoder, Erie County Electric Co. Illustrated with slides. February 16. Attendance 75.

Mercury-Arc Rectifiers, by D. C. Prince, General Electric Co. Illustrated with slides. March 16. Attendance 65.

Fort Wayne

The Gyroscope, Gyrocompass and Gyropilot, by O. B. Whitaker, Sperry Gyroscope Co. March 18. Attendance 130.

Indianapolis-Lafayette

The Gyroscope, Gyro-Compass and Gyro-Pilot, by O. B. Whitaker, Sperry Gyroscope Co. March 19. Attendance 52.

Communication by Electrical Undulations, by J. Lloyd Wayne, III, Indiana Bell Telephone Co. April 12. Attendance 18.

Lehigh Valley

Power-Factor Correction, by L. W. W. Morrow, *Electrical World*, and *What Diversity Factor and Load Factor Mean to a Community*, by N. E. Funk, Philadelphia Electric Co. March 12. Attendance 102.

Automatic Control of Centrifugal Pumps, by Otto Haentjens, Barrett-Haentjens Co., and

Wallenpaupack Hydro-Electric Development of the Pennsylvania Power and Light Co., by Wm. E. Lloyd, Jr. A dinner preceded the meeting. March 26. Attendance 202.

Los Angeles

General Transportation Situation in Los Angeles, by D. W. Pontius, Pacific Electric Railway Co.;

Industrial Heating, by Max Lee, Westinghouse Elec. & Mfg. Co., and C. J. Cipperly, General Electric Co.; and

Principles of Domestic Electric Refrigeration, by G. H. Hopkins. April 6. Attendance 96.

Lynn

Signal Control for Steam Railroads, by W. H. Reichard. General Railway Signal Co. March 18. Attendance 65.

Madison

The Self-Starting Synchronous Motor, by S. H. Mortensen, Allis-Chalmers Mfg. Co. Joint meeting with University of Wisconsin Branch. March 23. Attendance 50.

Minnesota

Automatic Starters for Synchronous Motors, by G. J. Shavor, Electric Machinery Mfg. Co., and

Synchronous-Motor Applications, by F. H. Milliken, Electric Machinery Mfg. Co. March 29. Attendance 90.

Niagara Frontier

The Quest of the Unknown, by H. B. Smith, Worcester Polytechnic Institute. A dinner preceded the meeting. March 17. Attendance 48.

Oklahoma

Electrical Engineering and State of Oklahoma, by F. G. Tappan, University of Oklahoma;

Oil-Field Electrification, by D. L. Johnson, Westinghouse Elec. & Mfg. Co.; and

Educational Problems, by J. H. Felgar, University of Oklahoma. March 9. Attendance 28.

Philadelphia

Institute Activities, by F. L. Hutchinson, National Secretary, A. I. E. E., and

College, Then What? by Farley Osgood, Consulting Engineer. March 8. Attendance 180.

Pittsburgh

Surge Investigations with the Klydonograph, by J. H. Cox, Westinghouse Electric & Mfg. Co. March 9. Attendance 157.

Oil-Circuit-Breaker Situation from Operator's Viewpoint, by E. C. Stone, Duquesne Light Co., and

High-Power Laboratory and Plans for Test Demonstration, by W. R. Woodward, Westinghouse Electric & Mfg. Co. Dinner preceded the meeting. April 13. Attendance 435.

Pittsfield

Uses of Vacuum Tubes for Purposes Other than Radio, by W. C. White, General Electric Co. March 9. Attendance 55.

The Automobile of Today and Tomorrow, by Herbert Chase, Erickson Co. March 16. Attendance 200.

Portland

Factors Affecting Radio Reception, by C. H. Watson;

The Barrage System of Reception, by A. G. Simson, and

Radio Interference, by Ellis Van Atta, Pacific Power and Light Co. March 17. Attendance 86.

Rochester

Modern Views of Electricity and Matter, by H. C. Reutchler, Westinghouse Electric & Mfg. Co. February 5. Attendance 125.

Railway Electrification—Domestic and Foreign, by H. K. Smith, Westinghouse Electric & Mfg. Co. March 5. Attendance 60.

In the Land of Buddha, by H. B. Smith, Worcester Polytechnic Institute. March 16. Attendance 120.

San Francisco

The Hydro-Electric Power Development at Hetch Hetchy, by N. P. Eckart and J. P. Ost. A dinner preceded the meeting. February 26. Attendance 160.

The Electron Theory in Modern Physics, by M. I. Pupin, National President, A. I. E. E. A dinner preceded the meeting. March 26. Attendance 450.

Saskatchewan

Rural Telephone Development in Saskatchewan, by W. J. Patterson, Minister of Telephones, and

The History of the Telephone, by J. D. Pearl, Northern Electric Co. A motion picture, entitled "From Mine to Consumer," was also shown. March 25. Attendance 125.

Schenectady

Transmission of Pictures by Wire, by B. K. Rhodes, New York Telephone Co. Illustrated with slides. March 12. Attendance 350.

Refrigerators, by A. R. Stevenson, General Electric Co. March 26. Attendance 350.

Seattle

The Development of Sub-Station Practises, by Joseph Hellenthal, Puget Sound Power and Light Co. Illustrated with slides. March 17. Attendance 43.

Sharon

Behind the Scenes, a demonstration presented by the Bell Telephone Co. March 26. Attendance 500.

Among the Fjords of America, by L. O. Armstrong. Illustrated with slides and moving pictures. April 6. Attendance 503.

Spokane

Results of National Survey of Engineering Education, by H. V. Carpenter, State College of Washington. March 19. Attendance 31.

Springfield

The Manufacture of Incandescent Lamps, by H. W. Crafts, General Electric Co. Illustrated with slides and a film. January 25. Attendance 66.

Methods of Medical Treatment of Interest to Electrical Engineers, by Dr. McIver Woody, Gilbert and Barker Mfg. Co. March 22. Attendance 60.

Toronto

Power Transformers, by C. A. Price, Canadian Westinghouse Co. Illustrated with slides. March 19. Attendance 115.

The Self-Propelled Unit Rail-Car, by R. J. Needham, Canadian National Railways. April 9. Attendance 52.

Urbana

Piezoelectricity: Its Scientific and Engineering Applications, by Prof. J. T. Tykociner, University of Illinois. March 11. Attendance 95.

Utah

The Evolution of the Dynamo, by B. F. Howard, Mountain States Telephone & Telegraph Co. March 24. Attendance 43.

Washington

Electrical Apparatus Applied to Dredging Operations, by H. C. Giroux. Illustrated. April 13. Attendance 41.

Worcester

Analogies in Mechanics and Electricity, by Prof. W. S. Franklin, Massachusetts Institute of Technology. March 31. Attendance 50.

BRANCH MEETINGS

Alabama Polytechnic Institute

Business Meeting. March 3. Attendance 23.

Opportunities of the Engineer outside of the Big Corporations, by Prof. Hill. A motion picture, entitled "Letting Dynamite Do It," was also shown. March 10. Attendance 24.

Railway Electrification, by C. E. Haynie, student, and

Orthophonic Reproduction, by J. A. Douglas. March 17. Attendance 18.

Banking and Banking Business, by Prof. A. L. Thomas. March 24. Attendance 26.

Engineering in the Big Cities, by R. O. Lyle, student, and

Rescue Methods of Submarinist, by S. L. Hancock, student. A motion picture, entitled "Beyond the Microscope," was shown. March 31. Attendance 23.

Early History of the Alabama Polytechnic Institute, by Dean John J. Wilmore. April 7. Attendance 19.

University of Arizona

Temperature Change in Induction Watt-Hour Meters, by B. Cottrell;

Elimination of Echoes in Long-Distance Telephone Sets, by T. E. Davis, and

Patents and Patent Laws, by D. M. Dexter. March 6. Attendance 20.

Temperature Rise in D-C. Machines, by Chas. Dunn, and

The Boston Tech Cooperative Course, by R. Fulton. March 13. Attendance 16.

Recent Telephone Development, by Mr. Guyman. March 20. Attendance 20.

Ethics, by Prof. Paul Cloke. Motion picture, entitled "Short Cuts to Quantity Production," was shown. March 27. Attendance 17.

Armour Institute of Technology

Artificial Resuscitation and First Aid, by Dr. J. T. McNamara. January 22. Attendance 101.

Electric Shovels, by M. T. Goetz, A. R. Waehner and C. W. Burcky, students. Illustrated with slides. A talk on the same subject was also given by A .A. Thompson, General Electric Co. February 18. Attendance 28.

Business Meeting. March 4. Attendance 27.

A motion picture, entitled "The King of the Rails," was shown. March 18. Attendance 54.

Brooklyn Polytechnic Institute

Home Lighting, by J. J. McMullan; *High-Frequency Radio Oscillations*, by Lloyd Goldsmith; *Public vs. Private Ownership of Public Utilities*, by Harry Walker; *Lord Kelvin*, by James Dalton and Dominic Chiarello, and *Regenerative Braking*, by Fred Wahlers. March 26. Attendance 25.

California Institute of Technology

A motion picture, entitled "The Story of Anaconda," was shown. March 9. Attendance 8.

A motion picture, showing the manufacture of high-tension cable by the Okonite process, was shown. March 31. Attendance 16.

Case School of Applied Science

General Motor Applications, by Mr. Rogers, General Electric Co. March 2. Attendance 64.

D-C. Engineering Applications, by Mr. Franklin, General Electric Co. March 9. Attendance 59.

Experiences of Student Engineers, by R. C. Putnam. April 7. Attendance 33.

Clemson Agricultural College

Group Versus Individual Motor Drive, by J. R. Cooper; *Electric Elevator Practise*, by B. D. King; *State-Owned Power Again*, by O. M. Harrelson; *Battling Bandits by Broadcasting*, by J. A. Warren, and *Current Events*, by R. H. Mitchell. March 4. Attendance 18.

University of Colorado

Radio Wave Propagation, by Mr. Cassel. April 7. Attendance 50.

Cooper Union

Motion pictures, entitled "Speeding Up Our Deep-Sea Cables," "Telephone Inventors of Today," and "Putting a Telephone Together with Trick Photography," were shown. March 27. Attendance 46.

University of Denver

Principles of the Watt-Hour Meter and Testing, by R. R. McLaughlin, and

The Auto-Valve Lighting Arrester, by A. R. Bitter. March 26. Attendance 16.

The Evolution of the Dynamo, by H. T. Howard, Bell Telephone Co. Illustrated with slides. April 9. Attendance 30.

University of Florida

High-Frequency Alternators, by J. W. Graff. March 22. Attendance 8.

Georgia School of Technology

Motion pictures, entitled "The Wizardy of Wireless" and "Beyond the Miscroscope," were shown. March 23. Attendance 58.

University of Idaho

Motion picture, entitled "Yoke of the Past," was shown. March 16. Attendance 31.

State University of Iowa

Automatic Control for Power Stations, by E. J. Hoetman;

Electric Signs, by P. W. Hubbard, and

Phototelegraphy, by P. A. Loyet. March 10. Attendance 42.

The Value of Student Branches to Engineering Societies, by Prof. W. H. Kavanaugh, University of Pennsylvania. March 17. Attendance 73.

An illustrated talk was given by Dean W. G. Raymond on a report from The Society for the Promotion of Engineering Education. Joint meeting with A. S. M. E. and A. S. C. E. March 31. Attendance 41.

A motion picture, entitled "The Insulation of Wires and Cables," was shown. April 7. Attendance 42.

Kansas State College

Choosing Your Vocation, by Mr. Reece, Bell Telephone Co. Match 25. Attendance 89.

University of Kansas

Synchronous Machines, by Mr. Henningson, General Electric Co. A motion picture on the Okonite process of insulation was shown. March 4. Attendance 75.

The General Electric Test, by A. Havenhill, General Electric Co. Illustrated. March 18. Attendance 65.

Lafayette College

Inspection trip to the Easton Central Office of the Lehigh Telephone Co. March 24. Attendance 20.

Massachusetts Institute of Technology

Water Power Developments in the United States, by Col. William Kelly, Technical Director, N. E. L. A. April 2. Attendance 20.

Michigan State College

Advantages at the General Electric Company of a Tester, by Professor Cory; *The Educational Advantages of the Westinghouse Company and the New York Edison Co.*, by Prof. Naeter; *The Advantages of the Telephone Business from the Educational Standpoint*, by Mr. Osborn, and *The Engineer in Public Utility Work*, by Prof. Kinney. February 25. Attendance 35.

Milwaukee School of Engineering

A motion picture, entitled "The Life of Thomas A. Edison," was shown. March 23. Attendance 30.

Motion pictures, entitled "The Westinghouse Plant" and "The Story of Dynamite," were shown. April 7. Attendance 31.

Montana State College

Fifty Years of Service, by Thomas Neal, and

Railway Electrification Progress During 1925, by H. K. Miller. March 15. Attendance 149.

Development of Electric Lighting, by J. C. Lorimer, General Electric Co., April 1. Attendance 139.

University of Nebraska

Business Meeting. March 5. Attendance 32.

Motion picture, entitled "Temperature and Motor Endurance," was shown. April 1. Attendance 40.

University of Nevada

Meters and Lightning Arresters, by W. C. Smith, General Electric Co. Motion pictures on the life of Thomas Edison were also shown. March 17. Attendance 44.

College of the City of New York

Business Meeting. March 11. Attendance 15.

New York University

Opportunities with the General Electric Company, by Mr. Rugan. Illustrated with moving pictures. March 25. Attendance 53.

University of North Dakota

Pioneers in the Electrical Industry, by Nels Anderson, student,

Rural Transmission Lines, by O. B. Medalen, student, and

The Brunswick Panatrope, by George Russ, student. March 22. Attendance 20.

Northeastern University

Wire Cable and Insulation, by C. D. Davis, Simplex Wire and Cable Co. March 25. Attendance 25.

Ohio Northern University

Business Meeting. March 24. Attendance 36.

Business Meeting. The following officers were elected: Chairman, M. Heft; Vice-Chairman, A. Mathews; Secretary, L. Wadsworth; Treasurer, K. Heming. March 31. Attendance 36.

Ohio State University

Talk by C. F. Kettering, President, General Motors Research Corp. February 26.

Dinner Meeting, at which C. S. Coler, Westinghouse Elec. & Mfg. Co., spoke. March 10.

Developments in the Telephone World, by C. P. Cooper, Ohio Bell Telephone Co. March 12. Attendance 88.

Ohio University

Power Rates and Methods of Fixation, by F. M. McKay, Southern Ohio Power Co. The following officers were elected: President, N. R. Smith; Vice-President, Frank Morgan; Secretary, J. E. Quick; Treasurer, T. R. Root. March 18. Attendance 17.

Oklahoma Agricultural and Mechanical College

The Field of Engineering, by Prof. Edward Kurtz. The following officers were elected: President, W. J. Beckett; Vice-President, Hal Horton; Secretary, Lee Rogers. February 17. Attendance 25.

Business Meeting. Moving picture of Yellowstone Park was shown. March 10. Attendance 47.

Motion pictures, entitled "The Wizardy of Wireless," "The Audion," "Via Radio," and "The Spirit of Service," were shown. April 7. Attendance 80.

University of Oklahoma

Business Meeting. February 25. Attendance 15.

University of Pittsburgh

Public Utilities as a Field for Engineers, by M. R. Scharf, Duquesne Light Co. February 12. Attendance 35.

Engineering Education, by James G. Pattillo, student, and

The Philadelphia Company, by James H. Hoffman, student. February 19. Attendance 29.

Purdue University

Automatic Elevator Control, by R. C. Parker. A motion picture, entitled "Insulation," was also shown, followed by a talk by Prof. Alfred Still. March 30. Attendance 20.

Rensselaer Polytechnic Institute

Automatic Train Control, by W. H. Reichard, General Railway Signal Co. Illustrated with slides. March 17. Attendance 175.

Rhode Island State College

The Electric Clock to be Made Universal, by Mr. Larson; *Mercury-Steam Turbine Generators*, by Mr. Rolston, and *Marine Electric Installations*, by Mr. Wilbourn. March 1. Attendance 15.

The Narragansett Electric Light Plant, by F. R. Smith. March 15. Attendance 17.

Rutgers University

Imagination in Engineering, by H. C. Powell, and

Manufacture of Electrical Porcelain, by Mr. Henderson. March 8. Attendance 21.

University of Southern California

Recent Developments of the General Electric Co., by Mr. Hill. March 4. Attendance 19.

Syracuse University

High-Frequency Induction Furnaces, by N. C. Reed. March 1. Attendance 19.

Long-Distance Transmission, by W. H. Schmidt. March 8. Attendance 18.

Hydrogen as a Cooling Medium, by R. F. Pearson. March 15. Attendance 19.

Voltage Regulators, by R. H. Watkins. March 29. Attendance 18.

Texas Agricultural and Mechanical College

Safety First, by R. K. Eason, student, and

Problems Confronting the Telephone Companies in Large Cities, by C. A. Richardson. March 19. Attendance 51.

University of Texas

Business Meeting. The following officers were elected: President, A. B. Atkinson; Vice-President, V. J. Graham; Secretary-Treasurer, T. S. Gray, and Corresponding Secretary, J. D. McFarland. March 25. Attendance 10.

Virginia Military Institute

Requirements for Recording and Reproducing Sound, by F. M. Barberie, and

Subterranean Heat as a Source of Energy, by R. W. Bouldin. March 16. Attendance 43.

Interior-Frosted Lamps and Corrugated Bulbs, by H. B. Bringhurst;

Training the Staff for Operating the Modern Power Plant, by J. O. Neville, and

Opportunities for the Technical Man in the Pittsburgh District, by J. S. Jamison. April 7. Attendance 46.

State College of Washington

Transformers, by Professor R. D. Sloan. Illustrated with slides. April 1. Attendance 73.

University of Wisconsin

Self-Starting Synchronous Motors, by S. H. Mortensen, Allis-Chalmers Mfg. Co. The following officers were elected: Chairman, Benjamin Teare; Secretary-Treasurer, Neal B. Thayer. March 23. Attendance 52.

Worcester Polytechnic Institute

The Land of Buddha, by Prof. H. B. Smith. Illustrated with slides. March 29. Attendance 45.

University of Wyoming

Business Meeting. April 7. Attendance 16.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.

63 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.

57 Post St., San Francisco, Calif., N. D. Cook, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to **EMPLOYMENT SERVICE, 33 West 39th Street, New York City,** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

ELECTRICAL SALES ENGINEER, for company manufacturing carbon brushes and generators, and carbon specialties. Locations, Kansas City, and Birmingham, Alabama. R-9391-C.

EXPERIENCED TRANSFORMER ENGINEER, familiar with design and practice relating to high-tension, transformers and high-tension, small distribution and special purpose transformers. Must be capable of original work, both theory and practise. Position with a new division of an old line manufacturing company not previously engaged in the manufacture of high-tension electrical apparatus. R-9452.

SALES ENGINEER, to take on line of established renewal products. Must have acquaintances among the engineers of power railway and industrial companies. Exclusive territories in Philadelphia, Pittsburgh, Chicago, Pacific Coast, Buffalo, St. Louis, and Atlanta. R-9511-C-S.

SALESMAN, 25-35, electrical engineering education, who has had experience preferably with one of the large electrical manufacturing companies in the design and sale of electric motors and generators and who has had sales experience. The work will be development of the use of roller bearings in electric motors and generators, and sale of bearings in this market. Considerable traveling necessary. Apply by letter. Headquarters, New Jersey. R-8616-C.

ENGINEER, 30-40, who has had experience as production and schedule engineer in industrial or public utility work. Must be able to plan and direct work of schedule division of engineering department, including the progress and schedule of engineering and construction work, time study, budget records, and production control. Apply by letter. Location, Pa. R-9403-C.

ELECTRICAL ENGINEER, experienced on design transformers. Work will be on electrical welding transformers. Salary $200-$250 a month. Apply by letter. Location, Chicago. R-9157-C.

SALES ENGINEER, to handle distribution and power transformers on salary basis. Must be familiar with public utilities and be resident of Pennsylvania. Apply by letter. Headquarters, Pennsylvania. R-9454.

MEN AVAILABLE

GRADUATE OF M. I. T., 1924, in electrical engineering, age 26. Four months Western Electric Company, sixteen months Telephone Company. Desires position electrical engineering work. New England preferred, but will go anywhere. Salary approximately $35 a week. Available immediately. C-1045.

ELECTRICAL ENGINEER, age 29, with thorough technical education, desires position with consulting firm or public utility, preferably in the West. Three years teaching electrical engineering and four years' experience in test, sales and engineering with General Electric Company. Familiar with power transmissions and related fields. Available after June 15th. C-1118.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER, desires permanent position engineering work Pacific Coast. Two years drafting, designing with electrical manufacturing company, two years substation design, rate engineering large public utility. Good character, pleasing personality, efficient worker; several languages; European university graduate; 27, married. Minimum salary $175.00 a month. Present employed. Available month's notice. C-1109.

RADIO ENGINEER, thoroughly educated, experienced, wants position technical correspondent or development engineer large radio company. Past four years employed as operating engineer, second in charge, in two of New York's broadcasting stations. Designed, constructed, installed a third large broadcasting station Second Radio District. Two years' magazine, special feature writing experience. Not interested position broadcasting station. Available two weeks' notice. Minimum salary $3000. C-1108.

ELECTRICAL ENGINEER, age 27, single, 1923 graduate. Experience with public utilities on the construction, maintenance and operation of transmission and distribution systems. Also familiar with the routine clerical work of both central and district offices. Desires position as electric supervisor, or position leading to executive responsibility. Available on short notice. Location immaterial. B-9897.

ELECTRICAL ENGINEER, college graduate, B. S. degree in E. E., age 29, single. Two and one-half years' Westinghouse test, one month electrical maintenance work in large factory, seven and one-half years' experience electrical construction and supervising work in power houses, substations and transmission lines. Location anywhere in the United States, preference West. Available on week's notice. B-7637.

ELECTRICAL AND MECHANICAL ENGINEER, graduate with honors. G. E. Test, switchboard and central station engineering department; experienced shops, drafting, design and layouts H. T. transmission and protective gear. Desires operating experience with power company. Available May. Location immaterial. B-7623.

ELECTRICAL ENGINEER, four years' design and development experience with large manufacturing company. Would like similar work with a well established company in the Middlewest. College graduate, 28, married. C-1132.

SALES ENGINEER, age 34, married, well acquainted with New England markets, desires to represent electrical manufacturer in this territory. Experienced in selling to dealers, jobbers and manufacturers. Technical education, ten years' engineering and selling experience. Present connection with internationally known manufacturer. Salary and expenses. Available one month. A-1330.

ELECTRICAL ENGINEER, age 32, married, twelve years' experience power plant, substation, industrial, construction, operation, etc., four years with Westinghouse, power plant, substation, switching, metering, drafting, design, control and servicing engineer, eight years industrial and public utilities. Desires engineering, drafting, or supervision in greater New York. Available immediately. B-3172.

SALES ENGINEER-ASSISTANT ENGINEER, married, technical graduate in electrical engineering. Experienced distribution (AC or DC) high voltage transmission, power station design, power systems, also experienced field work and taking off an inventory, and inspection of electrical goods, cable, wire and materials, experience in radio reception, transmission and de-

sign. Good sales personality, convincing talker, thorough workman. B-6558.

ELECTRICAL ENGINEER AND PHYSICIST, age 34, graduate of several leading universities, on instruction staff of well known institution for five years, also commercial experience. Extensive work in electrical and radio development, also patent experience. Position in electrical development, patent work, or with public utility desired. Location, East. B-165.

ELECTRICAL-MECHANICAL DRAFTSMAN, age 27, married, technical education, field and office experience on machinery and power house construction. Available immediately. Anywhere. B-7666.

ENGINEER, E. E., desires position with consulting engineer in industrial development, or as professor. Fifteen years' responsible university positions, including charge of electrical and physics laboratories, development, project, analysis, commercial tests; editorial experience; specialist in illumination. Wants opportunity with future prospects, utilizing broad education, general experience and mature powers. B-2824.

ELECTRICAL ENGINEER, age 33, married, ten years electrical construction experience, desires position as superintendent, or assistant to general manager of construction. Experienced in construction of transmission lines, both overhead and underground, automatic and manually operated high tension substations. Diversified experience in sugar mill and malleable iron foundry practise. At present employed, best of references. Minimum salary $3000. A-3191.

ELECTRICAL ENGINEERING GRADUATE, age 27, married, two years' commercial and engineering experience with telephone and power companies, one year teaching experience as instructor of electricity and mechanical drawing in vocational department of high school. Desires temporary employment. Available June 20th. B-7028.

EXECUTIVE—A man trained as an engineer, experienced as a factory manager, seeks connection offering opportunity for development. Manufacturing experience covers fifteen years on varied line of electrical products. Possesses vision, initiative, tact and the ability to organize an economical factory administration. Salary and percentage bonus based on results preferred. C-1102.

WANTED position as superintendent of power. Fourteen years' experience in construction, operation and maintenance of power plants and transmission systems. Willing to go anywhere in the United States. Available on one month's notice. C-1152.

RECENT GRADUATE ELECTRICAL ENGINEER, desires part time work, designing, estimating, checking, or calculating. Experience in steam power plant electrical construction, also on transmission line survey. Location, Philadelphia. C-1180.

ELECTRICAL ENGINEERING GRADUATE, age 23, single, with one and one-half years electrical testing, and one and one-half years electrical drafting, desires position as electrical draftsman on power plants, or industrial buildings. Location, East. B-6790.

INDUSTRIAL ELECTRICAL ENGINEER, technical graduate, married, wide experience design, repair, construction of electrical equipment as applied to industrial plants, also power plant construction. Desires position with large industrial plant as industrial electrical engineer. Location, Central States. Available on reasonable notice. C-1194.

ELECTRICAL ENGINEER, graduate 1921, desires position with engineering or industrial concern where rapid promotion depends on ability only. Broad experience, operating and distribution problems, industrial electrification, high tension laboratory. At present foreman for test division with leading public utility. Available on two weeks' notice. Age 32, married. Minimum salary $2700. C-1190.

ELECTRICAL ENGINEER, capable graduate E. E., age 29, single. Has had one year's experience on the General Electric Company test, and five years in distribution engineering and construction work. Has specialized in underground engineering and am thoroughly familiar with A. C. low voltage network systems. Has also had considerable experience with electrolysis mitigation. Location immaterial. Available on short notice. C-1191.

EXECUTIVE-MACHINE TOOL ENGINEER, age 38, with all round designing, manufacturing and selling experience, desires connection with eastern company that can take on the manufacture of a semi-automatic production machine. Salary $5500 plus commission or royalty to be arranged. B-9603.

ELECTRICAL AND MECHANICAL ENGINEER, age 40, married, technical university graduate. Fifteen years of practical experience in design, test and operation of A. C. and D. C. motors, generators and switchboard panels; elevator construction, hoisting equipment and installations. Development and production work. Available on reasonable notice. Location, New York City or vicinity. B-5240.

ASSISTANT PROFESSOR OF ELECTRICAL ENGINEERING, age 39, married, desires promotion to associate or full professorship in Middle Atlantic or Midwestern university. Initiative. An all around good teacher. Prefers the advanced subjects. Mathematician. Reading knowledge of German and French. Bachelor's and Master's degrees. Ten years' teaching, three years' practical experience. Salary $3250 to $4000. B-2663.

PATENT ATTORNEY, age 24, electrical engineer, having three years' experience in the Patent Office handling both electrical and mechanical cases, desires to locate with a patent attorney, or with a large manufacturing company in the vicinity of Chicago. C-610.

MANAGER OR EXECUTIVE, age 43, married, seventeen years' electrical experience successful in managing and operating electrical public utility; especially successful in dealing with the public. Desires position in larger field. Salary $6000. C-1179.

ELECTRICAL ENGINEER, fifteen years' experience, mostly in design of alternating current machines. Post graduate technical education. Has done responsible developmental work on transformers, induction motors, direct current motors and new and unusual apparatus. Considerable executive experience. Capable of handling difficult technical problems. Position as executive or responsible technical engineer desired. C-1181.

RAILWAY TELEGRAPH AND TELEPHONE ENGINEER, 36, British, ten years' experience, (also as superintendent), all modern systems, selector, electric staff, condenser-impulse telegraphy, etc. Specialist difficult country. Available May on completion modernization entire system. Desires charge of similar modernization, two or three years, or would accept shorter contract to inspect and recommend with specifications. Location, outside of United States. Fluent French, Spanish. C-2009.

YOUNG MAN, graduating from B. P. I. in electrical engineering, desires a position with an electrical manufacturer or public utility. Especially interested in the field of illumination. Will consider any place that has a chance for advancement. Location, New Jersey or New York City. C-1173.

ELECTRICAL-MECHANICAL ENGINEER, technical graduate, desires connection with contracting or consulting engineering firm contemplating forming an electrical department. Experienced in power and substation design and industrial engineering. At present rehabilitating public utility in South America. C-1141.

ELECTRICAL ENGINEER, desires position as operating or distribution engineer. Age 27, married, technical education. Two years G. E. test, three years electrical superintendent of large industrial plant, and two years with utility company serving 12,000 customers as distribution engineer. Salary $225. Available two weeks' notice. B-9390.

ASSISTANT TO GENERAL ELECTRICAL SUPERINTENDENT of large public utility, available on reasonable notice. Eight years' experience general utility problems, budgets valuations, statistics, accounting, economical engineering investigations, operating problems, high voltage transmission, communication, safety, personnel matters. Sc. B., E. E. degrees, 30, married. Desires permanent position in satisfactory location offering opportunity for advancement. B-3311.

ELECTRICAL ENGINEER, age 27, single, Marquette University graduate 1925, desires opportunity in hydro-electric work. Expects to combine study with work entered. Location immaterial. C-1162.

GRADUATE ELECTRICAL ENGINEER, age 28, married, varied experience in maintenance, drafting, sales engineering, commercial work and operating public utility system. Desires position as assistant manager or superintendent with public utility, or engineer with manufacturing company. Employed at present. Available in thirty days. Location, East Central Atlantic States. Minimum salary $200 a month. B-7827.

ELECTRICAL CONSTRUCTION SUPERINTENDENT, age 38, wide experience electrical construction, operation; ten years construction, eight years general superintendent railways, power plants, substations, general utility work. Present on contract for electrical construction in foreign service. Prefers connection with railway or electrical concern as representative in Latin countries. Technical training. Speaks Spanish, English. Available on five months' notice. C-886.

SALES ENGINEER, who has large acquaintance in the Southern states. Capable of handling any line of heavy apparatus in this district. C-1211.

ELECTRICAL ENGINEER, 27, energetic, inventive and tactful. Past experience: electrical testing and charge of electrical testing apparatus and research, good references. Desires position developing and research of electrical apparatus or machinery. At present employed, but available on two weeks' notice. Greater New York preferred. B-7270.

SALES MANAGER, for manufacturer desiring business relations with central stations and holding companies. Age 39, clean cut aggressive sales engineer with record of sales achievement in public utility field. Graduate engineer. Available in sixty days. Highest references. B-4221.

PROFESSOR IN ELECTRICAL ENGINEERING desired by Harvard University graduate with thirteen years' university teaching experience, and five years of varied and valuable practise, in addition to numerous summers' work. Specialist in high voltage transmission research, theory, design and practise. Important experience with both Westinghouse and G. E. Companies. 43, married, excellent health. C-577-2-C-15.

RADIO ENGINEER AND PRODUCTION MANAGER is open for a connection. For past three years has been acting in those capacities for a well known manufacturer. College education, proven executive ability, clear grasp of audio and radio fundamentals. Well known among the trade fraternities. Best references given and asked for. C-1020.

ELECTRICAL ENGINEER, 33, married, fourteen years' experience design and manufacture electric heating devices, and small specialties, incandescent lamp manufacture, power plant location and finance. Has direct access to large capital for any good proposition in South America and connections in South. Location, Pacific Coast or South America. C-1177-4-A-3.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED APRIL 9, 1926

*ABBOTT, HENRY HERRICK, Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

AMSON, ROBERT IRVING, Engineering Assistant, United Electric Light & Power Co., 56 Cooper Sq., New York, N. Y.

ARCHE, MANUEL PENA, Chief Engineer, Cia Cubana de Electricidad, Inc., Camaguey, Cuba.

AXON, WILLIAM RUSSELL, Correspondent, (Engineering), Westinghouse Elec. & Mfg. Co., 30th & Walnut Sts., Philadelphia, Pa.

*AXTELL, HAROLD BENTON, Long Lines Dept., American Tel. & Tel. Co., 518 N. Beaumont St., St. Louis, Mo.; res., Pasadena, Calif.

*BAKER, ARTHUR WILLIAM, Asst. to Special Engineer, American Electric Railway Association, 292 Madison Ave., New York; res., Brooklyn, N. Y.

BAKER, HALSTED W., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

BAKER, HORATIO ORVILLE, Engineer, Western Electric Co., Inc., 268 W. 36th St., New York, N. Y.

*BARDEN, WILLIAM S., Research Laboratory, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.

BARTON, HERTWELL PAUL SMITH, Jr., Asst. Research Engineer, Postal Telegraph-Cable Co., 253 Broadway, New York; res., Brooklyn, N. Y.

BEACH, WILLIAM CHARLES, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Bloomfield, N. J.

*BECK, ALBERT D., Elec. Engg. Dept., Westinghouse Elec. & Mfg. Co., Cleveland Illuminating Bldg., Cleveland, Ohio.

BELLIS, ALFRED PETER SKILLMAN, Asst. General Manager, Insulated Wire Dept., John A. Roebling's Sons Co., 612 S. Broad St., Trenton, N. J.

BINGEL, GEORGE HENRY, Manager, Engg. Dept., C. H. Stevens Co., 30 Church St., New York; for mail, Brooklyn, N. Y.

BIRD, TRUMAN COLUMBUS, Salesman, Line Material Co., South Milwaukee, Wis.; res., Portland, Ore.

BLACK, HUGH MURRAY, Estimator, Elec. Dept., Allis-Chalmers Mfg. Co., Milwaukee, Wis.

*BLAKEY, LAWRENCE MILLARD, Inspector, Hartford Accident & Indemnity Co., Hartford, Conn.

BLOSER, W. C., Electrical Designer, Thomas E. Murray & Co., 55 E. Duane St., New York, N. Y.; res., Bloomfield, N. J.

BONN, NORMAN E., Research Engineer, Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa.

*BONNER, WALTER FARRINGTON, Laboratory Assistant, Public Service Electric & Gas Co., 21st St. & Clinton Ave., Irvington; res., Montclair, N. J.

*BOOLOS, STEPHEN G., Laboratory Assistant, Brooklyn Edison Co., Brooklyn; for mail New York, N. Y.

BRAKE, WILLIAM JOHN, Asst. Inspector, Light & Power Dept., City of Regina, Regina, Sask., Can.

BRAUE, CHARLES AUGUST, Inspector, Brooklyn, Edison Co., Cor. Johnson & Pearl Sts., Brooklyn; res., Bronx, New York, N. Y.

*BRICE, WILLIAM ARDEN, Dist. Plant Engineer, Illinois Bell Telephone Co., 212 W. Washington St., Chicago, Ill.

*BROWN, ELBERT CHESTER, Asst. Manager, Connecticut Valley Power Exchange, 266 Pearl St., Hartford, Conn.

BROWNE, WILLIAM HAND, 3rd, Operator, McCollom Geological Explorations Corp., 5522 Connecticut Ave., Chevy Chase, D. C.; res., Baltimore, Md.

BUHLER, AUGUST ALBERT, Maintenance Engineering, New York Telephone Co., 227 E. 30th St., New York; res., Yonkers, N. Y.

BURBIDGE, LEONARD, President, R. A. Lister & Co., Inc., 101 Park Ave., New York, N. Y.

BURCHILL, GEORGE HERBERT, Asst. Engineer, Alternating Current Engg. Dept., Canadian General Electric Co., Peterborough, Ont., Can.

BUSWELL, JAY FOWLER, Asst. Control Specialist, Westinghouse Elec. & Mfg. Co., 10 High St., Boston, Mass.

BUTHERUS, FREDERICK ROY, Secretary & Supt., British Sangamo Co., Ltd., Ponders End, Middlesex, Eng.

CALDWELL, EUGENE, Technician, Electrical Dept., American Rolling Mill Co., Ashland, Ky.; res., Huntington, W. Va.

CAMILLI, GUGLIELMO, Electrical Engineer, Transformer Dept., General Electric Co., Pittsfield, Mass.

CAREY, FRANCIS KENYON, Elec. Engg. Dept., Llewellyn Iron Works, 1200 N. Main St., Los Angeles, Calif.

*CARTLAND, FRED WILLIAM, Instructor, Physics Dept., Western State Normal School, Kalamazoo, Mich.

*CASE, JAMES WILBUR, Electrical Engineer, General Electric Co., Bldg. 37, Schenectady, N. Y.

CEDILLO, JUAN, Operator, Substation, Mexican Railway Co., Maltrata, Vera Cruz, Mex.

CENTENO, JOSE GREGORIO, Inspector, Elec. Engg. Dept., Brooklyn Edison Co., 380 Pearl St., Brooklyn, N. Y.

*CHARLES, DWIGHT MOODY, Electrical Engineer, Reliance Electric & Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio.

CHENEY, MARVIN CHAPIN, Ass't to Chief Engineer, Rockbestos Products Corp., New Haven, Conn.

*CHUN, HERBERT H., Development Engineer, Premier Electric Co., Grace & Ravenswood Ave., Chicago, Ill.

CLARKE, SYDNEY OWEN, United Electric Light & Power Co., 201st St. & 9th Ave., New York, N. Y.

COFFIN, LEROY, Electrical Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

*COX, BURNS CALDWELL, Salesman, Carter Electric Co., 7 Auburn Ave., Atlanta, Ga.

CRAIG, PALMER HUNT, Dept. of Physics, University of Cincinnati, Cincinnati, Ohio.

*CRESSON, GEORGE VAUX, Cadet Engineer, Public Service Corp. of N. J., 80 Park Place, Newark, N. J.

CRIST, JAMES A., Toll Engineer, New York, Telephone Co., 700 E. 242nd St., New York, N. Y.

*CROTTY, HAROLD FRANCIS, Asst. Electrical Engineer, Meter & Inst. Engg. Dept., General Electric Co., West Lynn; res., Boston, Mass.

CUMMINGS, ARTHUR EDWARD, Apparatus Inspector New York Telephone Co., 204 2nd Ave., New York, N. Y.

DANIEL, THOMAS ARCHIE, Electrical Engineer; Development Branch, Western Electric Co., Hawthorne Sta., Chicago; res., Maywood, Ill.

DAVIES, WILLIAM BANNING, Inspector, Saskatchewan Telephone System, Balcarres, Saskatchewan, Can.

DAWSON, LEONARD L., Chief Electrician, Elec. Dept., Erie Railroad, 65 Pavonia Ave., Jersey City, N. J.

de BERNARD, EUGEÑIO, Chief Engineer, Compania Cubana de Electricidad, Inc., Contreras 70, Matanzas, Cuba.

de KAY, RODMAN DRAKE, Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

de la GARRIGUE, J. L., Student of Elec. Engg., School of Engineering of Milwaukee, 415-17 Marshall St., Milwaukee, Wis.

*DEMEREC, MARY ZIEGLER, Engineering Assistant, New York Telephone Co., 172 Fulton St., New York; res., Cold Spring Harbor, N. Y.

*DE TAR, DONALD REID, Engineer, Radio Engg. Dept., General Electric Co., Schenectady, N. Y.

DETTWILLER, CHARLES J., Instructor, Works Training Div., Western Electric Co., Inc., Hawthorne Sta., Chicago, Ill.

DONNELLY, JAMES FRANCIS, Chief Electrician, Pennsylvania State Sanatorium, South Mountain, Mont Alto, Pa.

DUA, MEHTAB S., Draftsman, Pacific Gas & Electric Co., 245 Market St., San Francisco; res., Berkeley, Calif.

DUVANDER, BIRGER F. H., Draftsman, Pacific Gas & Electric Co., 245 Market St., San Francisco, Calif.

EGLI, JOHN, Erection Engineer, American Brown Boveri Electric Corp., Camden, N. J.

ELLSWORTH, FRANCIS P., Engineer, Installation Dept., Western Electric Co., Inc., 268 W. 36th St., New York, N. Y.

ETKIN, HARRY ALEXANDER, Development & Test Engineer, General Electric Co., 6801 Elmwood Ave., West Philadelphia; res., Philadelphia, Pa.

FORBES, ALLEN HARRIS, Asst. Professor, Elec. Engg. Dept., Pennsylvania State College, State College, Pa.

FORMAN, HUGH WARDER, Jr., Load Dispatcher, Western Colorado Power Co., Silverton, Colo.

FRANZ, ANTHONY S., Division Electrician, Postal Telegraph-Cable Co., 20 Broad St., New York, N. Y.

FURBISH, CHARLES T., Electrical Engineer, Warren Foundry & Pipe Co., Phillipsburg, N. J.; res., Easton, Pa.

*GEDGE, WILLIAM J., Repair Man, New York Telephone Co., 220 E. 30th St., New York, N. Y.

GIBSON, HENRY JOSEPH, Asst. Engineer, British Electrical Federation, Ltd., 88 Kingsway, London, W. C. 2, Eng.

GODFREY, JAMES HARRY, Small Motor Engg. Dept., Westinghouse Elec. & Mfg. Co., Page Blvd., Springfield, Mass.

GOLIKOFF, ARHIPPE, Technical Representative, "Ural-Platinum Trust," 226 W. 105th St., New York, N. Y.

GOSS, RICHARD COPELAND, Dist. Sales Manager, Ohio Brass Co., 1404 Packard Bldg., Philadelphia, Pa.

GRAYBROOK, HERBERT WILLIAM, Electrical Engineer, Small Motor Engg. Dept., Westinghouse Elec. & Mfg. Co., Page Blvd., Springfield, Mass.

GRIFFIN, THOMAS JOSHUA, Marine Sales Dept., Westinghouse Elec. & Mfg. Co., 30th & Walnut Sts., Philadelphia, Pa.

GUNNARSON, GUSTAF ARVID, Designing Draftsman, Electric Bond & Share Co., 65 Broadway, New York; res., Brooklyn, N.Y.

HAGA, JENS, Engineering Assistant, Brooklyn Edison Co., 44 E. 23rd St., New York; res., Brooklyn, N. Y.

*HAHN, WILLIAM CLINGHAM, Construction Foreman, General Electric Co., 230 S. Clark St., Chicago, Ill.

*HANSTEIN, HENRY BAATZ, Engineering Assistant, Brooklyn Edison Co., 360 Pearl St., Brooklyn, N. Y.

HEWLETT, RALPH C., Student, Pratt Institute, 241 Washington Ave., Brooklyn; res., Hempstead, N. Y.

HICKCOX, TRUMAN WESLEY, Student, Pratt Institute, Brooklyn, N. Y.

HILL, GEORGE JOSEPH, Installation Dept., Western Electric Co., Inc., Hurt Bldg., Atlanta, Ga.

HILYARD, STUART LEONARD, Electrical Engineer, Illinois Pr. & Lt. Corp., 500 Compton Bldg., St. Louis, Mo.

HOUOK, FREDERIC J., Asst. Chief Electrician, Erie Railroad Co., 65 Pavonia Ave., Jersey City, N. J.

HOWLETT, PERCY WILLIAM, Asst. Engineer, Sangamo Electric Co. of Canada, Ltd., 183-185 George St., Toronto, Ont., Can.

*HUGHES, ALBERT ABBOTT, Student Engineer, Radio Corp. of America, Rocky Point, L. I., N. Y.

HUNTER, RUSSELL JAMES, Commercial Engineer, Brooklyn Edison Co., Pearl & Willoughby Sts., Brooklyn, N. Y.

INGLIS, J. G., General Engg. Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

INOUYE, RYOICHI, Research Engineer, Hitachi Engineering Works, Sukegawa, Ibarakiken, Japan.

JACZKO, JOSEPH, Draftsman, Westinghouse Elec. & Mfg. Co., Sharon, Pa.

JOHNSTONE, HENRY HUGH, Operator, Cleveland Electric Illuminating Co., Cleveland, Ohio.

JONES, HARRY PRIMROSE, Electrical Designer, Philadelphia Electric Co., 1000 Chestnut St., Philadelphia; res., Norristown, Pa.

KANEB, BETON MICHAEL, Electrical Engineer, American Steel & Wire Co., 767 Milbury St., Worcester, Mass.

*KELLER, EDWARD JOSEPH, Instructor, Electrical Construction Dept., Roxborough High School, Ridge Ave. & Fountain St., Philadelphia, Pa.

*KENAH, ROLAND M., General Engg. Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., New Brighton, Pa.

*KINCKINER, RALPH A., Asst. Test Engineer, Philadelphia Electric Co., Beach & Palmer Sts., Delaware Sta., Philadelphia, Pa.

KINSELLA, RICHARD HAROLD FRANK, Engg. Estimator, Brooklyn Edison Co., Pearl & Willoughby Sts., Brooklyn, N. Y.

*KRAUSS, RALPH A., Cadet Engineer, The Counties Gas & Electric Co., 212 DeKalb St., Norristown, Pa.

KRAY, JOHN F., Engineering Assistant, Bell Telephone Co. of Pa., 261 N. Broad St., Philadelphia, Pa.

*KRUEGER, RAYMOND A., Asst. Engineer, Wisconsin Valley Electric Co., Wausau, Wis.

LAMBERT, ARTHUR WILLIAM, Plant Maintenance, Pacific Tel. & Tel. Co., 444 Bush St., San Francisco; res., Berkeley, Calif.

LANGLOIS, RICHARD, Chief Engineer, Technical Dept., Ateliers de Construction Electriqie de Jeumont, Jeumont, Nord, France; for mail, Belgium.

LEDERHAUS, HERMAN WILLIAM, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Whitestone, N. Y.

LEE, D. WEBSTER, Inspector of Electrical Construction, Dept. of City Transit, 12th & Chestnut Sts., Philadelphia, Pa.

LEESON, GEORGE EDWARD, District Inspector, Saskatchewan Government Telephones, Yorkton, Sask., Can.

LEONARD, EMERY MAYROW, Designing Transformer, Pittsburgh Transformer Co., Pittsburgh, Pa.

LEVY, MAURICE LEWIS, Asst. Radio Engineer, Stromberg-Carlson Tel. Co., 1060 University Ave., Rochester, N. Y.

LEWIS, JOHN GEESEY, Asst. Chief Engineer, Potomac Edison Co., Cumberland, Md.

LEYDEN, ARTHUR F., Plant Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Brooklyn, N. Y.

*LIPPINCOTT, CHARLES DUDLEY, Underground Engineer, Adirondack Power & Light [illegible] Broadway, Schenectady, N. Y.

LIPPMAN, WILLIAM O., Chief Inspector, Westinghouse Elec. & Mfg. Co., Springfield, Mass.

*LORJE, HERMAN, Budget Engineer, Empire Companies, Bartlesville, Okla.

*LOW, HERBERT MELVIN, Electrician, Andes Copper Mining Co., 25 Broadway, New York, N. Y.

LUND, ALFRED ERIK, Danish Consulate, Bridge St., New York, N. Y.

LYSTER, MERTON SOLOMON, Student Bridge Man, The Pacific Tel. & Tel. Co., 140 New Montgomery St., San Francisco, Calif.

MAHL, JOHN AUGUST, Draftsman, Pacific Gas & Electric Co., 245 Market St., San Francisco, Calif.

MARTINGELL, LAWRENCE WILLIAM, Tester, Cansfield Electric Works, 260 Geary Ave., Toronto, Ont., Can.

MATHEWS, EARL CYRUS, Electric Inspector, U. S. Shipping Board, 207 S. Broadway, Los Angeles; res., Lynwood, Calif.

*McCANDLESS, CARROLL FRED, Meter Dept., Consumer's Power Co., Western Ave., Muskegon; for mail, Ludington, Mich.

McCORMICK, HAROLD VOORHIES, with C. L. Stevens Co., 1st National Bank Bldg., Boston, Mass.; res., Queens Village, N. Y.

McKEARNEY, JOHN JOSEPH, Asst. to Division Electrician, Postal Telegraph-Cable Co., 20 Broad St., New York; res., Central Islip, N. Y.

*MENDENHALL, HALLAM EVANS, Graduate Student, California Institute of Technology, Pasadena, Calif.

MICHAEL, JOHN HADJI, Apprentice, Switchgear Dept., Allis-Chalmers Mfg. Co., West Allis, Wis.

MILMOE, ROBERT, Engineer, Knoxville Power & Light Co., Knoxville, Tenn.

MODLIN, WALTER GEORGE, Division Substation Engineer, Public Service Electric & Gas Co., 75 River St., Newark, N. J.

MOES, GERLACUS, Experimenter, Electrical Laboratory, Simplex Wire & Cable Co., Sidney St., Cambridge; res., Brookline, Mass.

MOXON, ALFRED WILLIAM, Student, Pratt Institute, Brooklyn, N. Y.

*NAKAMOTO, HAYATO, Testing Laboratory, Public Service Electric & Gas Co., 21st St. & Clinton Ave., Irvington; res., Newark, N. J.

NEANDER, MICHAEL T., Engineer in Charge of Construction, First State Electric Power Station, 76 Obvodny Kanal, Leningrad, Russia.

*NICHOLSON, ROBERT FRANCIS, Instructor, Elec. Engg. Dept., Catholic University of America, Brookland; res., Washington, D. C.

NORWIG, JOHN, Jr., Engineering Assistant, United Electric Light & Power Co., 56 Cooper Sq., New York; res., Brooklyn, N. Y.

O'BRIEN, EDWARD CHARLES, Salesman, J. J. O'Brien & Son, 154 E. 23rd St., New York, N. Y.

ONO, YUTAKA, Designing Engineer, Shibaura Engineering Works, Shibaku, Tokyo, Japan.

*ORCUTT, HOWARD S., Engineering Assistant, United Electric Light & Power Co., 56 Cooper Sq., New York, N. Y.

OSBORN, AMBROSE LESTER, District Traffic Supt., Southern New England Telephone Co., 73 Washington St., New London, Conn.

OSBURN, MERVYN PHILLIP, Student Apprentice, Employees Relations Dept., Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

OUELLETTE, EDWARD F., Operator, Main Power House, Ford Motor Co., 1581 Henry St., Detroit, Mich.

PAGANO, LAWRENCE ANTHONY, Engineering Assistant, Brooklyn Edison Co., Inc., 14 Rockwell Place, Brooklyn, N. Y.

PAINTER, CHARLES LEROY, Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Pitcairn, Pa.

*PATRICK, PAUL DAVID, Underground Engr. Dept., Philadelphia Electric Co., 23rd & Market Sts., Philadelphia, Pa.

PAUL, HERBERT F., Tester, The Electric Controller & Mfg. Co., 2700 E. 79th St., Cleveland, Ohio.

PETERS, A. W., Asst. Engineer, Operating Dept., Shawinigan Water & Power Co., 83 Craig St., W., Montreal, Que., Can.

PIKE, ARTHUR THORNDIKE, Telephone Engineer, Western Electric Co., Inc., 268 W. 36th St., New York, N. Y.

PIKE, WILLIAM KENNETH, Chief Clerk, Service Dept., Westinghouse Elec. & Mfg. Co., 395 Liberty St., Springfield, Mass.

POLLARD, ARCHIBALD HAYWARD, Electrical Engineer, International General Electric Co., Schenectady, N. Y.

POLLEY, LOUIS PALMER, Distribution Engineer, Puget Sound Power & Light Co., 1306 "A" St., Tacoma, Wash.

POWELL, JOHN HAYES, Field Engineer, R. E. Berry, 165 Manchester St., Christchurch; for mail, Lyttelton, New Zealand.

*PURUCKER, RALPH ERHARDT, Student, University of Wisconsin, Madison; res., Jefferson, Wis.

QUEVEDO, ANTONIO, Sales Engineer, Westinghouse Electric International Co., Havana, Cuba.

RATHGEBER, MORTIMER DEMOREST, Substation Operator, Potomac Electric Power Co., Washington, D. C.

RICKS, HUBERT MORTIMER, Sales Engineer, Weston Electrical Instrument Corp., 50 Church St., New York, N. Y.

RIDDLE, WILLIAM LEWIS, Electrical Engineer, Westinghouse Elec. & Mfg. Co., Springfield, Mass.

ROBB, FRANK HAROLD, Supt., Automotive Service, Westinghouse Elec. & Mfg. Co., 395 Liberty St., Springfield, Mass.

ROCKEFELLER, HARRY C., Sales Correspondent, Westinghouse Elec. & Mfg. Co., East Springfield, Mass.

ROSS, WILLIAM, Salesman, James Martin, 134 W. 52nd St., New York; res., Bronx, New York, N. Y.

RUBEL, WALTER L., Designing Engineer, Memco Engineering & Manufacturing Co., 381 Hamilton St., Long Island City, N. Y.

SAMPSON, GEORGE HENRY, Electrical Engineer, Nashua Manufacturing Co., Nashua, N. H.

SAUL, HARRY KARL, Economy Glass Co., Morgantown, West Va.

SAURWEIN, VALENTINE EMIL, Schedule Supervisor, Ohio Bell Telephone Co., 6205 Carnegie, Cleveland, Ohio.

SCHMIDT, HARRY, In charge, Switchboard Dept., U. S. E. M. Co., 505 W. 42nd St., New York; res., Brooklyn, N. Y.

SCHNUG, GEORGE, Draftsman, Pacent Electric Co., Inc., 91, 7th Ave. New York; res., Glendale, N. Y.

SCHROEDER, RUSSELL FRANKLIN, Inspector, Brooklyn Edison Co., Johnson & Pearl Sts., Brooklyn, N. Y.; res., North Bergen, N. J.

SCHULTZ, STANLEY WILLIAM, Commonwealth Edison Co., 28 N. Market St., Chicago, Ill.

SEAWARD, EDGAR SMITH, Storage Battery Engineer, Gould Storage Battery Co., Depew, N. Y.

SEKI, YOSHINAGA, Electrical Engineer, Mitsubishi Electrical Engineering Co., Nagasaki, Japan.

*SHAW, RONALD HAYDEN, Student Engineer, Tampa Electric Co., Tampa, Fla.

SINGER, ROBERT H., Asst. Engineer, The Union Gas & Electric Co., 1107 Plum St., Cincinnati, Ohio.

SKINNER, DEAN C., Electrical Draftsman, Youngstown Sheet & Tube Co., Youngstown, Ohio.

SMITH, ADAM W. SIMPSON, Engineering Apprentice, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

SMITH, EUGENE C., Plant Electrician, Russell Mfg. Co., Middletown, Conn.

SPANN, RANSOM D., Captain, Coast Artillery Corps, U. S. A., 39 Whitehall St., New York, N. Y.
SREENIVASAN, KASI, Post Graduate Research Work, Radio Lab., Dept. of Elec. Technology, Indian Institute of Science, Hebbal P. O., Bangalore, India.
STACK, SYDNEY S., Laboratory Assistant, General Electric Co., Schenectady, N. Y.
STROD, ARVED JOHN, Engineer, Miscellaneous Engg. Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.
STUART, BRIGT ODMUNDSEN, 3824 Waldo Ave., New York, N. Y.
STUFFT, JOHN W., Sales Correspondent, Westinghouse Elec. & Mfg. Co., 150 Broadway, New York, N. Y.
STYRMOE, JAMES EDWARD, Welding Specialist, Westinghouse Elec. & Mfg. Co., 2211 W. Pershing Road, Chicago, Ill.
SUPPERS, HOBART GARRET, Engineer of Electrical Tests, John A. Roebling's Sons Co., Trenton, N. J.
SUTTON, CLARK A., Electrical Draftsman, Bethlehem Steel Corp., Bethlehem, Pa.
SWAZEY, HOLLIS A., Tester, New York Edison Co., 92 Vandam St., New York, N. Y.
TAYLOR, S. BLACKWELL, Engineer, Reliance Electric & Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio.
TEKER, LOUIS, Purchasing Agent, Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa.
TOETZ, FRED WILLIAM, Chief Electrician, Emsco-Derrick & Equipment Co., 6701-7101 S. Alameda St., Los Angeles, Calif.
*TRACHTMAN, HARRY, Electrician, Bronx Elec. Co., 612 Crescent Ave., Bronx, New York, N. Y.
TURNER, C. MAYNARD, Asst. Engineer, Dept. of Public Works, State of Washington, Capitol Bldg., Olympia, Wash.
*VADEN, THOMAS HUNT, Asst. Supt., Eastern Div., Alabama Power Co., Anniston, Ala.
VON SNEIDERN, ARNE A., Laboratory Assistant, General Electric Co., Schenectady, N. Y.
WADLEK, JOSEPH, Draftsman, Transformer Engg. Dept., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
*WALLER, JOHN L., Development & Research Laboratory, Rome Wire Co., Rome, N. Y.
*WECKWERTH, HERBERT F., Electrical Engineer, City of Kaukauna, Kaukauna, Wis.
*WELSH, WILLIAM ELWORTH, Division Supt. of Transmission, Penn. Power & Light Co., Ashley, Pa.
WENDLER, HOWARD J., Electrical Designer, Public Service Production Co., 27 Mechanic St., Newark, N. J.
*WHITE, HARRISON GATES, Sales Engineer, Mancha Storage Battery Locomotive Co., 1909 S. Kingshighway Blvd., St. Louis, Mo.
WILFLEY, VERNON BAILEY, Electrical Engineer, Westinghouse Elec. & Mfg. Co., Wilkinsburg, Pa.
WILKINSON, THOMAS ALEXANDER, General Engineer, Westinghouse Elec. & Mfg. Co., 150 Broadway, New York, N. Y.
*WILLIAMS, F. REID, Engineer, Dixie Power Co., Cedar City; for mail, Veyo, Utah.
*WILLIAMSON, ROBERT BLANCHARD, Field Engg. Work, General Railway Signal Co., Rochester, N. Y.
WITTENBERG, ALBERT J., General Foreman, Brooklyn Edison Co., Inc., 14 Rockwell Place, Brooklyn, N. Y.
*WOLF, ALEXANDER, Investigation & Research Section, Philadelphia Electric Co., Philadelphia, Pa.
*WOODWARD, JOHN EGGLESTON, Student Engineer, Standard Oil Co. of New Jersey, Bayway Refinery, Elizabeth, N. J.
*WURST, LEROY LAWRENCE, Field Engineer, Public Service Co. of Northern Illinois, 198 N. Schuyler Ave., Kankakee, Ill.
WYATT, RALPH M., Methods Engineer, Western Electric Co., Inc., 268 W. 36th St., New York, N. Y.
YOUNG, THOMAS JOSEPH, Member, Technical Staff, Research Dept., Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
ZELLWEGER, F., Asst. to Electrical Engineer, Schweitzer & Conrad, Inc., 4421 Ravenswood Ave., Chicago, Ill.
*ZIMMERMANN, ANDREW GEORGE, Switchboard Engineer, The Pacific Tel. & Tel. Co., 140 New Montgomery St., San Francisco, Calif.

Total 205

*Formerly enrolled students

ASSOCIATES REELECTED APRIL 9, 1926

BROWN, EDWARD CLAUDE, Consulting Engineer, Edward C. Brown Co., 200 Devonshire St., Boston, Mass.
HACKBUSCH, RALPH ANTHONY, Service Dept., Canadian Westinghouse Co., Ltd., 366 Adelaide St., W., Toronto, Ont., Can.

MEMBER ELECTED APRIL 9, 1926

ZELENTSOFF, JICHAEL EUGENE, Professor, Electrotechnical Institute, Pessochnaia 7, Leningrad, Russia.

FELLOW ELECTED APRIL 9, 1926

CHERNYSHOFF, ALEXANDER, Professor, Polytechnic Institute, Leningrad, Sosnowka, Russia.

TRANSFERRED TO GRADE OF FELLOW APRIL 9, 1926

FLEAGER, CLARENCE E., Chief Engineer, Pacific Telephone & Telegraph Co., San Francisco, Calif.

TRANSFERRED TO GRADE OF MEMBER APRIL 9, 1926

CLARK, JOHN A., Research Engineer, Weston Electrical Instrument Corp., Newark, N. J.
CUNNINGHAM, R. E., Operating Electrical Engineer, Southern California Edison Co., Los Angeles, Calif.
DAVIES, HAROLD C., Station Section, Elec. Engineering Dept., Hydro Electric Power Commission, Toronto, Ont., Can.
FIELDS, ERNEST S., Asst. Electrical Engineer, Union Gas & Electric Co., Cincinnati, O.
GRAHAM, FRANK H., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.
HALE, WILLIAM K., State Electrical Engineer, Mountain States Tel. & Tel. Co., Denver, Colo.
HARRIS, IRVING C., Consulting Engineer, Cone and Harris, Los Angeles, Calif.
HEALY, EDWIN S., Transmission Engineer, Electric Bond & Share Co., New York, N. Y.
HINSON, N. B., System Planning Engineer, Southern California Edison Co., Los Angeles, Calif.
HORN, A. F. E., Manager, General Electric Co., Washington, D. C.
JOHNSON, JAMES A., Works Manager, Canadian Crocker Wheeler Co., Ltd., St. Catherines, Ont., Can.
JONES, ARTHUR L., District Engineer, General Electric Co., Denver, Colo.
PUBLOW, CEDRIC F., Asst. Station Engineer, Hydro Electric Power Commission, Toronto, Ont., Can.
SIMPSON, WILLIAM L., Division Engineer, Postal Telegraph-Cable Co., Chicago, Ill.
SOULE, WILLIAM H., Electrical Superintendent, Mond Nickel Co., Coniston, Ont.
STARR, JAMES H., District Engineer, Condit Electrical Manufacturing Co., St. Louis, Mo.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held April 5 and 26, 1926, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

BEDELL, FREDERICK, Professor of Applied Electricity, Cornell University, Ithaca, N. Y.
BOYAJIAN, ARAM, Electrical Engineer, General Electric Co., Pittsfield, Mass.
DAVIDSON, WARD F., Research Engineer, Brooklyn Edison Co., Brooklyn, N. Y.
MARRIOTT, ROBERT H., Consulting Engineer, New York, N. Y.
McQUARRIE, JAMES L., Chief Engineer, International Standard Electric Corp., London, England.
ORSETTICH, ROBERT, Chief Engineer, Wilton Works of General Electric Co., Birmingham, England.
RICHARDS, WILLIAM E., Supt., Electrical Dept., Toledo Edison Co., Toledo, Ohio.
THOMAS, GEORGE N., Contract Engineer and Supt. of Construction, Canadian General Electric Co. Ltd., Toronto, Ontario.

To Grade of Member

BULLARD, WILLIAM R., Assistant Engineer, Electric Bond & Share Co., New York, N. Y.
CAMPBELL, THADDEUS C., Telephone Engineer, Systems Development Dept., Bell Telephone Laboratories, New York, N. Y.
HENTZ, ROBERT A., Electrical Engineer, Philadelphia Electric Co., Philadelphia, Pa.
HODTUM, JOSEPH B., Sales Engineer, Pittsburgh Transformer Co., Pittsburgh, Pa.
HULL, BLAKE D., Transmission & Protection Engineer, Southwestern Bell Telephone Co., St. Louis, Mo.
KEPHART, CALVIN I., Senior Examiner (Valuation), Interstate Commerce Commission, Washington, D. C.
KNUDSEN, H. A., Electrical & Mechanical Engineer, East Bay Municipal Utility District, Oakland, Calif.
KOCH, M. McK., Supt. Electric Distribution, Public Service Co. of Colorado, Denver, Colo.
LOUIS, H. C., Chief of Research & Test, Consolidated Gas Electric Light & Power Co., Baltimore, Md.
MacNAUGHTON, A. K., Supt. of Distribution, Blackstone Valley Gas & Electric Co., Pawtucket, R. I.
McCLELLAN, LESLIE N., Electrical Engineer, U. S. Bureau of Reclamation, Denver, Colo.
McILVAINE, H. A., Engineer, Cleveland Vacuum Tube Works, Cleveland, O.
McROBBIE, HENRY W., Supt. Substations, West Penn Power Co., Connellsville, Pa.
NELSON, EDWARD L., Engineer, Bell Telephone Laboratories, New York, N. Y.
NORRIS, ERIC D. T., Technical Electrical Engineer, Ferranti Ltd., Hollinwood, Lancashire, England.
SIMONS, DONALD M., Development Engineer, Standard Underground Cable Co., Pittsburgh, Pa.
SIMS, WILLIAM F., Field Engineer, Generating Stations, Commonwealth Edison Co., Chicago, Ill.
STEBBINS, ALDEN H., Electrical Engineer, Edward Ford Plate Glass Co., Rossford, Ohio.
STINER, H. WRAY, Commercial Engineer, General Electric Co., Cleveland, O.
THOMAS, HERBERT P., Chief Engineer, Southland Electric Power Board, Invercargill, N. Z.
VAN BOKKELEN, WILLIAM R., Chief Engineer, Coast Counties Gas & Electric Co., San Francisco, Calif.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before May 31, 1926.

Alexander, R. W., Commonwealth Power Corp., Jackson, Mich.
Allison, R. S., Niagara, Lockport & Ontario Power Co., Avon, N. Y.
Ambrose, L. O., The Austin Co., Cleveland, Ohio

Anderson, H. L., Commonwealth Power Corp., Jackson, Mich.
Andrews, C. L., The Pacific Tel. & Tel. Co., Portland, Ore.
Anson, E. H., Gibbs & Hill, New York, N. Y.
Anthony, R. B., Penna. Power & Light Co., Mt. Carmel, Pa.
Arbuckel, J. S., American Brown Boveri Electric Corp., Camden, N. J.
Atkinson, J. N., Newfoundland Power & Paper Co., Ltd., Deer Lake, Newfoundland
Atwood, D. S., Llewellyn Iron Works, Los Angeles, Calif.
Bass, O. B., Canadian Pacific Steamships, Ltd., Vancouver, B. C., Can.
Baudry, R. A. M., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Bell, C. R., Cleveland Electrical Illuminating Co., Cleveland, Ohio
Bird, C. A., (Member), The Detroit Edison Co., Detroit, Mich.
Bisazza, R., General Electric Co., Schenectady, N. Y.
Blanch, F. D., General Electric Co., Schenectady, N. Y.
Boura, F. G., West Penn Power Co., Pittsburgh, Pa.
Bowen, W. E., Great Western Power Co., San Francisco, Calif.
Boyer, W. A., General Electric Co., Schenectady, N. Y.
Bragg, A. D., General Electric Co., Schenectady, N. Y.
Branson, A. K., Great Western Power Co. of Calif., Oakland, Calif.
Bryarly, M. M., U. S. Veterans Bureau, Washington, D. C.
Buery, G. E., Peninsula Lumber Co., Portland, Ore.
Burt, A. R., Kansas City Railways Co., Kansas City, Mo.
Butler, M. B., Jr., (Member), American Chain Co., Bridgeport, Conn.
Butterfield, H. S., Atlantic City Electric Co., Atlantic City, N. J.
Campbell, A. E., The Ohio Power Co., Canton, Ohio
Chandler, W. G., Brooklyn Edison Co., Brooklyn, N. Y.
Cheney, W. E., Allis-Chalmers Mfg. Co., Milwaukee, Wis.
Clark, Sherman B., Northwestern Electric Co., Portland, Ore.
(Applicant for re-election.)
Cooper, W. J., Electrician, St. Paul's Hospital, Vancouver, B. C.
Costella, A. P., The Camden Storage Battery Co., Camden, N. J.
Cottrell, W. J., Allied Industries, Inc., Portland, Ore.
(Applicant for re-election.)
Crowell, R. M., Utah Power & Light Co., Salt Lake City, Utah
Damon, A. C., Simplex Wire & Cable Co., Cambridge, Mass.
Daugherty, T. C., New England Tel. & Tel. Co., Boston, Mass.
Davis, J. C., Jr., Edison Elec. Illuminating Co., Roxbury, Mass.
Davison, C., Mexican Telegraph Co., Orizaba, Verz Cruz, Mexico
Dean, C. P., Bell Telephone Laboratories, Inc., New York, N. Y.
de Celis, F., Mexican Light & Power Co., Mexico City, Mex.
Dedek, F. G., Burroughs Adding Machine Co., Detroit, Mich.
Dellinger, F. E., Los Angeles Gas & Electric Corp., Los Angeles, Calif.
Dennis, E. M., Bloedel Donovan Lumber Mills, Bellingham, Wash.
Dickerson, F. A., New York Telephone Co., New York, N. Y.
Dodds, V. G., Aluminum Co. of America, Philadelphia, Pa.
Dowdy, J. W., Electrician & Licensed Marine Engineer, San Francisco, Calif.
Dring, L. G., New York Telephone Co., New York, N. Y.
Drummond, A. J. United Gas Improvement Contracting Co., Philadelphia, Pa.
(Applicant for re-election.)
Eberhardt, P. W., Duquesne Light Co., Pittsburgh, Pa.
Edward, J. A., Hydro-Electric Power Station, Snoqualmie, Wash.
Ehrke, E. B., Pacific States Electric Co., Los Angeles, Calif.
Ellis, D. W., Beech Bottom Power Co., Power, W. Va.
Erickson, E. O., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Ewing, C., Louisville Gas & Electric Co., Louisville, Ky.
Fawcett, O. M., West Penn Power Co., Pittsburgh, Pa.
Feindel, A., New York Edison Co., New York, N. Y.
French, M. A., Charles H. Tenney & Co., Boston, Mass.
Gambitta, A. F., Research Work, 6 W. 28th St., New York, N. Y.
Gardner, E. W., The Pacific Tel. & Tel. Co., Portland, Ore.
(Applicant for re-election.)
Garretson, F. M., Jr., Cooper Hewitt Electric Co., Hoboken, N. J.
Garvin, J. S., (Member), Bell Telephone Labs., Inc., New York, N. Y.
Gauchet, C. E., General Electric Co., St. Louis, Mo.
Grant, A. J., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Gray, J. W., Ohio Northern University, Ada, Ohio
Greene, E. M., Commonwealth Edison Co., Chicago, Ill.
Greene, J. H., Sanderson & Porter, New York, N. Y.
Griffin, G. H., Union Carbide Co., Sault Ste Marie, Mich.
Hadley, G. F., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Haertlein, A., Duquesne Light Co., Pittsburgh, Pa.
Harnett, D. E., Pacent Electric Co., New York, N. Y.
Hartranft, A. C., Philadelphia Electric Co., Philadelphia, Pa.
Henderson, C. L., West Penn Power Co., Pittsburgh, Pa.
Henderson, E. W., Duquesne Light Co., Cheswick, Pa.
Hiltebeitel, J., with H. N. Crowder, Jr., Co., Allentown, Pa.
Hoefflin, A. S., Louisville Gas & Electric Co., Louisville, Ky.
Holtman, J. E., (Member), Westinghouse Elec. & Mfg. Co., Denver, Colo.
Houle, A. V., The New York Edison Co., New York, N. Y.
Hubbard, H. H., Brooklyn Edison Co., Brooklyn, N. Y.
Jarvis, M. M., Burroughs Adding Machine, Detroit, Mich.
Johnson, W. M., Portland Electric Power Co., Portland, Ore.
Judy, E. W., Duquesne Light Co., Pittsburgh, Pa.
Humphreys, D., Newfoundland Power & Paper Co., Ltd., Deer Lake, Newfoundland
Kane, M. P., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Kelly, O. D., West Penn Power Co., Pittsburgh, Pa.
King, J. J., The Pacific Tel. & Tel. Co., Portland, Ore.
Kirchhof, W. H., Philadelphia Rapid Transit Co., Philadelphia, Pa.
Knowles, H. S., Popular Radio Inc., New York, N. Y.
Kucher, A. A., (Member), Westinghouse Elec. & Mfg. Co., Chester, Pa.
Kuriyan, J., Jr., General Electric Co., Schenectady, N. Y.
Lavigne, F. A., Westinghouse Elec. & Mfg. Co., San Francisco, Calif.
Mabee, G. C., Murrie & Co., New York, N. Y.
MacKay, A. T., Western Electric Co., Boston, Mass.
Mathews, P. W., Duquesne Light Co., Pittsburgh, Pa.
Mathewson, D. E., Lockwood Greene & Co., Inc., New York, N. Y.
Matthews, R. F., 214 N. McDowell St., Raleigh, N. C.
McArn, D. G., (Member), Pittsburgh Transformer Co., Pittsburgh, Pa.
McCauley, W. M., Railway & Industrial Engineering Co., Pittsburgh, Pa.
McCreight, R., Jr., Leeds & Northrup Co., Philadelphia, Pa.
McGuire, P. T., Duquesne Light Co., Pittsburgh, Pa.
McIntosh, R. S., Cleveland Railway Co., Cleveland, Ohio

DIGEST OF CURRENT INDUSTRIAL NEWS

NEW CATALOGUES AND OTHER PUBLICATIONS

Mailed to interested readers by issuing companies

Circuit Breakers.—Bulletin 1643A, 32 pp. Describes the general application of oil circuit breakers. Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

Capacitors.—Bulletin GEA-352, 12 pp. Describes capacitors for power factor correction and illustrates concrete savings effected in specific installations. General Electric Company, Schenectady, N. Y.

Transformers.—Bulletins 2052 and 2053, 4 pp. Describe Pittsburgh distribution transformers, single phase and polyphase. Pittsburgh Transformer Company, Columbus & Preble Aves., Pittsburgh, Pa.

Disconnecting Switches.—Leaflets L-25404-8. Describing types RH and RV air-break disconnecting switches. Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

Testing Lead Covered Cable.—Bulletin 101, 16 pp. Describes the facilities for testing, inspection and research work on impregnated paper insulated lead covered cable, of the Electrical Testing Laboratories, 80th Street & East End Avenue, New York.

Cable Joints.—Booklet, 16 pp. Describes patented "Metrolatum filled" high tension cable joints, for cable splices from 11,000 to 66,000 volts. The complete material for each joint is supplied in cartons. Metropolitan Device Corporation, 1250 Atlantic Avenue, Brooklyn, N. Y.

Disconnecting Switches.—Bulletin 501. Describes "Fuswitches" and disconnecting switches. Safety factor, rupturing capacity, flashover, construction and other important features are described in detail. W. N. Matthews Corporation, 3706 Forest Park Boulevard, St. Louis, Mo.

Control Apparatus.—A series of two- and four-page bulletins describing d-c. and a-c. manual and automatic starters, rheostats, crane controls, battery charging and testing equipment. Allen-Bradley Company, 286 Greenfield Ave., Milwaukee, Wis.

Safety Switch.—Bulletins 102, 103 and 104 describe the new "Bull Dog SaftoFuse" switch, being built in capacities of 30 and 60 amperes, 250 volts. The product is briefly described as a fuse carrier with switch contacts which may be withdrawn from the receptacle base. When the carrier is in the "on" position the fuse acts to fill the gap between the blade contacts. This moulded composition unit must be fully withdrawn before the fuses are accessible. Mutual Electric & Machine Company, 7612 Jos. Campau Ave., Detroit, Mich.

NOTES OF THE INDUSTRY

The Cutter Electrical & Manufacturing Company, Philadelphia, manufacturers of I-T-E circuit breakers, has removed its New York office from 1170 Broadway to 12 East 41st Street. The New York representatives of the company are W. C. Jessup, M. B. Cutting and R. C. Heyl.

Lapp Insulator Company, Inc., LeRoy, N. Y., announces the appointment of Harris & Butler, Real Estate Trust Bldg., Philadelphia, as district managers for sale of Lapp products. They will serve eastern Pennsylvania, southern New Jersey, Delaware, Virginia and District of Columbia.

The Robert June Engg. Management Company, Detroit, has moved to larger quarters at 2208 W. Grand Boulevard, Detroit, where it now occupies the entire building. This is the organization's fourth move in four years to larger quarters.

Increase in General Electric Orders.—Orders received by the General Electric Company for the first three months of the present year totalled $86,433,658, Gerard Swope, president, has announced. This compares with $83,846,236 for the first three months of 1925, or an increase of three per cent.

New Diesel Engine.—The Foos Gas Engine Company, Springfield, O., has developed a new Diesel engine with a speed range approximately double that of other designs. The engine weight has been reduced to about 50 pounds as against 100 to 300 pounds per horse power in other Diesel engines. It is also novel in being completely enclosed, and the same is true of its lubrication which is completely automatic.

Static Condensers.—The Westinghouse Electric & Mfg. Company has recently developed a new line of static condensers for individual motor application on motor circuits of 220, 440 and 550 volts for two- and three-phase circuits. The new condenser consists of insulation enclosed in a sheet-metal container and a porcelain terminal housing arranged for conduit connections. The condensers will be displayed at the coming N. E. L. A. Convention at Atlantic City.

Largest Steam Turbine for Commonwealth Edison Company.—A cross-compound turbine, to be rated at 90,000 kw. is being built for installation at the Crawford Avenue Station of the Commonwealth Edison Company of Chicago by the General Electric Company. The turbine will consist of two sections, a high pressure element of 35,000 kw. capacity running at 1800 r. p. m., and a low pressure element of 55,000 kw. at 1200 r. p. m. The addition of the new machine will bring the installed capacity of this station up to 327,000 kw. It is expected that the ultimate capacity of the station will reach 750,000 or even 1,000,000 kw.

The National Carbon Company, Inc., New York, has taken over the plant, inventory and good will of the Corliss Carbon Company, Bradford, Pa., and has also purchased the battery business of the Manhattan Electrical Supply Co., New York, N. Y. The latter purchase includes the battery plants at Jersey City, N. J., and at Ravenna, O., trademarks, patents, etc. The trademark "Red Seal" under which the Manhattan batteries have been advertised will be continued. J. F. Kerlin, president of the Corliss Carbon Company, and formerly assistant general sales manager of the National Carbon Company, Inc., will assume the position of vice-president of the latter company and have complete charge of the sale of all carbon products.

The Wm. Cramp & Sons Ship & Engine Building Company, Philadelphia, has recently secured hydraulic machinery contracts for seventeen units totalling nearly one-half million horse power. The turbines, water wheels and other hydroelectric devices comprising these orders will be installed in Brazil, Japan, Canada and the United States. One contract calls for a 56,000 h. p. impulse wheel, the highest powered of its kind intheworld.

Two 5000 h. p. Moody propeller turbines are intended for the Maribondo Development in Brazil, and two 29,000 h. p. turbines for the Nippon Electric Company, Japan. Two 31,000 h. p. and one 25,000 h. p. units are to be installed in the Norwood Development of the Carolina Power & Light Company. The 56,000 h. p. impulse wheel is being built for the Southern California Edison Company in the San Francisco plant of the Pelton Water Wheel Company, which is owned by the Cramp Company. Two 30,000 h. p. impulse wheels have been ordered by the Feather River Power Company.

The Dominion Engineering Works, Ltd., Montreal, Canadian licensee of the Cramp Company, has secured contracts for three 30,000 h. p. units and three 21,000 h. p. units for the Canadian International Company, and one 28,000 h. p. Moody propeller unit for the Manitoba Power Company.

Requirements for Admission and Transfer

The rapid growth of the Institute during the last few years has necessarily more directly affected the work of the Board of Examiners than that of any other group engaged in A. I. E. E. activities. Forty-two hundred applications were considered during the year ending April 30, 1926, of which one hundred and forty-four were direct admissions and two hundred and fifty-six were transfers to the grade of Member or Fellow. Each of these latter four-hundred cases were reviewed through the careful examination of the complete professional records as submitted by the applicants and the weighing of the statements of the references. Many cases are of course easily disposed of because of the unquestionable eligibility of the applicants to the grades for which the applications are made. The Examiners have found, however, that there is a considerable group, composed of doubtful cases, and it is this group that requires a large part of the Board's time. Many of these cases are doubtful apparently through the failure of the applicants to devote sufficient time and effort to the submission of their records and references.

The electrical field today is of such vast proportions that no group of men, no matter how carefully selected, is competent to judge the importance of an applicant's work where the outline of that work is confined to a simple statement of dates and positions held. Again, two or more positions with exactly the same titles but in different companies, may involve widely different responsibilities. Considering this simple illustration alone, of hundreds that continually arise, the Board of Examiners urges all applicants to furnish records in sufficient detail to give the Board a definite idea of the engineering nature of their work and the degree of responsibility imposed upon them in the execution of that work. References should be selected particularly to cover the period of work on which the application is based. This usually means the last five or ten years, depending upon the grade desired.

If those instrumental in recommending new members will impress these facts on the applicants, and those applying for transfer will keep them in mind, much unnecessary correspondence will be eliminated and action on all applications will be greatly expedited.

The Board of Examiners feel, and every member of the Institute, as well as everyone outside its membership who comes in contact with it, should feel, that admission or transfer in the A. I. E. E. is not a matter to be regarded lightly but one well worthy of every effort that can be put behind it.

Some Leaders of the A. I. E. E.

John J. Carty, pioneer in the development of the telephone art since 1879, was the twenty-eighth president of the American Institute of Electrical Engineers, through the term 1915-1916.

Mr. Carty was born in Cambridge, Mass., April 14, 1861. Starting at Boston, he has been in the Bell System continuously since he left the Cambridge Latin School in 1879. In 1887 he came to New York, and spent two years with the Western Electric Company in cable and switchboard development. In 1889, he went to the New York Telephone Company, of which he became Chief Engineer.

In 1907 he was appointed by Theodore N. Vail to the office of Chief Engineer of the American Telephone and Telegraph Company, and built up the staff through which he directed the engineering and research work of the Bell System. In 1919 he was elected vice president of the company, which position he still holds.

While at Boston, he designed and constructed the first metallic circuit multiple telephone switchboard. During 1889-1891 he published his original researches in inductive interference and upon his experiments is based the theory of transposed metallic circuits. Mr. Carty has numerous telephone inventions to his credit, including the method of the common battery now in general use, and the bridging bell which forms the basis of all farmers' party-line telephones.

Among the engineering advances made under his administration was the completion, on January 25, 1915, of the transcontinental telephone line, making possible, for the first time, the transmission of speech from coast to coast. In the same year, there was accomplished by the staff under his charge the first transmission of speech by radio across the Atlantic Ocean, across the continent to San Francisco and to the Hawaiian Islands.

From the Institute headquarters in New York, he presided over its National Meeting, held May 16, 1916 in six cities; Boston, San Francisco, Atlanta, Chicago, Philadelphia, and New York. By means of the long distance telephone, the members in these remote cities took part in the discussions and in the parliamentary proceedings of a joint meeting—the first of its kind

ever held. In a message of congratulation, President Wilson said: "To conduct such a meeting by telephone and make it possible for men scattered all over the country to listen to the proceedings and participate in them, is certainly a most interesting evidence of the inventive genius and engineering ability represented by the Institute."

In the Officers' Reserve Corps Mr. Carty was a Major and upon the declaration of war, was ordered into active service. Under the direction of the War Department, and with the cooperation of the telephone companies, he organized in the Bell System, twelve battalions of Signal Corps troops. He was promoted to Colonel in the Signal Corps, U. S. A., and served in France on the staff of the Chief Signal Officer of the A. E. F. In cooperation with that officer, he designed the telephone and telegraph system for the American Army in France, and was Signal Officer in charge of communications, American Commission to Negotiate Peace. He received the Distinguished Service Medal from General Pershing in France, the thanks of the French Army and the Cross of the Legion of Honor.

For many years, Mr. Carty has been active in the movement to encourage scientific research in universities and among the industries. He is now Vice Chairman of the Trustees for the National Research Endowment Fund for the support of pure science research, of which Hon. Herbert Hoover is Chairman. He is also a trustee of the Carnegie Institution and of the Carnegie Corporation; a member of the Council of New York University, a member of the National Academy of Sciences and the National Research Council, Honorary Member of the Franklin Institute, from which in 1903 he received the Edward Longstreth Medal for his "bridging bell system;" and the Franklin Medal in 1916, for signal eminent service in science. In 1916 the Edison Medal was bestowed upon him for "work in the science and art of telephone engineering."

The Japanese have decorated him with the Order of the Rising Sun and the Order of the Sacred Treasure, and twice their government extended to him its official thanks for services in connection with the establishment and development of the telephone system there.

He is a Brigadier General in the Reserve Corps of the United States Army, a member of the War Department Business Council, an Honorary Advisor to the Army Industrial College, and national President of the American Signal Corps Association.

Stevens Institute of Technology, and New York University have conferred upon him the honorary degree of Doctor of Engineering; Yale, Princeton, the University of Chicago, Bowdoin and Tufts the degree of Doctor of Science and from McGill University, and the University of Pennsylvania he has received the degree of Doctor of Laws.

Electrification and Farm Prosperity

The unfortunate condition of agriculture in comparison with the exceptional prosperity of other industries in this country in recent years, has called forth many suggested remedies, among which are various bills now before Congress. Prosperity, however, cannot be obtained by legistation except as it may remove obstacles, and the seasonal character of agriculture and the fact that the farmer buys his supplies at prevailing high prices and sells his product in a competitive low market are facts that cannot be legislated away.

A more promising solution of the farmer's difficulties is suggested in an address by General Guy E. Tripp, at the recent N. E. L. A. Convention. A similar solution was also given in an address by President Glenn Frank at the recent Madison Regional meeting of the A. I. E. E. The remedy is the decentralization of industry.

Electric superpower systems are vital to industrial decentralization. Without these systems, industries will not spread out into the country, regardless of advantages to be secured by doing so, but will remain in congested centers. But wherever superpower systems are well developed, power can be secured almost anywhere. Hence, as superpower systems grow, small factories will multiply in the rural districts.

Now, the chief obstacle to the electrification of our farms is the high cost of bringing electric service to them. It usually does not pay to tap a high-tension line and build a low-tension line to take care of the relatively small demand of a few scattered farms, but it frequently does pay to do these things to serve an industry; and when once a service connection is made and a line is built, neighboring farms can then be supplied with electric power at a reasonable cost. Hence, as small factories multiply in the rural districts, more and more farms will be electrified.

No one questions the great value of electric power to the farmer. Give the farmer electric power at a reasonable cost, and he can immediately relieve himself and his family of a large portion of their burden of labor, reduce his costs, make his profits more certain, and, what is of equal importance, raise his standard of living to a level corresponding to that of the city dweller, which will improve the morale of his family, help to keep his children at home and make it more easy for him to secure efficient labor when he needs it.

To sum up, the decentralization of industry will enable the farmer to broaden the earning capacity of his family, increase the business value of his farm and make his home more attractive. It appears, indeed, to be the most promising, if not the only practical influence that will bring agriculture back into step with other American industries and restore prosperity to it. If this can be done, it will mean the elimination of discontent and radicalism from a large and influential proportion of our population.

Abridgment of

The Quality Rating of High-Tension Cable With Impregnated Paper Insulation

BY D. W. ROPER[1] and HERMAN HALPERIN[1]

Fellow, A. I. E. E. Associate, A. I. E. E.

Synopsis.—*During the past five or six years, practically all of the American cable manufacturers have made some changes in their impregnating compound to produce cable having a low dielectric loss. In a number of cases, these compounds were not well chosen. During the same period, some of the operating companies have reduced the thickness of their insulation, resulting in increased dielectric stresses.*

In a number of cases the compounds, and perhaps also the paper that was used, developed faults that were more serious than high dielectric loss. Some cables have been very deficient in dielectric strength and others have developed a new type of trouble which has been termed "ionization;" after a comparatively short time, the operating voltage of such cable had to be materially reduced or the cable replaced, in order to keep the lines in service.

The cable manufactured during this period has generally passed, with a wide margin, the high-voltage tests required by the specifications. Occasionally a lot of cable which passes these tests by a narrow margin will be shipped by a manufacturer and, in such cases, the service record of the cable is unsatisfactory.

The investigations which form the basis of this paper consist of, (a) laboratory tests to determine what high-voltage tests cable, known to be of good quality, will withstand; as well as similar tests on other grades of cable. (b) A careful examination and dissection of samples of the cable as received from the factory and samples removed from lines which have failed in service or which have been in service for a number of years without failure. (c) A comparison of the operating records of the cable with the results of the dissection and examination of the samples and with the factory inspection and tests made on the cable before shipment. (d) Accelerated life tests on long samples of cable having a wide range in quality.

The results of these investigations have been correlated in a manner which permits of the determination of the relative quality of several lots of cable purchased, as well as changes in the specifications which must be made in order to secure satisfactory high tension cable with impregnated paper insulation.

* * * * * * *

INTRODUCTION

AFTER the first few years of experience with impregnated paper-insulated, lead-covered cables, it was thought that a solution of resin in resin-oil would be most suitable for the impregnating compound, and for a number of years this type of compound was used by practically all the American manufacturers, excepting one or two who instead, used a solution of resin in mineral oil. Cables operating above 7500 volts had a large dielectric loss and this caused many failures due to cumulative heating, and made it necessary to operate them at materially smaller currents than permissible on low-tension cables with no dielectric loss. Upon this point being brought to the attention of the manufacturers about 1917, changes were made in the impregnating compound, so that by 1923 the dielectric loss had been reduced to such an extent that its effect in reducing the carrying capacity became almost negligible.

The test results in recent years indicated that the thicknesses of insulation were more than necessary, and accordingly some of the large operating companies purchasing large amounts of cable made reductions in the thicknesses or increased the voltage rating for a given thickness, for the purpose of reducing cost and increasing line capacities, and *thus* increased the dielectric stresses.

The changes in the impregnating compounds and increase in the dielectric stresses developed a large amount of operating troubles on the newer cables, which made it necessary to replace them in some cases, and reduce the voltage in others.

Up to the time that troubles of this kind developed, it had been customary in this country for the cable manufacturers to supply cable to the larger operating companies under a five-year guarantee; and the manufacturers' expense, due to this guarantee, was very slight as most of the claims were due to defective workmanship in the factory or mechanical damage during shipment. The claims for dielectric loss failures were practically eliminated by the A. I. E. E. rule for maximum operating temperature of 85 deg. cent. minus E, with E as rated voltage in kv. About two years ago, the American manufacturers reduced their five-year guarantee to a maximum of two years.

The principal safeguard of the purchasers had rested in the five-year guarantee, as, for cables above 7.5 kv., normal operating voltage, the factory tests were quite perfunctory. The tests served merely to eliminate sections with very defective workmanship, but gave no clue to the quality of the insulation unless it was very bad indeed.

The situation to-day is not greatly different. High-voltage cable which will meet the requirements of all specifications which it has been possible to obtain and which are published in any country, may prove an utter failure within less than one year of operation at its rated voltage. Troubles of this character have

1. Both of the Street Dept., Commonwealth Edison Co., Chicago, Illinois.

Presented at the Regional Meeting of the A. I. E. E., Madison, Wis., May 6-7, 1926. Complete copies available upon request.

not been confined to any one country, manufacturer, or operating company; several cases of such trouble have occurred within the year immediately preceding the presentation of this paper. High-voltage cables that have proved successful in service will pass all requirements of the most recent specifications by margins of the order of 30 to 100 per cent.

As some of the troubles take two or more years in developing, it is entirely possible for the guarantee period to expire before the trouble has become apparent, and then the operating companies are confronted with the proposition of replacing the cable at their own expense or operating it at a greatly reduced voltage. Therefore, the reduction in the guarantee period threw upon the operating companies, with the aid of the manufacturers, the responsibility of devising tests to be made upon the cable at the factory before shipment, to permit of a determination as to whether or not the cable will operate satisfactorily.

Some manufacturers stated that the troubles were due to imperfect impregnation and suggested an ionization test for the purpose of determining which cables were satisfactory. Such a test has been used in recent specifications. Further improvements were made by making moderate increases in the test voltages, but in spite of these slight changes the troubles continue.

This paper describes the methods which have been used in correlating operating experience on about 4,000,000 ft. of high-voltage, three-conductor cable

EXPLANATION

Items 1, 2, 3, 4 and 12, in the absence of definite limitations in the specifications, are based on arbitrary standards established for the guidance of the inspectors. The standards for zero weights would generally have caused the rejection of the cable had they been noted at the factory.

The figures for zero weight for Items 5, 6, 8, 9, and 10 are the requirements of the latest specifications under which the cable was purchased. Full weight is given for Items 6, 8, 9 and 10 for values which would give a large factor of assurance for these qualities. All of these values appear possible of attainment in the present state of the art.

Zero weight and full weight for Items 7 and 11 are about the extreme limits of current American practise. The reasons for Item 11 are given at some length in the paper.

In Item 6 the variation in insulation resistance is based on the largest ratios found for the insulation resistances in the lots of cable as submitted for inspection and tests by the manufacturer and also on the largest ratio of the insulation resistances of the several conductors of any given section in each lot. The weight for this item is divided equally between the values for the lots of cable and for the individual sections. The latter part would disappear for single-conductor cable.

The values for Items 1, 2, 3 and 4 were determined by the inspection at the factory plus information obtained during and after installation. The values for Items 6 to 10, inclusive, were based on the averages of the poorest 20 per cent of the test results. In Items 1, 2, 3, 4, 5, 8 and 12 the values given to each manufacturer were proportioned between zero and base weight and no negative values or bonuses were given on these items. In Items 6, 9 and 10 the values were proportioned arithmetically between zero and full weight and negative values were given if the results were poorer than the values for zero weight, and extra weight was given when the results were better than required for full weight. In Items 7 and 11, negative values were given if the results were poorer than required for zero weight, and no extra value was given if the test results were better than required for full weight.

All values are based on tests and inspection of cable received and accepted by the purchaser.

Note: At least 9 mi. of cable are represented in each of the above ratings.

*Corresponding power factors of dielectric are 6 and 1 per cent at 60 cycles.
The same letters are used in Table II and Fig. 12.
The data were obtained from orders of several thousand feet of cable for columns *M* and *Q*; all other ratings represent several miles of cables.
The explanation under Table I also applies to Table II.

purchased in the past six years from ten manufacturers, with the specification requirements and test results so as to determine what changes and additions should be made in the present requirements.

The object of the investigation upon which this paper is based was to determine just what properties of the insulation were responsible for the failures of the cable in service and to indicate the changes that should be made in the cable specifications in order to materially reduce the number of service failures.

OUTLINE OF METHODS

With such a complex material as impregnated paper insulation having a number of widely different and independent qualities or characteristics, it is practically impossible to compare the products of different manufacturers or different lots from the same manufacturer by any single measurement. The most feasible method of making a reasonably accurate comparison is to adopt the scheme which has been used by engineers with other types of material, that is, to assign weights to the various qualities in the light of past experience, and determine from test or inspection data the percentage of the maximum weight for each item which should be allotted to each manufacturer or lot of material.

Rating tables were first used by the authors to compare the quality of cable indicated by proposals from manufacturers, and later to compare cable actually shipped. At first the ratings were purely relative and did not permit a determination of the amount of improvement which the manufacturers made from year to year. To obtain this amount, the basis was later modified so as to make all of the comparisons on a fixed basis, which meant the adoption of a standard for each of the items considered. Tables I and II give such quality ratings for 13- and 35- kv. cables, respectively. Sixty-cycle current was used for all alternating-current tests.

During this period, it was the practise to make a careful examination of the cable immediately adjacent to each fault and also at the manhole ends of the same section of cable. A detailed study of the results of these examinations as the data accumulated and a careful comparison with the test and inspection data permitted the primary cause of the troubles to be determined. A reference to the corresponding test and inspection data then furnished a basis for determining the base weights for each item, a part of the limits between which the values were proportioned, and the values assigned to the several manufacturers for the various items in the tables.

A perfect method of rating the quality of cables would accurately predict their operating performance

over a wide range of quality of insulation and be equally applicable to the widely varying types of insulation now on the market. In the past few years there has been received cable ranging in quality from poor to excellent. The system of the Commonwealth Edison Company includes over 1300 mi. of 9- to 35-kv., three-conductor cable. For all of this cable the service records test and inspection data on the 800 mi. purchased during the past six years from 10 manufacturers were at hand. In making attempts to devise a quality rating method, each new constructive suggestion was tested by calculating a new rating table with the same original data in the endeavor to secure results which would at least rate the cables in their proper order of merit.

By carefully going over the operating records and comparing them with the test and inspection data and the results of examination of the cable near failures, the rating tables were altered and adjusted so as to bring the final results in accord with the operating experience.

While these studies were in progress, a series of tests had been undertaken to determine what high-voltage tests successful cable should withstand. After some data had been obtained, it appeared perfectly feasible to devise an accelerated life test so that the approximate life of the cable would be indicated by the time that the cable withstood the test. This resulted in another method of rating the quality of cables entirely independent of the first.

High-Voltage Tests

For many years it had been noted that the high-voltage tests which the cables actually withstood when tested at the factory were very much higher than the specification requirements. It had also been noted in a few lots of cable which had proved to be of inferior quality that the high-voltage test results were only slightly higher than the specification requirements. A series of high-voltage tests were, therefore, undertaken to determine what changes should be made in the specification requirements in order to eliminate such inferior lots of cable and, at the same time, allow the manufacturer a reasonable margin.

In the initial tests, the sections of cable were from 100 to 200 ft. long. Previous to applying the voltage, several thermometers were fastened to the lead sheath. With voltage on the cable, the sheath, which was grounded, was examined by the test operators about every 10 minutes, in order to detect points where the sheath temperature was higher than the remaining portions. At these points, which were called "hot spots," an additional thermometer was fastened to the sheath.

After failure occurred, portions of the cable including the fault and perhaps "hot spot" sections would be removed, dissected, and examined. The remaining portion of the length was again tested and this procedure was continued until the cable became too short for further tests. Usually three to seven tests were obtained on each original section of cable.

Several test voltage procedures were tried but most of the tests were made with an initial voltage of 3.6 times normal voltage. As this voltage made the tests unduly long for high grade 13-kv. cable, it was decided to increase the voltage 20 per cent after eight hours, and further increase the voltage 20 per cent after a second eight-hour period. Later, in order to obtain voltage-time curves, tests were made on samples from given sections of cable at a number of voltages maintained constant until failure occurred.

About 8000 feet of cable have been used in making some 250 such tests. The cable was about equally divided between new and second-hand cable. In selecting the sections of cable for these tests, samples were obtained from the cable that had been shipped by the several manufacturers. The sections of second-hand cable were selected so as to obtain similar data for cables of a wide range of quality whose service records were definitely known. The sections of cable used for this purpose were removed on account of failure, external damage, or changes in the transmission system.

Discussion of Quality Ratings

A. Workmanship

The first five items in Tables I and II can be considered under the general heading of workmanship. The information for calculating the values for these items was secured from the factory inspection reports and by examination of samples of cable taken from the ends of sections as received or from the middle of the sections whenever possible. Further information was obtained from time to time by the examination of samples of cable taken from sections removed on account of failures in service or other causes.

A large variety of defects in the conductors, lead, and insulation has been noted in these examinations, and values were assigned to the first four items in the rating tables on the basis of the influence of similar defects found at or near the points of failure which have occurred on test or in service.

Impregnation. The impregnation of paper-insulated cable is satisfactory when:

1. The compound is suitable for the purpose.
2. The impregnating process is performed to completely remove the air and moisture and thoroughly impregnate the insulation, filling all voids in the conductor and in the insulation.

Several tests have been evolved to determine whether the compound will be stable, but such a test was not included in the specifications for the cable covered by this paper. Therefore, Item 4 of Tables I and II refers to the completeness of the impregnation only.

The cable manufacturers contributed considerable discussion on the item of impregnation in commenting on the earlier rating tables, and apparently this dis-

cussion was warranted by the importance of the subject. No satisfactory explanation has been obtained for the marked differences found in the impregnation on the three conductors at one place in the cable nor for the large differences in impregnation throughout the length of one section.

When the insulation is examined near a point where failure, due to ionization has occurred, a pronounced difference in the impregnation is frequently found as, for example, the insulation of one conductor filled with the evidences of ionization while the insulation of the other two conductors will be entirely free from such evidence. In other cases, many evidences of ionization will be found in the insulation of all three conductors near the point of failure, but will be entirely lacking in the manhole ends of the same section of cable.

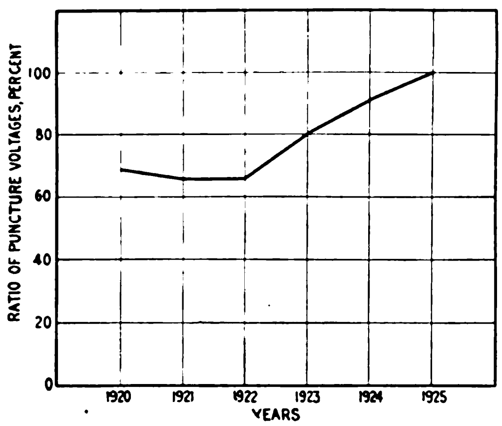

FIG. 1—CHANGE WITH TIME OF RATIO

Puncture voltage on cold bent sample
Puncture voltage on straight sample

Tearing of Paper Tapes in Bending Tests. The routine tests on the cable at the factory include a bending test on an occasional short sample that has been cooled to the minimum operating temperature which, for Chicago, is about minus 10 deg. cent. This is followed by a puncture voltage test and, later by an examination of the paper tapes in a three-foot section of the cable, cut from the middle of the bent portion. The number of tears of the paper tapes are noted and recorded.

During the past few years, the leading American manufacturers have made some marked improvements in the workmanship of the insulation as shown by the paper tapes being applied more smoothly and evenly, the number of torn tapes in the bending test considerably reduced, and the impregnation improved. The extent to which these improvements in workmanship have improved the quality of the insulation is indicated by the reduction in the effect of the bending test on the dielectric strength of the insulation.

The extent of this improvement is shown in Fig. 1 which gives the ratio of the puncture voltage, obtained on the samples that have been subjected to the cold bending test, to the puncture voltage obtained on the straight samples. During the past few years this ratio has risen from about 65 per cent to 100 per cent. It appears therefore that this ratio can be used as an excellent test for workmanship.

B. TESTS ON INSULATION

Insulation Resistance. The insulation resistance test is measured for each of the conductors of each section of the cable, and the greatest present use for the results is as an indication of the uniformity of the manufacturing processes. In Fig. 2 is shown the variation in insulation resistance of 125 consecutive reels as submitted by two manufacturers.

Figs. 3 and 4 show the variation of the power factor of the dielectric with the insulation resistance as obtained from 30 consecutive reels submitted by two manufacturers.

Fig. 5 shows similar data from two different lots of cable submitted several months apart by another manufacturer, and from such data and from other tests showing that no change in the paper was made during the same period, it is evident that the cable manufacturer changed the impregnating compound, a conclusion which has been verified by the manufacturer.

Dielectric Loss at 80 Deg. Cent. For uniformity, the dielectric loss at 80 deg. cent is used for comparison, although for 35-kv. cable it is realized that this is

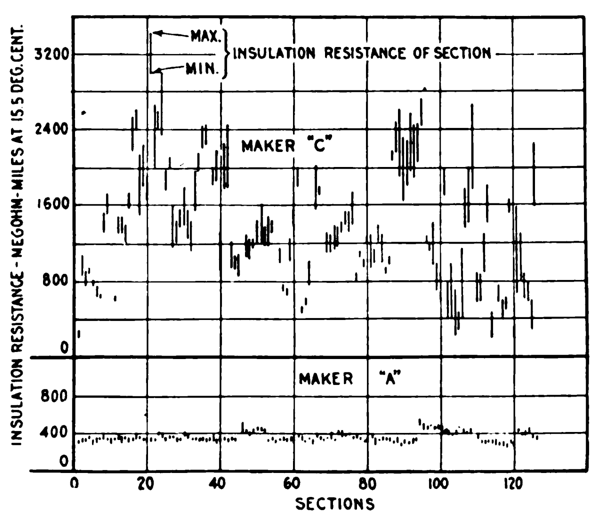

FIG. 2—INSULATION RESISTANCE VS. ORDER OF PRESENTATION OF SECTIONS

500,000-cir. mil, three-conductor, 13-kv. cable made in 1925
Note: The letters used designate the same manufacturer throughout the paper except for Table II and Fig. 12

above the standard maximum operating temperature. However, operating conditions occasionally arise which render it expedient to carry an abnormal load on a cable for a short time rather than open the line and cause interruption of service. The dielectric loss tests at 80 deg. cent. permit the heating of the cable under such abnormal conditions to be predetermined.

The manufacturers are now furnishing cable for voltages up to about 20-kv. with insulation of such

low dielectric loss that this loss does not reduce the carrying capacity of the cable more than one or two per cent. For practical purposes this may be considered negligible. The effect of the power factor of the dielectric on the permissible current loading of cables is indicated by the fact that if the power factor is five per cent then the dielectric losses of three-conductor 13-kv., three-conductor 35-kv., and single-conductor 132-kv., cables of the Commonwealth Edison Company are, about 0.37, 1.75, and 8.0 watts respectively per foot of cable. Since the maximum allowable copper temperature determines the total heat loss in the cable it follows directly that for commercial consideration, as the operating voltage increases, the maximum allowable power factor must decrease. Experience has shown that a dielectric loss of 1.75 watts per foot of the 35-kv. cable does not result in service failures due to cumulative heating. The recent product of some of the leading manufacturers has shown losses materially below this figure.

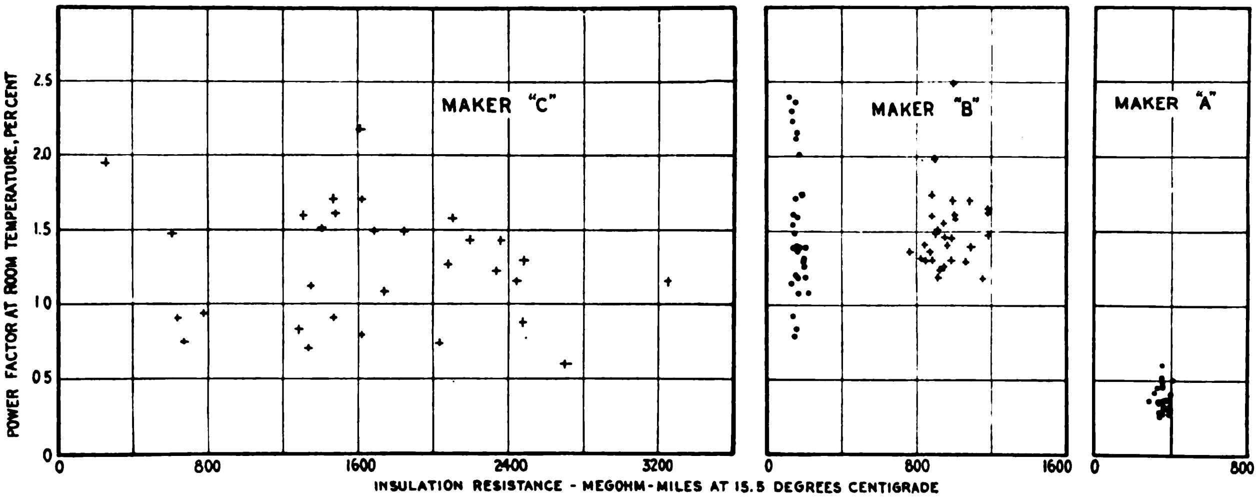

FIG. 3 FIG. 5 FIG. 4

FIGS. 3-4-5—POWER FACTOR VS. INSULATION RESISTANCE

For 500,000-cir. mil, three-conductor, 13-kv. cable, made in 1925 by three manufacturers.

Cables have 18/64 in. insulation between conductors and 14/64 in. insulation between each conductor and sheath

Power factor of dielectric is value obtained at room temperature on each section of cable at 100 volts per mil of insulation thickness. Insulation resistance is average for value for three-conductors obtained by the standard method with direct current

Data are shown for 30 consecutive sections of cable from makers *C* and *A* and for two lots of 30 consecutive sections, each presented several months apart, by maker B.

"IONIZATION" TEST

A test made by measuring the increase in power factor over a certain specified range in voltage, say, from 20 to 100 volts per mil of insulation thickness, is called an ionization test. Several recent specifications require such a test on each section of cable.

Several European manufacturers contend that there should be no increase in power factor for about this change in voltage, while another manufacturer states that increases of one and two per cent for, respectively, single-conductor and three-conductor cables indicates satisfactory impregnation. Probably each statement is correct as applied to the particular combination of paper and impregnating compound in the cable from which the experience was obtained. Fig. 6 shows a number of curves taken from actual tests on samples of commercial cables made by manufacturers that are considered among the leading manufacturers in the world. Some of these cables having the greatest increase in power factor over the specified range in voltage have given the best service, while other cables having a very small increase in power factor have been found

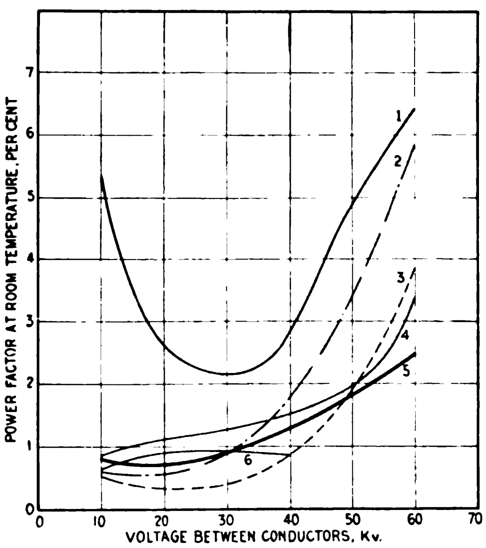

FIG. 6—POWER FACTOR VS. VOLTAGE

For 350,000-cir. mil, three-conductor, 35-kv. cables from various manufacturers

unsatisfactory for service at their rated voltage. In several cases, subsequent tests have developed proof that the impregnating compound was unstable, and this means that a test on the impregnating compound

itself is also necessary in order to insure satisfactory cable.

All these facts indicate the necessity of considerably more information before the proper limits for the increase in power factor can be fixed for the various types of insulation, so that all types will be equally satisfactory.

The visible evidence of high-voltage discharges or of ionization which are found upon dissecting the affected insulation, in the order in which they usually appear to develop in service, are:

a. Waxy flakes and black spots in the compound

b. Black and brown spots in the paper

c. Fern leaf or tree designs in the paper, and pin holes through the paper.

Figs. 7, 8 and 9 show evidences of these defects.

The evidences of ionization are generally found in the largest quantity where the stresses are the greatest, but their distribution throughout the insulation varies widely and appears to be affected by local variations in the impregnation. In the high-voltage tests on samples of cable, the waxy flakes develop only when the tests continue for a long time, of the order of 50 hours or longer; but the other evidences are developed by higher voltages in a much shorter time.

FIG. 7

Waxy flakes and black spots on center filler of three-conductor, 35-kv. cable, impregnated with a heavy grease. Cable was removed after being in service.

FIG. 9—PHOTOMICROGRAPHIC CUT OF (7) DIAMETER MAGNIFICATION SHOWING STRIP OF WAX

Along edge of a tape of the conductor insulation of cable impregnated with a heavy oil

DIELECTRIC-STRENGTH TESTS

High-voltage tests on each section of cable were never intended or considered as a test of the quality of the insulation, but were made for the purpose of eliminating sections having serious defects in workmanship. The first test required by American specifications to insure insulation of the proper quality was the requirement of dielectric-strength test on a short sample about seven years ago.

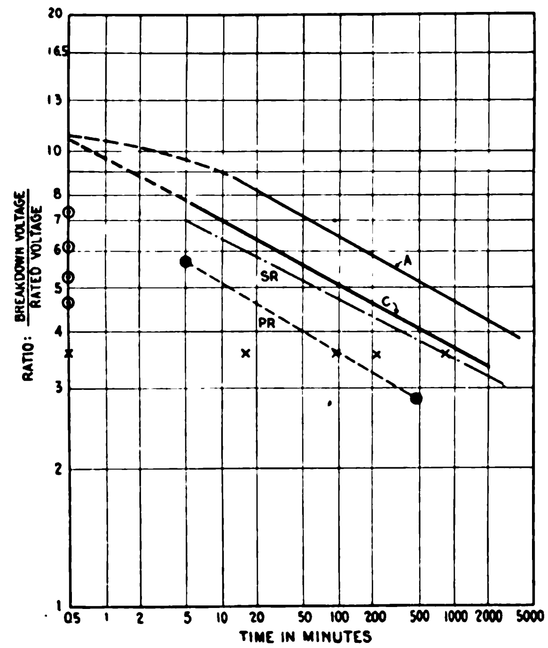

FIG. 10—VOLTAGE-TIME CURVES FOR 500,000-CIR. MIL, THREE-CONDUCTOR 13-KV. CABLES

Curves A and C represent results from tests on 20-ft. samples. Cable A appears quite satisfactory; cable C, inferior and non-uniform, as shown by wide variation in test results.

S R—Suggested test requirements

P R—Present test requirements. •Present specified tests

Typical test results on samples of cables that have proved unsatisfactory in service:

⊙Dielectric-strength tests at factory

×High-voltage tests in Chicago

It has been found that 13-kv., three-conductor cables which met all the requirements of the specifications but which failed on the dielectric-strength test made in accordance with A. I. E. E. standards at a voltage below seven times normal, have been in general quite unsatisfactory. In order to obtain definite information on the proper dielectric strength requirements, a series of high-voltage tests were made on the recent products of two manufacturers, and the voltage-time characteristics thus obtained are shown by lines A and C in Fig. 10. There is also shown typical

results of dielectric-strength tests at the factory and accelerated life tests in Chicago obtained on cable that has proved unsatisfactory in service. Tests on the products of two additional manufacturers give results above line *A*. From these data and the data obtained in factory tests and tests previously described under the subject of High-Voltage Tests, it appears quite certain that if cable will pass the voltage tests corresponding to two or three well separated points on line *S R* in Fig. 10, it will have sufficient dielectric strength to give satisfactory service. However, the cable may be deficient in other respects; for example, in ionization. At the present time it is possible to secure cable from several manufacturers which will average at least 30 per cent higher than the tests so specified and at the same time leave the manufacturer a reasonable margin.

As will be noted from Fig. 10, the test results for the dielectric-strength test for 30 seconds were about the same for cables *A* and *C*, but at lower voltages cable *A* withstood a given test voltage about five times as long as cable C. These data show that the results obtained from a short-time dielectric-strength test are misleading as an indication of the quality of the insulation. In the past, considerable reliance has been placed upon such misleading information regarding the quality of the insulation.

The dielectric-strength tests at the factory and the tests previously described under the heading High-Voltage Tests, when correlated with operating experience indicate that

1. The short-time, dielectric-strengtht est should be made at seven times normal voltage for five minutes; or, if this test introduces pothead or terminal troubles, it will be equally satisfactory to make the test at six times normal voltage for 16 minutes.
2. Satisfactory results can be secured on the short-time test with a sample about 15 ft. long under the lead.
3. A long-time test should be made on samples of the cable, and the requirements for this test should be four times normal voltage for six hours.
4. In order to secure reasonably accurate results on the long-time tests in which the failure may be caused by irregularities that require time to develop, the sample should be about 75 ft. long.

All of the points above mentioned are on line *S R* Fig. 10, and if, for practical reasons, a slight modification is desired in some of these tests, they should be made in accordance with the line.

During the last few months, long-time tests at the factory have been made so as to secure additional information. The test requirements provide that the cable shall withstand 3.2 times normal voltage for eight hours, and the procedure has been that following this test, the voltage has been raised to 5.7 times normal voltage and continued until the cable failed. The samples tested to date have withstood the higher test voltage from about 2 to 12 hours. These data indicate that satisfactory cables which are now being made for 13-kv. service will readily withstand the proposed tests of four times normal for six hours, as well as the test of six times normal for 16 minutes.

The data for lines *A* and *C* were obtained from tests on cables in which the insulation was impregnated with a grease or a heavy oil and their use should be limited to such insulation. The lines indicate that the voltage varies inversely as the seventh root of the time and this law has been found to hold in tests made by F. M. Farmer. It is entirely possible that a different line would be obtained for cable in which the insulation was impregnated with a materially different compound.

Cold Bending Test

Bending-test clauses have been made a part of standard specifications to insure that the cable will not be damaged by the bending incident to its installation in the conduit and training in the manhole. In Chicago, the conditions require that cable installation shall proceed throughout the entire year, except during the very cold days of winter months; and so the specifications for this cable have called for bending tests at temperatures of about minus 10 deg. cent. The need for such a test is indicated by investigations made several years ago which have shown that in 3 per cent of the cable which is in the manholes there are about 20 per cent of the total failures.

Ratio of Puncture Voltage Tests

It has been mentioned under the heading *Workmanship*, that the ratio between the puncture voltage obtained on the sample subjected to the cold-bending test and the puncture voltage obtained on the straight sample, appeared to be an excellent test of workmanship. There is quite a variation in the results of the tests on individual samples; *e. g.*, the puncture voltage on the cold-bent sample is sometimes 10 or 15 per cent higher than that on the straight sample. A study of recent test data shows that if the ratio were required to exceed 75 per cent, it would necessitate good workmanship and still allow an ample margin for the variation between samples.

C. Uniformity of Insulation

This item is a recent addition to the rating tables. In the product of all manufacturers, deficiencies and irregularities are occasionally noted, and some of them can be eliminated only by conscientious workmen and efficient inspectors at the factory.

Non-uniform impregnation is the most common irregularity. Many failures have occurred at points in the cable where there was a marked deficiency in the impregnation. It would be of great assistance in eliminating sections of cable having such deficiencies and in reducing the number of failures which result, if some test which would be a measure of the minimum

quality of the insulation in any section tested could be devised and applied to each section of cable at the factory.

During the high-voltage tests made on three-conductor cable, it was noted that if the voltage was of the order of five or six times normal, a buzzing or crackling noise from the electrical discharges within the insulation could be distinctly heard. At some voltage, not well defined, the internal noise becomes inaudible and, at a voltage somewhat lower, the life of the cable becomes indefinitely long. The indications are that the failures of the insulation which occurred on high voltage tests were brought about by the effect of these internal discharges upon the insulation and that eventual failure of the insulation is inevitable, if the voltage is sufficiently high to cause these internal discharges. If, then, a test could be devised which would indicate the voltage at which the internal discharges begin, this would be an indication of the limiting voltage at the weakest point in the insulation throughout the section of cable tested. Such a test applied to each section of cable would be an invaluable addition to the tests now available, as it would give a direct indication of the minimum quality of any section of cable, whereas, the best that can be accomplished with the present ionization test is to determine the average quality.

The variation in impregnation, plus local defects in workmanship and the resulting variation in the quality of the insulation in a section of cable have been the cause of many failures in service during the last few years in cable that had passed, with a wide margin, all of the requirements of the specifications. Similar variations have been frequently indicated by the results of accelerated life tests on sections of cable; and these tests have shown that if a portion of cable, a few feet long, was removed from a long section of cable, then the voltage rating of the remainder, with the same factor of safety, could be increased by amounts ranging from 15 to over 100 per cent.

Hot Spots

Further evidence of the non-uniformity of the insulation is contained in the record of the hot spots on the lead sheath in the high voltage tests. These hot spots were distributed with great irregularity along most of the sections of cable tested. The temperature of the lead sheath at these hot spots ranged from two or three deg. cent. up to 74 deg. cent. above adjacent portions of the sheath.

In tests on one section of the cable, sudden temperature rises of about eight deg. cent. developed in less than 10 minutes in two hot spots, accompanied by loud crackling and buzzing noises, followed by a disappearance of the noises, and a decrease of about eight deg. cent. in the temperatures. Then the temperatures increased five deg. cent. slowly to the end of the test, when failure occurred elsewhere. A broken filler was found at one of these hot spots.

As the location of the hot spots was recorded by reference to marks made on the original section of cable, it was possible to determine whether the hot spots would reappear at the same locations after an interruption of the test. Sixty per cent of the hot spots which developed in the first tests on 13-kv., three-conductor cable reappeared on subsequent tests. For the 33-kv., three-conductor cable, the corresponding figure was 84 per cent. In those tests where failure was in the cable and the time of the test was sufficient to result in hot spots of two deg. cent. or more above the minimum sheath temperature, 74 and 53 per cent of the failures occurred in hot spots for, respectively, the 35- and 13-kv. cables; 41 and 27 per cent, respectively, of the failures were at the maximum hot spots.

The study of all records shows that, in general, the cable manufacturers that have the best control of their materials and manufacturing processes, as evidenced by the uniformity of test results and inspection data, make the best cable.

Stability of Impregnating Compound

Recently it has been discovered that certain previously used impregnating compounds are entirely unsuitable for use in high voltage cables, that is, cables with average stresses exceeding about 40 volts per mil, and that when such compounds are used, the most perfect process of drying, vacuum treatment and impregnation will not prevent rapid deterioration of the insulation. F. M. Farmer[2] has devised a test which will indicate the relative stability of compounds. From his data it appears feasible to devise a clause for specifications which will eliminate unstable compounds. A large number of failures of the 35-kv., three-conductor cable can be directly traced to this cause aswell as a smaller number of failures occurring on 22-kv. and 13-kv., three-conductor cables.

Comparison of Quality Ratings with Accelerated Life Test Results

The relation between the quality ratings given in Table I and the results of the accelerated life tests made upon sections of the same cable is shown in Fig. 11. The variations of the individual points from the curve as drawn are no greater than might be expected from the variations in the quality of the insulation. As the accelerated life test for those cables having a life of only a few years has been found to be a fairly accurate indication of the service record of those cables, it appears that the curve in Fig. 12 verifies the results of the quality rating table, as a prediction of the service records of the cables of widely varying quality.

As the zero base weights in Table I practically correspond with specification requirements, Fig. 11 indicates that if the cable passes the specifications with a narrow margin, it will be unsatisfactory in

2. "Tests on High-Tension Cable," by F. M. Farmer, presented at Regional Meeting of A. I. E. E. at Madison, Wisconsin, on May 6-7, 1926.

service, and this indication is confirmed by experience. In the tests at the factory for cable B', the dielectric-strength tests were passed by a narrow margin, and there was a high percentage of failures in the voltage test on each section; there were several failures, both in the test after installation and in the first few months

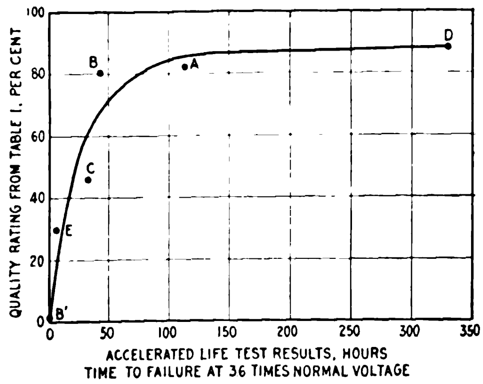

Fig. 11—Relation of Quality Ratings with Accelerated Life Test Results, for 500,000-Cir. Mil, Three-Conductor, 13-Kv. Cables

Tests which were at 46 kv. and higher were evaluated for 46 kv., which results in a maximum dielectric stress of about 72 kv. per cm.

of service. A very similar experience was had with another manufacturer. A study of the rating table clearly indicates the changes in the specifications that must be made in order to eliminate such cable by means of the factory tests.

Cable E was of slightly higher quality and gave somewhat better results in the factory tests and in

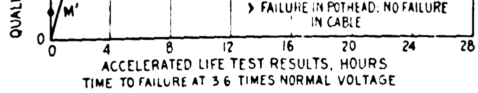

Fig. 12—Relation of Quality Ratings with Accelerated Life Test Results, for 500,000-Cir. Mil, Three-Conductor, 35-Kv. Cables

Tests were at 127 kv., which results in a maximum dielectric stress of approximately 125 kv. per cm.

service. Cable C was of still better quality, but the quality as indicated by inspection and all of the tests was very irregular. About 10 miles of this cable was installed and placed in service last fall, and one service failure, which was due to no apparent cause, occurred within two months.

Cables shown by A and B and installed last fall have had no failures in service. The quality of these cables appeared so high that lengths of about 300 ft. each were installed on 25-cycle, 20-kv. lines last fall in order to verify the quality rating as determined from the table. No failures on these test lengths have occurred to date.

Table II is a rating similar to Table I for typical examples of several different grades of 35-kv. cable which have been received to date. Fig. 12 shows the relation between these quality ratings and the accelerated life test results. Several of the cables represented have proven unsatisfactory for operation at 35-kv.; they developed the signs of ionization previously described and tests on their impregnating compounds show that they would have been rejected by Mr. Farmer's test for stability. The curve in Fig. 12 cannot be drawn with as much accuracy as the curve in Fig. 11, but Table II and Fig. 12 appear to indicate necessary changes in the specifications to insure satisfactory 35-kv., three-conductor cable.

As supplementary to the quality rating tables, the accelerated life tests appear to be a great aid, since they have revealed that even the best cables in Tables I and II still have irregularities; for instance, protruding strands of the conductor, and misplaced and broken fillers. If the tests are made on 13-kv. cable at about four times normal voltage, the results show:

1. Cable of very poor quality will usually fail within a few minutes without any visible signs of deterioration upon examination.

2. Cable of somewhat higher quality which lasts about one-half hour will develop hot spots showing irregularities in the cable, and may also develop slight tree designs and black spots.

3. Cable which will withstand this test for several hours will develop tree designs and black spots accompanied occasionally by punctures through one or more of the layers, perhaps some distance from the test failure; and the temperature of the sheath will rise about 10 to 90 deg. cent. above ambient temperature.

4. In cable of such a quality that it will withstand the test for about 50 to 100 hours, tree designs will usually be more advanced, and if the compound is unstable waxy flakes will probably be formed.

It is recognized that Table I and II are not perfect. They can never be made more accurate than the data from which they are developed, and these data will always vary in accordance with the non-uniformity of the insulation. Changes in the rating tables will be required as additional information is secured and especially to permit the tables to be properly applied to some of the new types of insulation which are now being developed. However, there appears to be no reasonable doubt as to the feasibility of using the quality rating methods outlined in this paper as a basis for modifying the specifications in order to secure cable of the desired quality.

Conclusions

1. All high-voltage tests on samples should be continued until failure occurs.
2. Long-time tests at several times normal voltage should be made on samples of the cable at the factory.
3. A test requirement should be inserted in high voltage cable specifications to prevent the use of unstable impregnating compounds.
4. The ratio of the puncture voltage obtained on the cold bent sample to the puncture voltage obtained on the straight sample appears to be an excellent test of workmanship.
5. A test is needed to indicate the minimum impregnation in a section of cable.
6. The best cable is, in general, made by the manufacturers that have the best control of their processes, as indicated by the uniformity of test results and inspection data.
7. If tests on three-conductor, high-voltage cables are of sufficient duration to develop hot spots, it has been found that (a) a majority of the cable failures will occur in hot spots and about one-third of these failures will be in the maximum hot spots; (b) a majority of the hot spots will reappear in subsequent tests on a given section of cable.
8. Higher quality of the insulation is necessary as the operating voltage increases.
9. If the compound is stable, and test and inspection data are properly correlated with operating experience, then quality rating tables can be used to predetermine with reasonable accuracy;
   a. The relative merits of several different types of insulation or lots of cable.
   b. The service record of any particular lot of cable.
10. Accelerated life tests made at suitable voltages followed by careful dissection and examinations of the insulation give consistent results which confirm the quality rating tables.

The authors gratefully acknowledge the efficient assistance they have received from C. E. Betzer, K. W. Miller, Karl Horine and L. B. Schofield in securing and correlating the information on which this paper is based.

Abridgment of

Dielectric Absorption and Theories of Dielectric Behavior

BY J. B. WHITEHEAD[1]

Fellow, A. I. E. E.

I. Introduction

Of the various component parts entering into electrical systems of all characters, the insulation is the least susceptible to exact computation and design. In few, if any cases of even simple and pure materials are the dielectric properties, resistivity, dielectric strength, specific inductive capacity, either constant or uniform; and in the cases of composite and fabricated insulations of manufacture the variations are extremely wide. As results, in all cases liberal factors of safety to cover the worst probable conditions must be allowed, resulting further in increased size and cost, and in undesirable magnitudes of other properties, such as dielectric loss and phase difference, volume and surface conductivity, circuit capacity and conductance, etc. Little if any attempt has been made to control the inherent characteristics of simple dielectrics, or to study their influence in combinations. Physicists appear to have all but forgotten the unsolved problems of dielectric behavior, or perhaps to have given them up. The control of manufactured insulation appears to be limited to heat treatment, principally for the purpose of elimination of moisture—a sufficiently important object—and to the obtaining of pure raw materials. Studies of the properties of these materials in their bearing on those of the composite final form of the insulation have not appeared in any quantity.

The Committee on Electrical Insulation of the Division of Engineering and Industrial Research of the National Research Council was formed for the purpose of pointing out the directions in which research in this field would be most profitable, and if possible to propose a plan for concerted experimental attack.

The literature describing work already done on dielectrics, from the points of view of both theory and practise, is enormous in volume. Many important data are hidden in this mass, as well as much careful and competent theoretical analysis. In order, therefore, to have as clearly as possible before it the results of all this work, the Committee has deemed it its first important duty to review the entire literature of dielectrics and insulation and to attempt to gather together the important results of the work of others into a series of reviews; and further, to draw from these

reviews conclusions as to the most promising directions for future work.

II. Historical Outline

Dielectric theory may be said to have had its origin in the work of Cavendish[2] (1773). Although looking for different values of induced charges amongst various substances, and not apparently noting the distinction between conductors and dielectrics, he nevertheless showed clearly the influence of the specific inductive capacity of the latter, and his measurements give a scale of relative values.

Faraday's elaborate studies on the exact equality between inducing and induced charges on concentric conductors, with and without dielectrics and conductors between them, led to his famous conception of a point to point transference through the medium of the influence of an electric charge, at a point, or on a conductor, at a distance. Following immediately therefrom are his well-known ideas of lines of force, tubes of induction, and dielectric polarization. Maxwell's matchless genius appreciated the importance of Faraday's work and theory, and saw the applicability of the theory of potential, as already developed by Poisson for the magnetic field. Maxwell introduced the conceptions of volume distribution of charge—the polarized molecule—as the active part of the medium demanded by Faraday, electric displacement and its magnetic effect, and built up the theory of dielectric behavior which has ever since constituted without rival, the foundation of all subsequent physical research, and of all electrical engineering applications.

The outstanding features of the theory thus briefly outlined, are the idea of dielectric polarization as developed by Faraday, and Maxwell's generalized analysis of the dielectric field. The treatment built up assumes constant values for dielectric susceptibility and specific inductive capacity, and it is interesting to note that these assumptions are common today in elementary text books, and even in more advanced treatises, in spite of our long knowledge of the limitations pertaining to such a view. The explanation is apparently found in the facts that a few substances show little or no dielectric absorption, and so constant values of susceptibility, and that with care in preparation, the error arising from dielectric absorption may be reduced for many substances to small value. In other words, it seems to be generally assumed that the phenomenon of dielectric absorption, which is not accounted for by fundamental theory, is an anomalous property of certain dielectrics, which would probably disappear if sufficient care were taken in the elimination of impurities. As a matter of fact, however, there are few substances which show no absorption, and many show it in conspicuous degree. Absorption, therefore, should rather be considered a normal property of all dielectrics, although not yet rigidly susceptible to expression in terms of fixed constants or definite functions.

Dielectric absorption made its appearance in the very earliest days of electrostatic experiment in the residual charge of the Leyden jar (1746). It is described at some length in the experiments of Benjamin Franklin (1748). It was thus well recognized by Faraday and Maxwell. In fact, as well known, Maxwell gives us the first attempt at a theoretical explanation, in terms of the normal constants of specific resistance and specific inductive capacity, as described in further detail below.

III. Dielectric Absorption and Related Phenomena

We may conveniently describe the phenomenon of dielectric absorption, and other allied properties of dielectrics in terms of the behavior of a simple parallel plate condenser.

Since it is probable that no dielectric or insulator exists which is entirely free from conductivity, it has been customary since Maxwell's classical analysis, to consider that in all dielectrics the polarization and conduction currents are superposed on each other. We may, therefore, extend our definition of a "normal" dielectric to include also the property of conductivity. Therefore, in the above case we must also recognize the presence of a conduction current, i_o, added to the charging current $i_1(t)$.

Dielectric Absorption as Observed in Experiment. Referring to our elementary condenser, the application of continuous voltage is followed by the instantaneous charging of the geometric capacity, current $i_1(t)$, a conduction current, i_o, which may or may not obey Ohm's law, and a slowly decaying "anomalous," or "absorption," or "residual" current, $i_1{}^1(t)$. If this current, $i_1{}^1(t)$, is all of "reversible" type as is usually the case in solid dielectrics, it builds up the stored or residual charge, $Q_1 = \int_0^t i_1{}^1(t) \,.\, dt$, which after the initial discharge of the geometric capacity, appears as the building up of a difference of potential between the plates if the condenser stands open, or as a slowly decaying discharge current giving a charge, $Q_2 = \int_0^t i_2(t)\, dt$, if the condenser is short-circuited. In such cases (*i. e.*, if $Q_2 = Q_1$), $i_1{}^1(t)$ will be called the "reversible absorption current." In liquid dielectrics there is also a steadily decreasing residual current $i_1{}^1(t)$, but this does not in general obey the same laws as in the case of solids, and in nearly all cases there is no corresponding discharge current $i_2{}^1(t)$. In such cases $i_1{}^1(t)$, will be called the "irreversible" absorption current.

The Reversible Absorption Current. This is the

2. A bibliography of all work referred to, and classified by subject will be found at the end of the complete paper.

absorption current commonly observed in good solid insulators, free from moisture, and there is good experimental evidence that the charge and discharge currents have the same form *i. e.*, in equation (**2**) $i_1^1(t) = i_2^1(t)$. Systematic and reliable studies of the mode of the variation of the absorption currents of charge and discharge, may be said to have begun with Kohlrausch (1854). They received a great stimulus in the experiments of Sir John Hopkinson who made extensive studies in the period 1876 to 1897, and in which he appears to have had the benefits of Maxwell's advice (Paper No. 19). Maxwell was deeply interested in the phenomena in dielectrics and treats them at great length.

Kohlrausch, Hopkinson, Giese, J. Curie, Schweidler, Shuddemagen, Jordan, Tank and others have found that the time variation of the reversible absorption current may be expressed with close accuracy by the empirical formula:

$$i_1^1(t) = a\,t^{-m} \qquad (3)$$

Others have found that the following formulas express their observations more closely:

By J. Curie, Malcles, Wagner, Steinmetz:

$$i_1^1(t) = a\,e^{-bt^n} \qquad (4)$$

By J. Curie, von Schweidler, H. A. Wilson:

$$i_1^1(t) = \frac{a}{1 + b\,t} \qquad (5)$$

By Trouton and Russ:

$$i_1^1(t) = \frac{a}{b + t} + c \qquad (6)$$

By Fleming and Dyke, Thornton:

$$i_1^1(t) = a\,e^{-bt} + c \qquad (7)$$

General Formula. With change in the value of the applied voltage, or of the thickness of the dielectric, the time rate of variation of the current is unchanged, but the values are increased in proportion to the voltage gradient (Curie, Wilson). The stationary final value of the charging current also obeys Ohm's law in most cases, and so may be considered as a normal conduction current. In a few cases, this conduction current is either absent or negligibly small, although the absorption may be quite large; *e. g.*, ebonite (Gaugain, Malclés). Generally, therefore, we may write:

$$i_1^1(t) = B\,.\,C\,E_0 = \varphi(t) \qquad (8)$$

in which B is a constant and $\varphi(t)$ a definite function for the material of the dielectric, and C the geometric capacity proportional to the area and inversely as the thickness.

Temperature has a marked influence on the absorption current. There is universal agreement, that temperature increases both the currents $i_1^1(t)$ and $i_2^1(t)$, as well as the final conduction current.

The Principle of Superposition. One of the earliest features noticed in the phenomenon of residual charge was the occasional reversal of its sign as related to the foregoing charge. Hopkinson (Papers No. 18 and 19) studied this property in glass at great length.

The following more exact statement of the principle of superposition is due to von Schweidler: After any change, ΔE, in the voltage, the actual observed current takes on an additional term, and is made up of a term representing the undisturbed variation of the original current, and a superposed current which so varies as though a voltage of the absolute value of the change in voltage, ΔE, had been applied to the uncharged condenser. If, therefore, at time $t = 0$, the voltage E_0 is applied, and then at times t_1, t_2, t_3, etc., any positive or negative changes of voltages $\Delta_1 E$, $\Delta_2 E$, $\Delta_3 E$ are applied then we have as the value of i_1^1 at any instant t.

$$i_1^1(t) = B\,C\,[\,E_0\,\varphi(t) + \Delta_1 E\,.\,\varphi(t - t_1) + \Delta_2 E\,.\,\varphi(t - t_2) + \,.\,.\,] \qquad (9)$$

Obviously the conduction current is not included in the above expression. Thus, if the final conduction current is subtracted from the charging current, it is seen that the equality of the reversible charge and discharge currents ($i_1^1 = -\,i_2^1$) is merely a special case of the principle of superposition.

Still more generally it follows, if the principle of superposition be true, that for any continuous variation of the voltage as expressed by the function $E(t)$, the reversible absorption current is given by:

$$i_1^1(t) = B\,C\,.\int_0^t \frac{d}{d\,u}\,(E(u))\,.\,\varphi(t - u)\,d\,u \qquad (10)$$

in which t is the instant at which $i_1^1(t)$ is measured and u is the elapsed time controlling the variation of E. We shall see that formula (**10**) is of great importance as a means for computing the value of dielectric loss due to alternating electric stress.

IV. Theories of Dielectric Phenomena

Theories of Dielectric Absorption. Ever since the phenomenon of residual charge was recognized there have appeared suggestions and hypotheses as to the general nature of the underlying processes. Beginning with mere suggestions in the early days, as for example, the slow penetration or "soaking in" of the charge, (readily shown to be untenable) they have increased in elaboration and complexity as further knowledge of the phenomenon has been gained. In reviewing these theories today we are presented with such pictures as a viscous yielding of the dielectric, frictional motion of molecules and electrons, infinitesimal conducting particles embedded in insulating sheaths, the free motion of electrolytic ions, dielectric hysteresis, the capillary motion of water, etc. It is impossible within a limited space to give a complete view of all these theories. It appears best, therefore, to attempt their classification into a few groups and to give one or two conspicuous examples in each group, with some attempt to outline the reasoning and evidence in support.

Most physicists offering explanations of absorption have apparently considered that the observed phenomena in anomalous dielectrics are not consistent with the fundamental equations of the electromagnetic field, and have built other equations based on new special properties of the dielectric, not embraced in the older theory. There is, however, one conspicuous instance, that of Maxwell, in which the fundamental equations are taken as a basis. We may, therefore, select two of our groups in accordance with these two views, and add a third to include those looking to present theories of the internal structure of the atom as bases for the explanation of dielectric behavior. There is also a possible fourth group as proposed by von Schweidler, in which anomalies of conductivity are invoked, but the evidence in support is not so strong as in the other groups.

Our classification of theories of dielectric absorption is then as follows:

1. Those in which the fundamental magnetic equations are retained, and the anomalies of dielectric behavior are attributed to anomalies of the structure of the dielectric medium.

2. Those in which the departures from the fundamental laws are attributed to anomalies of dielectric displacement without reference to underlying mechanism. Dielectric displacement is not proportional to field strength, but dependent on the preceding state of the dielectric.

3. Explanation of displacement and its anomalies is traced to the motion of electrons within the atom.

4. Explanations based on anomalies of conductivity, such as the free motion of ions, electrolytic dissociation, water in bulk or in capillary filaments.

Group I

Maxwell. All students of dielectric theory are familiar with Maxwell's treatment of absorption. He starts with the assumption that all dielectrics have both specific inductive capacity and conductivity as we know them in normal dielectrics, and that under electric force they function simultaneously and independently of each other. The assumption is justified by the experimental facts that conductivity may be observed in even the best insulators, and that poor insulators with very high conductivity also manifests specific inductive capacity. No further assumptions, as for example as to the origin of these properties, are necessary in Maxwell's development.

For simplicity he then assumes a dielectric as built up of a number of plain strata of different materials of thickness a_1, a_2, etc., stating that a medium formed of a conglomeration of small pieces of different materials would behave in the same way, although the case is not susceptible of exact analysis. The obvious assumption then is that every dielectric which shows absorption consists of a mixture of two or more different materials, even though under our closest examination it may appear to be homogeneous. Considering unit cross section, let X_1, X_2, etc., be the electric intensities in the several strata, f_1, f_2, etc., the displacements, k_1, k_2, etc., the reciprocals of the specific inductive capacities, r_1, r_2, etc., the specific resistances, p_1, p_2, etc., the conduction currents, and we have at any instant:

$$p_1 = \frac{X_1}{r_1} \tag{11}$$

$$f_1 = \frac{X_1}{r \pi k_1} \tag{12}$$

and

$$u = \frac{X_1}{r_1} + \frac{1}{4 \pi k_1} \frac{d X_1}{d t} \tag{13}$$

in which u is the current in the outer circuit and so in each layer. Similar equations hold for the other layers. The total e. m. f. on the condenser is the sum of X_1, X_2, X_3, etc. From equations (**13**) the X's may be evaluated as similar functions of u, in terms of the different values of r and k, and so an expression may be had for u in terms of E, *i. e.*, the charging current of the condenser as function of E, the constants of the material and the time t. Maxwell does not derive this expression, but states that if there are n layers of material having *different values of the ratio* $r : k$, the combined general equations (**13**) will form a linear differential equation of the nth order with respect to E, and the $(n - 1)$th order with respect to u, t being the independent variable. He also shows that if the ratio $r : k$ is constant for all layers the case reduces to that of a homogeneous dielectric.

Experimental evidence in favor of Maxwell's theory is very meager, and chiefly limited to indirect and broadly qualitative confirmatory observations. Cohn and Arons tested the assumption that polarization and conductivity occur independently by means of parallel condensers of different dielectrics and found good agreement. Mixtures of xylol and anilin showed a 10,000 fold variation of resistance with only a ⅓ variation of dielectric constant. Rowland and Nichols showed that in perfect samples of calcite and possibly quartz, probably the most nearly homogeneous substances available, there is no absorption. Hertz showed that benzine, a homogeneous fluid, when impure shows absorption, which disappears on purification. Arons claimed that carefully purified paraffin shows no absorption; this is disputed however by Dessau and others. Wagner finds extremely low values of power factor at 5000 cycles for ceresin and paraffin, but that for a 50 per cent-50 per cent mixture the power factor was increased several times. Muraoka by careful purification found no absorption in parraffin oil, petroleum, resin oil, turpentine and xylol. For layers of air and paraffin absorption appears. Many observers have found that the observed curves of charge and discharge currents, while not obeying the exponen-

tial law with a single term, can nevertheless be represented readily by several such terms, as called for in Maxwell's most general case. The principle of superposition as observed by Hopkinson and Curie has been shown by von Schweidler to be a necessary consequence of Maxwell's theory. However, its firmest basis is found in the fact that it introduces no new phenomena nor assumptions, but relies only on properties of matter already well known, and on fundamental electrodynamic equations. This, more than any experimental confirmation, accounts for the firm hold that this theory has on the mind of the physicist of today.

The chief disadvantage that the theory suffers is that it not only has had no quantitative nor exact experimental confirmation, but many experiments appear to offer actual contradiction. Many observers have found other expressions than the exponential for the absorption current, of whom particular mention may be made of Curie, Fleming and Dyke, and Trouton and Russ.

Wagner. Maxwell's development assumes successive layers of different dielectrics, each having different values of r and K. Many layers must be assumed to account for the results of experiment, and this leads to mathematical difficulties. The charging curve for two substances obeys the negative exponential relation to the time as already noted. Using this relation K. W. Wagner examines the curves taken on various substances, and states that only a very few exponential terms are necessary in any case to account for the curves of experiment, and moreover that the time constants of these terms group themselves more or less closely about a principle value T_0.

Group 2. Theories Based on Anomalous Displacement

As the phenomena of anomalous charge and discharge were known long before the discovery of the electron and ionic conductivity, it is natural that early theories as to their causes should have taken the form of analogies with other elastic and viscous phenomena. Thus, one of the earliest, that of Hopkinson, adopted the relations found in the elastic residual properties of ordinary materials under mechanical distortion. Electric displacement is assumed analogous to mechanical displacement. But electric displacement in the fundamental theory is proportional to the electric intensity, and not so in anomalous dielectrics, and so practically all the theories in this class assume a more or less complicated relation between the field E and the displacement D, and of such a kind that D is determined not alone by the instantaneous value of E, but also by the foregoing condition of the dielectric. Such relations exist between deformation and force in elastic media, and between induction and field strength in magnetic media.

Pellat considers the displacement as divided into two parts. The first is that of the fundamental theory:

$$D^1(t) = \frac{K}{4\pi} E(t) \tag{19}$$

the second part $D''(t)$ is assumed to obey the equation

$$\frac{d\,D''(t)}{d\,t} = \alpha\,[\,D''(\infty) - D''(t)\,]$$

$$= \alpha\left[\eta \frac{K}{4\pi} E(t) - D''(t)\right] \tag{20}$$

that is that D'' tends to a final value $D(\infty)$, proportional to E, and the rate of change of D'' is always proportional to its difference from the final value. Pellat calls D^1 the "fictitious" and D'' the "true" polarization; Schweidler, who has developed this theory further prefers the terms "normal" and "viscous" displacement.

Thus for constant E_0 and $t > 0$ we have:

$$D''(t) = \eta \frac{\overline{K}\,E_0}{4\pi}(1 - e^{-\alpha t}) \tag{21}$$

$$i_1{}^1(t) = \frac{d\,D''(t)}{d\,t} = \alpha\,\eta \frac{K}{4\pi} E_0\, e^{-\alpha t} \tag{22}$$

and the function showing the time variation of the reversible anomalous current takes the simple negative exponential form.

By integration of the above equation, we have for any type of variation of the electric force $E(t)$, remembering the principle of superposition

$$D''(t) = e^{-\alpha t} \int_0^\infty \alpha\,\eta \frac{K}{4\pi} E(u)\, e^{-\alpha u}\,.\,d\,u \tag{23}$$

$$= \alpha\,\eta \frac{K}{4\pi} \int_0^\infty E(t - \omega)\, e^{-\alpha\omega}\,.\,d\,\omega$$

and so:

$$D(t) = \frac{K}{4\pi} E(t) + \alpha\,\eta \frac{K}{4\pi} \int_\infty^t E(t - \omega)\, e^{-\alpha\omega}.\,d\,\omega \tag{24}$$

Thus, the variation of the displacement satisfies the principle of superposition, and the theory of Pellat is seen to be a special case of that of Hopkinson, in which $\varphi(\omega)$ is proportional to $e^{-\alpha\omega}$.

The simplicity of Pellat's assumption as to the variation of the displacement, and the close approximation to observations which results in the form of the anomalous charging current, make a strong appeal, in spite of the absence of all suggestion of underlying explanation. In order to supply this deficiency, von Schweidler has extended Pellat's proposal in considerable elaboration, with the aim first to bring it more nearly into accord with observation, and second to present a picture of underlying mechanism.

As regards experimental confirmation Grover, with a-c. studies of paper condensers, concluded that of several theories examined, the Pellat theory as modified by von Schweidler was the only one that could be made to give quantitative results in agreement with the obser-

vations. The quantities studied were changes in capacity and phase difference, with frequency and temperature. It is to be noted, however, that Grover did not examine Maxwell's theory as extended by Wagner, which appeared later, and which involves the same type of variation of the anomalous charging current, and an entirely analogous method of assuming a number of terms and of studying their grouping. It appears certain that an equally good agreement would have been obtained from Wagner's equations. In fact, it is safe to say the same of any theory providing for the medium a sufficient number of terms, all obeying a continually decreasing function $\varphi(t)$ of relatively simple form, but with different values of the constant terms. It appears not improbable that Wagner, not caring for von Schweidler's idea of slow period molecular oscillations, set out to picture a structure of an anomalous dielectric which would involve only the fundamental properties of specific inductive capacity and conductivity, thus adhering to Maxwell's ideas.

Group 3. Theories Based on the Structure of the Atom

Decombe in seeking an explanation of the heating of condensers, notes the remarkable and very general fact, that most thermodynamic modifications are inseparable from noticeable electric phenomena. Thus, mechanical deformations are always accompanied by both heat and electrification, (tribo-, and piezo-electric effects); capillary deformations, shock, cleavage, etc., all result in both heat and electric manifestations. Similar effects are noticeable in chemical relations, as in the thermal variations of crystals, the thermo-electric cell, the Thomson and Peltier effects, etc. He, thus, concludes that dielectric absorption and losses are also to be explained in terms of motions or deformations of electrons within the atom, and he bases an interesting and extended development of this theory on the general electron theory of Lorenz:

Separating the displacement of the ether from that of the material, as in Maxwell's theory:

$$Q = \frac{E}{4\pi} + P \qquad (25)$$

Q being the total charge, and P the "polarization." P, he assumes to be due to electron displacement and it therefore obeys Lorenz's equation:

$$E = a\frac{d^2 P}{d t^2} + b P + c \frac{d P}{d t} \qquad (26)$$

E being the electric intensity and a, b, and c constants of the reactionary forces of acceleration, elasticity, and friction respectively. He assumes further that for frequencies less than those of light the first term on the right is negligible, and so

$$E = b P + c \frac{d P}{d t} \qquad (27)$$

He shows that (27) obeys the principle of superposition, and also that it is satisfied by a value of alternating polarization computed from oscillograms taken by Hochstadter on high-tension cables. He shows further that Maxwell's equations as extended by Hess, when applied to the alternating case reduce to the same form as his own, and so by inverse reasoning, account is made for residual charge. Moreover, he shows that Pellat's arbitrary expression for the variation of the displacement follows immediately from his own equations. He shows also that under alternating e. m. f. the equations lead to a loss proportional to the square of the polarization current $\left(\frac{d P}{d t}\right)$, and a loss per period independent of the frequency, as shown experimentally by Steinmetz, Hochstadter and others. The general conclusion is that all residual effects are due to the term $c\frac{d P}{d t}$, representing a frictional force (electric) within the atom, *i. e.*, to a viscous property of the atom.

The theory is very striking in its agreements with the results of observation and in its simplicity.

Group 4. Theories Based on Anomalous Conductivity

It has often been suggested that dielectric absorption is in fact due to a varying conductivity giving rise to the motion of movable charges of "ions" within the dielectric. Experimental investigations of this idea as applied to solids are very difficult, but the irreversible anomalous current of a poorly conducting liquid offers very much wider opportunity.

Efforts have been made also to extend the same explanation (*i. e.*, ionic conduction) to the anomalous charge and discharge currents of solids, but with little success. von Schweidler has maintained that in an ionized medium the reversible anomalous current can not arise. Also that the principle of superposition cannot be explained in this way, and offers as proof the absence of residual charge in liquid dielectrics. On the other hand, Anderson and Keane have shown that the drifting of free electrons to the positive electrode will result in a space variation of charge sufficient to account for residual charge in accordance with Maxwell's theory, and have checked their conclusions with observations on sulphur. The behavior of glass is especially significant in this connection. The final conductivity of glass has undoubtedly an electrolytic character. Sodium is deposited out of glass on the electrodes, with resulting decrease of conductivity, and the latter may be maintained by providing an anode of sodium amalgam. Lithium may also be used, but apparently no other metals of the chemical group. Moreover the electrolytic action is in accordance with Faraday's laws. It must be remembered, however, that glass is not a homogenous substance and in fact

is generally considered to be a solid solution, and so of highly special character. On the other hand similar behavior has been observed in quartz, certainly not a solution, but in which small quantities of sodium and lithium are usually present. Mercury, quartz, and sodium form an electrolytic cell giving about .5 volts. H. H. Poole has shown the relation $x = e^{a+b+X}$ for the conductivity of glass, a being the thickness and X the field intensity; *i. e.*, the conductivity increases with the field strength. Gunther-Schulze sees in this an evidence of ionic conductivity and ionization by collision as in gases. Thus, while we may not be sure that glass presents a behavior typical of all anomalous dielectrics, it unquestionably is significant as showing the possibility of ionic conductivity in solids.

The Influence of Moisture. Cable paper absorbs up to 10 per cent, or even 20 per cent, by weight of moisture, rapidly at first and then more slowly. Under continuous voltage when comparatively dry (2 per cent to 3 per cent moisture) it shows a typical absorption curve in accordance with formula (3) $i_1{}^1\,(t) = a\,t^{-m}$. With increasing moisture the ordinates increase, and the curve flattens out, becoming horizontal (except for a short initial descending portion) at about 7 per cent moisture. Above this the curve of charging current with time rises gradually (Lübben). These increases are all of the nature of conduction current, for the discharge current does not take on corresponding increases, and follows equation (3) in all cases. Thus, the difference between charge and discharge currents, which usually measures the insulation resistance, increases continually with time after the application of voltage (Wagner). This indicates that the continued application of voltage causes a decrease in resistance. Moreover, the final steady value of resistance is found to depend on the voltage. So that we have the following approximate relations for the resistance r, the conductance g, and the conduction current i, in a fibrous dielectric containing moisture:

$$r = \frac{A}{\sqrt{E}};\; g = g_0\,E^m;\; i = i_0\,t^p \qquad (28)$$

E, being the voltage and A, g_0, m, i_0, p constants.

An ingenious explanation of many of the above relations has been offered by Evershed who supposes that the water is in part contained in the capillary tubes of the fibers of the material. The water is separated by air bubbles, but the walls of the tube surrounding the bubbles are wet with a thin film of water. These films constitute the principle resistance of the complete water path. Under the electric field, water is forced from the drops in the films making their walls thicker and so increasing their conductivity. In the thin state of the films they are very sensitive to slight water addition, but less so as the walls get thicker, corresponding to the observations of experiment. Evershed constructed a model containing a large number of glass capillary tubes, and studied its behavior under the microscope. He found that it gave the typical resistance, voltage, time relations found for fibrous insulation, and that the water films behaved as already stated.

D. DuBois has suggested a somewhat different mechanism for the behavior of water in dielectrics.

J. Curie showed the important part water may play in materials containing no fibers but which are porous. By maintaining porcelain at different degrees of moisture he reproduced different types of charging current curve, among them typical absorption curves as observed for dry substances. Moreover, this moist porcelain polarized up to several hundred volts, gave typical discharge curves and in fact obeyed the principle of superposition. Curie suggests in explanation the linking up of a number of internal individual electrolytic cells due to water and local conducting impurities.

V. Dielectric Behavior under Alternating Electric Force

The alternating losses in condensers were first noted by Siemens (1864), and since then they have been studied by many observers.

For a long time and even up to the present, many have assumed that the cause of these losses is to be found in some special and unknown property of dielectrics, usually called dielectric hysteresis and supposedly arising in some undiscovered molecular phenomenon, similar to that in magnetic materials. It is remarkable that this illusion should have maintained so persistent a hold, for it is easy to see that the phenomenon of absorption causes a lag of charge behind e. m. f. and so is sufficient to account for the energy component of current.

Theories Based on Absorption. *Beaulard* in 1894 and *Hess*, in 1895, gave convincing arguments against the idea of hysteresis, and *Hopkinson*, in 1897, made alternating measurements, attempting to link up absorption with the values of capacity and loss currents.

Rowland extended Maxwell's theory of absorption to the case of a sinusoidal e. m. f. and derived expressions, showing variations with the frequency, of both the capacity and the phase difference. He developed a sensitive electrodynamometer, many special types of bridge connection, and with his coworkers made numerous studies of dielectric loss, failing, however, to find close agreement with the Maxwell theory. The measurements of Curtis, in 1910, also failed to agree with this theory.

von Schweidler. Grover, in 1911, made a similar effort not only with the Maxwell-Rowland expressions, but also by extending the theories of Houllevigue, Pellat, von Schweidler, and Hopkinson, to the alternating case, and checking them with measurements on a number of condensers for frequencies up to 1000 cycles, and temperatures between 10 deg. and 35 deg. He found that von Schweidler's extension of Pellat's theory was the only one which could be made to give

quantitative results in agreement with the observations.

Wagner. Wagner has also extended his picture of the Maxwell dielectric to the alternating case in a series of papers dating from 1913. He assumes the simplest possible case of a two-layer Maxwell dielectric, and further that the conduction and displacement currents flow simultaneously, that the total currents are equal in each dielectric, and that the alternating electromotive force on the condenser is the vector sum of the e. m. f's. on the two layers. This leads at once to a complex expression for the impedance of the condenser, from which the following values of the variable dielectric constant (and so the capacity) and the variable angle of phase difference at once appear:

$$K\,\omega = K\left[1 + \frac{k}{1 + \omega^2 T^2}\right] \tag{30}$$

$$\tan\delta = k\,\frac{\omega\,T}{1 + K + \omega^2 T^2} \tag{31}$$

in which K is the specific inductive capacity corresponding to the geometric capacity, T the time constant in the exponential expression of the anomalous charging current, k a simple function of the electric constants of the two materials, and $\omega = 2\,\pi\,f$.

These two equations are in some degree in qualitative accord with the results of experiment. The former (**30**) indicates a capacity starting at a finite value and decreasing with the frequency to the geometric value at infinite frequency. This behavior is universally found in experiment. The latter equation (**31**) indicates a phase difference starting at zero, at 0 frequency, and with increasing frequency passing through a maximum and then steadily decreasing toward zero at infinite frequency. This general behavior has also been frequently observed. At times the maximum value of $\tan\delta$ may not appear, the frequency at which it occurs being determined by the constant k, and often lying outside the available range. On the other hand many other observations do not follow the comparatively simple relations indicated by (**30**) and (**31**).

Decombe has extended his electron theory of the anomalous behavior of dielectrics, already described in connection with absorption, to the explanation of alternating losses.

F. Tank has studied the Pellat-Schweidler theory for the alternating case, computing the loss as due to absorption, measuring the latter and also measuring the loss, and comparing with the computed value. The method used for computation is typical in the main of the methods used by several others (Wagner, Lahousse) and is briefly as follows: The alternating current due to an e. m. f. $E = E_0 \sin\omega\,t$, flowing in a condenser circuit may be expressed

$$i = (t) = a \sin\omega\,t + b\cos\omega\,t; \tag{33}$$

further by the principle of superposition, see formula (**10**), the anomalous charging current is:

$$i\,(t) = \beta\,C \int_{-\infty}^{t} \left(\frac{d\,E\,(u)}{d\,u}\right) \varphi\,(t - u)\,d\,u \tag{34}$$

t being the instant at which the current is considered, and u the elapsed time since the application of E. Equating the two values of $i\,(t)$, the coefficients a and b may be obtained thus showing the influence of absorption on both the capacity and the apparent conductance of the condenser.

Tank found a remarkable agreement between the measured and computed losses and currents, the per cent differences for the former in the six cases being 3.8, 4.1, − 0.4, 1.6, 13.8 and 23 per cent. He concludes from his work that the alternating losses in solid dielectrics are almost entirely accounted for by absorption, resistance loss being less than 1 per cent of the total, and no evidence of other losses.

Lahousse adopts a slightly different method of approach for computing the loss from the absorption. If E is the electric intensity, I the polarization, and k the dielectric susceptibility ($K = 1 + 4\,\pi\,k$),

$$I = k\,E\,(t) + \int_{-\infty}^{t} k\left(\frac{d}{d\,u}\,E\,(u)\right)\varphi\,(t - u)\,d\,u \tag{35}$$

For a closed cycle, the loss per cycle, w, is:

$$= \int E\,d\,I = -\int I\,d\,E \tag{36}$$

Substituting $E = E_0 \sin\omega\,t$, and introducing two new constants a and β whose values are determined by the integral in (**35**);

$$I = K\,E_0\,[\sin\omega\,t + a\sin(\omega\,t - \beta)] \tag{37}$$

This is the equation of an ellipse between I and E_0, a result independent of the form of $\varphi\,(t)$. Such ellipses have been shown experimentally by Granier. (See below).

Further, from (**36**) and (**37**)

$$w = \pi\,k\,a\,E_0^2 \sin\beta \tag{38}$$

or the loss is proportional to the square of the applied e. m. f. as often observed. Both the foregoing relations are independent of the form of $\varphi\,(t)$, which is contained in β. If $\varphi\,(t) = m\,e^{-nt}$ (Maxwell, Curie, et al), and if n is small as usually observed, the loss per cycle becomes

$$W = \frac{2\,k\,\omega\,m\,E_0^2}{\omega^2 + n^2} = \frac{2\,k\,m\,E_0^2}{\omega} \tag{39}$$

and the total loss

$$W = \frac{k\,m\,E_0^2}{\pi} \tag{40}$$

that is the loss per cycle is inversely proportional to the frequency, and the total loss independent of the frequency. As indicated below, these relations have some apparent support, but the weight of the evidence of experiment shows a loss increasing with the frequency.

J. Granier has investigated in very elegant manner the losses due to absorption alone for alternating frequencies between 0.3 and 150 cycles. He interrupts

the steady alternating excitation at different points on the cycle, and by a careful zero method obtains the total residual charge. This permits the plotting of the absorption-voltage relation for a complete cycle at each frequency. Plotted in rectangular coordinates the curves are found to be almost perfect ellipses, as called for by theoretical analysis (c. f. Lahousse above). The areas of the ellipses, representing the loss per cycle, continually decrease with increasing frequency, also in general accord with theory. The ellipses become quite flat within the range mentioned, and the study of the influence of frequency is continued up to 1500 cycles, using bridge methods. Within the entire range the total loss increases, but less than in proportion to the frequency.

VI. Comparison of Alternating Theory and Experiment

Loss-Voltage. There is almost universal theoretical agreement that the rate of loss varies as the square of the electric intensity. Many observers have studied this relation (see bibliography), and the extreme range of the exponent of the electric force appears to be from 1.3 to 2.7. However, the great mass of the evidence centers about the value 2. It is difficult to account for the values lying below 2, but those lying above permit of quite probable explanation.

Loss-Frequency. In the matter of frequency the several theoretical developments are not in entire accord. Wagner shows the loss proportional to both frequency and phase difference and as the latter first increases and then decreases with the frequency, a uniform variation in the loss is not always to be expected. Lahousse deduces a loss per cycle inversely proportional to the frequency and thus a loss per second independent of the frequency, for all but very low values. The experiments of Granier show a loss per cycle decreasing with the frequency up to 150 cycles, and a loss per second increasing only as the 0.5th and 0.6th power of the frequency, thus seeming to lend some force to Lahousse's conclusion. M. A. Frigon reports the losses in impregnated paper increasing nearly in proportion to the frequency between 20 and 60 cycles. H. J. MacLeod working on such good insulators as glass, pyrex, paraffin, cresin, mica, and with unusually careful conditions finds the losses varying as the 0.85th to 0.9th power of the frequency. Many other observers have reported losses increasing with the frequency but usually in less than direct proportion.

On the other hand, Wagner has examined the variation of the power factor with frequency over a wide range, and finds that the maximum value of the phase difference may occur for different substances in the range of 4 to 1000 cycles per second, and higher. This means that within the commercial range and far beyond, the phase difference may either increase or decrease with the frequency. This is probably the chief cause of the general confusion to be found in attempting to coordinate the results of different observers, and the reason why no simple empirical law has appeared expressing the influence of frequency on dielectric loss.

Loss-Temperature. The influence of temperature on dielectric loss is very great, the loss rapidly increasing with the temperature. But here too, it does not appear possible to expect a definite law owing to the indirect influence of temperature on other properties.

The only considerable attempt to account for the influence of temperature from a theoretical standpoint is that of Wagner. He carries it back to its effect on the time constant of the material, *i. e.*, the factor multiplying t, the time, in the exponential variation of the anomalous charging current. This enables him to bring it through into the alternating case, in its effect on phase difference, and so on the loss. He reports some remarkable general agreements with the results of observation, and his work stands out as a striking support, in the matter of temperature, of Maxwell's theory.

VII. Summary and Conclusions

1. Dielectric absorption is a conspicuous but obscure and little understood phenomenon. Its general character is well known as shown by the decay, with time, of the charging current, residual charge, etc. However, exact and definite forms of even the empirical laws are still lacking.

2. Only solids show the complete absorption phenomena of charge and discharge. Liquids often show an apparent absorption in charging but no residual phenomena. Nearly all solid dielectrics show some absorption. In some substances in a very pure state, *e. g.*, sulphur, quartz, paraffin, it is very small, if not negligible, in amount.

3. Large changes in the absorption in solids may be caused by extremely small changes in composition. Impurities and moisture in very small amounts may cause large changes in absorption.

4. The charging absorption current merges into a final steady conduction current. Both are strongly increased by increase in temperature, the absorption finally disappearing or changing into conduction.

5. The alternating losses in solid dielectrics are due almost entirely to absorption. This is shown by theoretical analysis, and confirmed by experiment. The losses due to conductivity are usually very small compared with those due to absorption, and there is no evidence of losses of other types. There is nothing to indicate a hysteresis loss of the character pertaining to magnetic materials.

6. Theories of the ultimate nature of the phenomenon of absorption are: (*a*) That it arises in the mixture of two or more dielectrics, and depends only on the known quantities, conductivity and specific inductive capacity. This is the theory of Maxwell. (*b*) That it is due to anomalous relation between electric dis-

placement and electric force, the seat of which is within the molecule or atom. Pellat, (*c*) That it may be explained by Lorenz's theory of electron motion within the structure of the atom. Décombe. (*d*) That it is due to water in capillaries or interstices in the body of the dielectric.

7. The most satisfactory theory is that of Maxwell though it is far from firmly established. The evidence is mostly indirect and it still needs quantitative proof. Probably its firmest support is found in the extension to the alternating case in which it explains a number of experimental observations. However, the theories of class (*b*) are susceptible to much the same extension.

8. From the standpoints of both theory and practise there is great need and fine opportunity for further study of the phenomenon of absorption. Thoroughgoing and careful efforts to test Maxwell's theory have been remarkably few in number. It should not be difficult to plan a comprehensive series of experiments for that purpose. Much the same may be said as to the question of the presence of electrolytic conduction in dielectrics, and its importance as a factor in explaining absorption. Moisture is difficult to eliminate completely from many dielectrics. It influences profoundly the permanent conductivity, and probably the absorption. Whether or not it is a definite factor in all absorption is a question needing, and apparently susceptible of experimental solution.

The complete paper includes an extensive bibliography on the subject of Dielectric Absorption.

Compensation for Errors of the Quadrant Electrometer in the Measurement of Power Factor

BY D. M. SIMONS[1] and WM. S. BROWN[1]
Associate, A. I. E. E. Associate, A. I. E. E.

Synopsis;—*In a previous paper, the writers developed the equations for the main errors in the quadrant electrometer for the measurement of power factor, and checked their equations experimentally, the main sources of error being the unavoidable shunting capacity to ground of the test specimens and the charging current from the electrometer needle to the quadrants. In the present paper methods of experimental compensations and elimination of these sources of error are described. Methods of compensation for capacity to ground have been presented before, and in this paper merely some additional refinements are given. The method of compensation for errors due to the charging current in the needle circuit is believed to be new; the method is described herein, the equation is derived in full, and an experimental check is given of the accuracy of the equation.*

* * * * *

I. Introduction

In a previous paper[2], the general equations of the electrometer have been given, both for the ordinary deflection method and for a new null method where the deflection is brought back to zero by inserting resistance in series with the electrometer needle. In order to save space, the previous work will not be described here, but the compensation for errors will be covered, practically as a continuation of the previous article. The following symbols will be used.

E = Voltage on the load taken as numerically equal to the transformer voltage
I = Load current or charging current of the specimen
I_h = Charging current flowing from the needle to the high quadrant
I_l = Charging current flowing from the needle to the low quadrant
r_1 = Resistance across the electrometer quadrants
r_2 = Resistance inserted in the needle circuit in the zero method, *i. e.*, the potential resistance
C_1 = Total capacity to ground of the high quadrant and all connected parts
C_2 = Capacity in the needle circuit
$\cos\phi$ = Power factor of the load
$\cos\psi$ = Power factor of the circuit in which I_h flows
n = Ratio of the transformer voltage to the needle voltage
f = Frequency
ω = $2\pi f$

In the former paper it was shown that the main source of error was due to the capacity to ground of the "high quadrant" and all connected parts, including the capacity to ground of the high quadrant itself, all connected leads, the distributed capacity of the quadrant resistance, and the capacity to ground of the low-voltage electrode of the test specimen, the last usually being a large percentage of the total. Stated differently, a large part of the reading, either by the deflection or null method, is due to the capacity to ground. It was further shown that errors would be introduced by the charging current from the needle to the high quadrant, if the load current is so small that the needle current is no longer comparatively negligible.

In the previous paper, equations were given to include

1. Both of the Standard Underground Cable Co., Pittsburgh, Pa.

2. *The Quadrant Electrometer for the Measurement of Dielectric Loss*, D. M. Simons and W. S. Brown, Trans. A. I. E. E., 1924, p. 311.

Presented at the Regional Meeting of District No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

the effect of these two sources of error as well as others. In the present paper it is proposed to give methods of experimentally compensating for these two errors, so that these terms will disappear from the general equation, and so that the final reading may be taken as if these errors did not exist. This also means a great increase in accuracy, since in general the power factor of the unknown will constitute a large part of the reading, if compensation is made. Without compensation, the power factor of the unknown load may be a very small part of the total reading, and therefore any errors may have a disproportionately great effect upon the accuracy of the power factor measured.

II. Neutralization of Capacity to Ground, C_1

Considerable errors may develop in the measurement of power factor if a large part of the reading is due to capacity to ground, C_1. For that reason, there is often a real necessity for compensating for the greater portion, if not all, of the capacity to ground. This can be done in large part by raising the potential of the shield surrounding the low-voltage electrode of the test specimen to the same potential as that of the electrode itself. For example, in the measurement of small specimens of cable, the sheath must be surrounded by a grounded shield in order to avoid stray currents. If this shield is insulated and raised to the potential of the sheath, the capacity to ground of the sheath will be ineffective.

If desired, compensation may be even more perfect than that. If the quadrants consist of tinfoil pasted on glass, other sheets of tinfoil of the same size could be pasted on the other side of each piece of glass opposite the high quadrants and insulated from the instrument. All leads to the high quadrant are normally surrounded by grounded guards, which for this purpose should be insulated. The guards of the quadrants and of the leads may now be connected to the shield surrounding the low-voltage electrode of the test specimen, and all raised to the potential of this electrode. This will compensate for all capacity to ground except the distributed capacity to ground of the quadrant resistance which is normally very small. When n equals 2, under these conditions practically all of the reading will be due to the power factor of the load.

Some experiments in compensation were performed where the load used was a short piece of cable. Fig. 1 gives the diagram of connections. The conductor of a similar piece of cable was connected to the high voltage and its sheath grounded through a resistance whose value was such that the potential drop across it was the same as that across the quadrant resistance. The sheaths of both specimens were therefore at the same potential. Compensation was then accomplished by connecting the sheath of the auxiliary specimen to the guard surrounding the load specimen.

The accuracy of compensation can be checked by a method suggested by R. W. Atkinson. A key and condenser in series are inserted between the sheath of the auxiliary specimen and the guard surrounding the load specimen. A rough adjustment of the resistance in series with the auxiliary specimen is then made and a balance or deflection taken. If compensation is correct, no change in the balance or deflection will result on closing the key. If any change does occur, the resistance in series with the auxiliary specimen can be adjusted until the reading is independent of the position of the key. If a key were used without the series condenser, the balance would probably be too sensitive, due to possible differences in power factor of the load and auxiliary specimen.

Compensation for capacity to ground may be very advantageously applied to the method outlined in Section 5 of the former paper, where two balances are required, one on a zero-loss standard S and one on the unknown X, the total capacity to ground being kept constant. This can be accomplished in the following

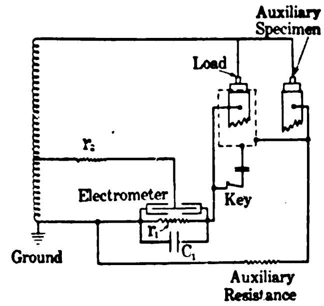

Fig. 1—Diagram of Connections for Compensation for Capacity to Ground in Quadrant Electrometer

way. Insulate the guards of both S and X and connect them to the low-voltage electrode of the auxiliary specimen. Connect S to the high voltage, and the high-voltage lead of X to the low-voltage electrode of the auxiliary specimen. Balance on S, compensation being made by means of the auxiliary resistance, series condenser and key. Then connect X to high voltage, connecting the high-voltage electrode of S to the low-voltage electrode of the auxiliary specimen. Balance on X, compensating again. A different value of auxiliary resistance, of course, will be required if the charging currents of X and S are not the same. The difference between the two $r_2 C_2 \omega$'s will give the power factor of X. The great advantage of this method lies in the fact that the capacity to ground of the instrument and leads does not have to be compensated for, and the difficulty of the shunting capacities, C_a and C_b is entirely eliminated.

III. Neutralization of the Needle Charging Current, I_h

The method used to neutralize the effect of I_h is shown in the diagram of connections, Fig. 2. The essential difference between this and the ordinary connection is that a graduated variable condenser C_3 and a variable resistance r_3, are inserted in parallel between

the low quadrant and ground. The procedure follows:

1. Connect the low-voltage electrode of the test specimen to the high quadrant, leaving the high-voltage electrode floating, a convenient quadrant resistance r_1 being inserted as usual. An equal resistance, r_3 is then inserted between the low quadrant and ground and sufficient capacity C_3 is cut in until the instrument reads zero.

2. Apply high voltage to the specimen. Inasmuch as during the previous balance the total capacity to ground of the high quadrant was higher by C_{ab} (see Section 6 of first paper), this amount of capacity must be deducted from C_3. The deflection is now brought back to zero by the potential resistance r_2 as usual (or a deflection taken), and the power factor may be obtained by the following formula:

$$\cos\phi + r_1 C_1 \omega - \frac{n-2}{2} \cdot \frac{I r_1}{E} + r_1 C_q \omega + \frac{I_h r_1}{E} = r_2 C_2 \omega \qquad (1)$$

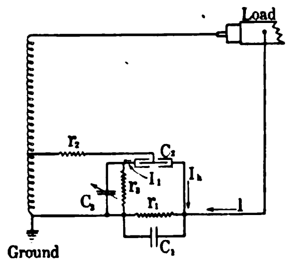

Fig. 2—Diagram of Connections for Neutralization of I_h

in which C_q *is the capacity between the high and low quadrants themselves,* and C_1 is as usual the capacity to ground of the high quadrant and all connected parts, when the low quadrant is grounded. C_1, therefore, includes C_q. C_q is in most cases absolutely negligible, especially if the quadrants are made of tinfoil on glass, and the last term on the left is usually negligible. It will therefore be seen that equation (1) is practically identical with equation (6) of Part II of the previous paper, and that all effects of the charging current I_h have been neutralized. Furthermore, the equation is entirely independent of the load current if n equals 2, and therefore, if the compensation is made, the method of balancing first on a standard condenser and then on an unknown condenser could be made regardless of the relative sizes of the two condensers, except as influenced by the changes in capacity to ground as explained in the previous paper.

Another obvious method of avoiding the effects of I_h might be briefly mentioned. If the charging current to the high quadrant is approximately equal to that of the low quadrant, and the losses are the same on both sides, all effects due to them should be removed if the ground were placed at the midpoint of the quadrant resistance, instead of grounding one set of quadrants. We believe that there is one great difficulty with this method. The low-voltage terminal of the test transformer would, of course, have to be insulated. All stray currents therefore from the high-voltage end of the transformer to ground would return to the low-voltage terminal of the transformer through the ground connection and therefore through the lower half of the quadrant resistance, thereby introducing an indeterminate and, possibly, large correction.

IV. Derivation of Equation for Neutralization of I_h

In the previous paper, an analytic method using the symbolic notation has been used. As stated in each case, the equations have also been derived geometrically from the vector diagrams with a perfect check. It appears that the present derivation is considerably simpler by the geometric method. At first thought, some of the geometry may appear too free, but it is believed to be justified because the actual vector diagram, if drawn to scale for a high-voltage measurement, especially with n equal to 1 or 2, would be so elongated that, for instance, all the vectors from the needle potential points, R, T, etc., to either quadrant are practically identical in absolute value. It is believed that practically all the substitutions about to be made are equivalent to the assumption that the angles are all so large or small that their sines or cosines, as the case may be, are equal to unity. An additional reason for confidence is that practically this same process and same assumptions completely checked the other equations derived analytically after the assumption that certain sines and cosines were equal to unity.

The vector diagram is shown in Fig. 3. $A B$ is the transformer voltage. $A N$ is the load voltage, the load current being the vector of reference. Angle $X A N$ = angle $A N M = \cos\psi$, the load power factor. B is the grounded point. The potential resistance, r_2 in Figs. 1 and 2 is connected to the transformer at any point, T.

In these first two figures r_1 and C_1 are as usual the quadrant resistance and the unavoidable shunting capacity and r_2 and C_2 are as usual in the potential circuit. It will be assumed that a resistance r_3, shunted by a capacity C_3, has been inserted between the "low quadrant" (the one usually grounded) and ground, no assumptions being made as to their present values. Let I_h and I_l be the charging currents from the needle to both the high and low quadrant respectively, and let $\cos\psi$ and $\cos\psi'$ be the power factors of these two currents respectively, as referred to the voltage between needle and quadrant.

Returning to Fig. 3, $N J'$ is the resultant voltage across the quadrants to be mentioned later. O is the midpoint of the transformer high-voltage winding, and T is the point at E/n to which r_2 is connected. $T R$ is the voltage drop across r_2, and $R D$, perpendicular to it is the effective needle voltage—assuming that

C_2 is the capacity of the instrument itself, though actually an auxiliary potential condenser is used as explained in Section 3 of the earlier paper.

If there were no capacity to ground from the high quadrant and connected parts ($C_1 = 0$) the drop across the quadrant resistance r_1 due to the load current I would be in the direction $N\,I$, parallel to $A\,X$. Due to the capacity C_1, the drop lags by an angle α and may be represented by $N\,J$. $R\,N$ is the voltage between the needle and the high quadrant, angle ψ being angle $R\,N\,H$. The direction of I_h is therefore $N\,L$, $H\,N\,L$ being a straight line. The drop across the quadrants due to I_h lags behind this by the same angle α, and therefore the drop due to this current is $N\,E$. Supposing r_3 and C_3 to still be zero, the drop across the quadrants is $N\,B$, the vector sum of $N\,J$ and $N\,E$. If resistance and capacity are now added between the low quadrant and ground, namely r_3 and C_3, the diagram changes. $R\,J'$ is the voltage between the needle and low quadrant, angle $R\,J'\,H'$ is angle ψ', and $J'\,G$ is the direction of I_l the charging current to the low quadrant. The drop across the resistance r_3 due to I_l lags behind this by an angle α'' (not equal to α, unless $r_1 = r_3$, and $C_1 = C_3$). The total quadrant voltage due to I and I_h in r_1, and I_l in r_3 is the resultant of $N\,B$ and $B\,J'$, or is equal to $N\,J'$ as stated above, making the angle α' with $N\,J$.

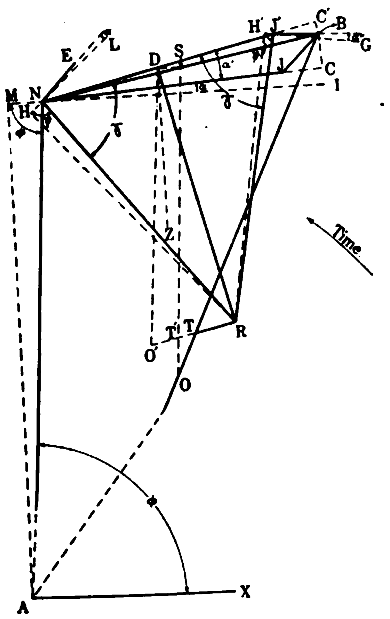

FIG. 3—VECTOR DIAGRAM FOR THE NEUTRALIZATION OF I_h

The condition of zero deflection of the instrument is that the voltage across the quadrants shall be perpendicular to the voltage from the needle to the midpoint of the quadrants, *i. e.*, $R\,D$ is the perpendicular bisector of $N\,J'$, and the proof centers about the triangle $O'\,D\,R$, including the condition mentioned above and the fact that $O'\,R$ is perpendicular to $R\,D$.

Take S as the midpoint of $N\,B$, and draw $D\,S$, which will equal one-half of $J'\,B$. Draw $O\,S$, cutting $T\,R$ produced in T'. Draw $D\,O'$ parallel to $O\,S$.

$$O\,B = E/2$$
$$T\,B = E/n$$

Therefore,

$$O\,T = O\,B - T\,B = \frac{n-2}{2\,n}\,E$$

Therefore,

$$\frac{O\,T}{O\,B} = \frac{n-2}{n} = \frac{T'\,T}{S\,B}$$

Now,

$$S\,B = N\,B/2 = \frac{(I + I_h)\,r_1}{2}$$ (if cos $B\,J\,C$ and cos $B\,N\,C$ are taken as unity)

Therefore,

$$T'\,T = \frac{n-2}{n} \cdot \frac{(I + I_h)\,r_1}{2} \qquad (2)$$

Now,

$T\,R = r_2$ times current in potential circuit

$$= \frac{E\,r_2\,C_2\,\omega}{n} \qquad (3)$$

(Since the potential voltage T to D may be confused with $T\,B$ or E/n in scalar value)

Now,

$$O'\,T' = D\,S = J'\,B/2 = \frac{I_l\,r_3}{2} \qquad (4)$$

($O'\,D$ and $O\,S$ are parallel by construction, and in the actual diagram $D\,S$ and $O'\,T'$ are practically parallel)

$$\text{Angle } O'\,D\,R = 90 \text{ deg.} - \phi + \alpha + \alpha' \qquad (5)$$

(This may be seen by drawing a line $D\,Z$ from D perpendicular to $N\,I$. $O\,S$ is parallel to $A\,N$ because O and S are the midpoints of $A\,B$ and $N\,B$ by construction, and $D\,O'$, drawn parallel to $O\,S$, is also parallel to $A\,N$. Angle $O'\,D\,Z$, therefore, $= 90$ deg. $- \phi$. $D\,R$ is perpendicular to $N\,J'$, and $D\,Z$ to $N\,I$ by construction. Therefore, angle $Z\,D\,R = \alpha + \alpha'$):

$$\text{Sin}\,O'\,D\,R \doteq \frac{O'\,R}{O'\,D} = \frac{O'\,T' + T'\,T + T\,R}{E/n} \qquad (6)$$

Substituting, (2), (3), (4), and (5) in (6), we obtain

$$\sin\,(90 - \phi + \alpha + \alpha') = \cos\phi + \sin\alpha + \sin\alpha'$$

$$= \frac{n\,I_l\,r_3}{2\,E} + \frac{n-2}{2} \cdot \frac{(I + I_h)\,r_1'}{E} + r_2\,C_2\,\omega \quad (7)$$

$\sin\alpha = r_1\,C_1\,\omega$, and therefore only $\sin\alpha'$ remains to be determined.

An auxiliary angle γ will be introduced. $\gamma =$ angle $R\,N\,J' =$ angle $N\,J'\,R$.

$$\sin\alpha' = \frac{CC'}{N\,C'} = \frac{C\,B + B\,C'}{N\,B}$$ ($N\,B = N\,C'$ if cos

$B\,N\,C'$ is unity and $C'\,B\,C$ is practically a straight line)

$$= \frac{J\,B \sin C\,J\,B + J'\,B \sin C'\,J'\,B}{N\,B}$$

But $N\,B = (I + I_h)\,r_1$, $J\,B = I_h\,r_1$, and $J'\,B = I_l\,r_3$
Angle $C\,J\,B$ = angle $C\,N\,E = 180 \text{ deg.} - \psi - \gamma + \alpha + \alpha'$
Angle $C'\,J'\,B$ = angle $R\,J'\,C'$ $-$ angle $R\,J'\,B$ = $(180 - \psi' + a'') = \psi' - \gamma - \alpha''$
Therefore,
$\sin \alpha'$ =

$$\frac{I_h\,r_1 \sin(180 - \psi - \gamma + \alpha + \alpha') + I_l\,r_3 \sin(\psi' - \gamma - \alpha'')}{(I + I_h)\,r_1} \quad (8)$$

Simplifying, dropping the sines of large angles and cosines of small ones, and rearranging terms, we obtain:

$$\sin \alpha' = \frac{I_h}{I} \cos \psi + \frac{I_h\,r_1 + I_l\,r_3}{I\,r_1} \cos \gamma$$

$$+ \frac{I_h}{I} \sin \alpha - \frac{I_l\,r_3}{I\,r_1} \cos \psi' - \frac{I_l\,r_3}{I\,r_1} \sin \alpha'' \quad (9)$$

Since ψ and ψ' are circuit constants, and $\sin \alpha = r_1\,C_1\,\omega$, and $\sin \alpha'' = r_3\,C_3\,\omega$, the only unknown is the auxiliary angle γ, which must be evaluated.

From the figure,

$$\cos \gamma = \frac{N\,D}{R\,N} = \frac{(I\,r_1 + I_h\,r_1 - I_l\,r_3)/2}{E/n} \quad (10)$$

Substituting (10) in (9), and (9) in (7) and algebraically simplifying:

$$\cos \phi + \left(1 + \frac{I_h}{I}\right) r_1\,C_1\,\omega + \frac{I_h}{I} \cos \psi$$

$$- \frac{n-2}{2} \cdot \frac{(I + I_h) r_1}{E} = r_2\,C_2\,\omega + \frac{I_l\,r_3}{I\,r_1} \cos \psi'$$

$$+ \frac{I_l\,r_3}{I\,r_1}\,r_3\,C_3\,\omega - \frac{n\,(I\,I_h\,r_1^2 + I_h^2\,r_1^2 - I_l^2\,r_3^2)}{2\,E\,I\,r_1} \quad (11)$$

This is the general equation for $\cos \phi$ in terms of the circuit constants including a resistance and capacity between the low quadrant and ground, no assumptions having been made as to their relative values.

In the actual process of neutralizing the charging current I_h as described in Section 3 of this paper, the first step was to insert r_3 between low quadrant and ground, making $r_3 = r_1$. Thus r_3 is then shunted by C_3 until the electrometer reads zero, the high-voltage electrode of the load not being connected. This means that the electrometer is measuring two equal loads, one through each set of quadrants at full voltage E/n on the needle. The losses measured on each side must, therefore, be equal. Therefore, from equation (3) of the previous article:

$$\frac{E}{n}\,I_h \cos \psi + \frac{E}{n}\,I_h\,r_1\,C_1\,\omega + \frac{I_h^2\,r_1}{2}$$

$$= \frac{E}{n}\,I_l \cos \psi' + \frac{E}{n}\,I_l\,r_1\,C_3\,\omega + \frac{I_l^2\,r_1}{2} \quad (12)$$

Dividing by $E\,I/n$:

$$\frac{I_h}{I} \cos \psi + \frac{I_h}{I}\,r_1\,C_1\,\omega$$

$$= \frac{I_l}{I} \cos \psi' + \frac{I_l}{I}\,r_1\,C_3\,\omega + \frac{n(I_l^2 - I_h^2) r_1}{2\,E\,I} \quad (13)$$

And, since $r_3 = r_1$, (11) reduces to:

$$\cos \phi + r_1\,C_1\,\omega + \frac{I_h}{I} \cos \psi + \frac{I_h}{I}\,r_1\,C_1\,\omega$$

$$- \frac{n-2}{2} \cdot \frac{(I + I_h)\,r_1}{E} = r_2\,C_2\,\omega + \frac{I_l}{I} \cos \psi'$$

$$+ \frac{I_l}{I}\,r_1\,C_3\,\omega - \frac{n\,r_1\,(I\,I_h + I_h^2 - I_l^2)}{2\,E\,I} \quad (14)$$

If (13) be subtracted from (14), the equation reduces to equation (6) of the other article, except for a practically negligible term $I_h\,r_1/E$.

If this were so, our object would be accomplished, inasmuch as all terms containing the charging currents from the needle and the power factor of these currents would be removed. It was tried out experimentally on a known load and *did not check*. Finally, the error in reasoning was discovered. It has been assumed that C_1 and C_3 are the same in equations (13) and (14) respectively and also that C_1 is as usual the total capacity to ground of the needle and all connected parts. This is true *if the capacity between the quadrants themselves is negligible*, and only in that case. If this capacity, which is an essential part of the total capacity to ground, in the usual connection, is not negligible, then raising the potential of the low quadrant will diminish the capacity to ground of the high quadrant by a certain fraction of the capacity between quadrants, which will be called C_q. The fraction of C_q which will be taken away is inversely proportional to the potential of the quadrants, or since equal resistances r_1 and r_2 are used, inversely proportional to the currents flowing in these resistances.

We will, therefore, define C_1 as the total capacity between high quadrant and ground, when the low quadrant is grounded, and C_3 as the total capacity between low quadrant and ground, when the high quadrant is grounded. C_1 will therefore be the same as in all our other equations. The values of C_1 and C_3 given in the equations of this appendix are, therefore, different from this definition as explained above, inasmuch as they are capacities when equilibrium is reached.

Equations (13) and (14), as shown below, must, therefore, be rewritten and obtain equations in which these capacities agree with their definition in the beginning of this paragraph.

(**13**) becomes

$$\frac{I_h}{I}\cos\psi + \frac{I_h}{I} r_1 \left(C_1 - \frac{I_l}{I_h} C_q \right) \omega + \frac{I_h^2 r_1}{2}$$

$$= \frac{I_l}{I}\cos\psi' + \frac{I_l}{I} r_1 \left(C_3 - \frac{I_h}{I_l} C_q \right) \omega + \frac{n\,(I_l^2 - I_h^2)}{2\,E\,I} \quad (15)$$

(**14**) becomes

$$\cos\phi + \frac{I_h}{I}\cos\psi + \left(1 + \frac{I_h}{I}\right) r_1 \left(C_1 - \frac{I_l}{I + I_h} C_q\right)\omega$$

$$- \frac{n-2}{2} \cdot \frac{(I + I_h) r_1}{E} = r_2 C_2\,\omega + \frac{I_l}{I}\cos\psi'$$

$$+ \frac{I_l}{I} r_1 \left(C_3 - \frac{I + I_h}{I_l} C_q\right)\omega - \frac{n\,r_1\,(I\,I_h + I_h^2 - I_l^2)}{2\,E\,I} \quad (16)$$

If (**15**) be subtracted from (**16**) the following is obtained

$$\cos\phi + r_1 C_1\,\omega - \frac{n-2}{2} \cdot \frac{I\,r_1}{E} + r_1 C_q\,\omega + \frac{I_h\,r_1}{E} = r_2 C_2\,\omega \quad (17)$$

This is the same as equation (**6**) of the former paper with the exception of the fourth and fifth terms, which in most instruments would be negligible, and therefore the effect of I_h has been practically neutralized by our method.

V. Experimental Proof of Neutralization of I_h

As mentioned in Section 4, it was thought at first that the method of neutralizing the effect of I_h outlined in Section 3 was practically perfect. It was tried out experimentally, a balance first being obtained on air condenser No. 1 in the usual manner, and then a balance was obtained after the procedure given in Section 3 was performed. It was expected that the balance after I_h had been neutralized would be smaller than before, primarily due to the elimination of the term $\frac{I_h}{I} r_1 C_1\,\omega$. Instead of that, however, the potential resistance required after the neutralization process had been performed was *larger*, which was puzzling. The effect of the capacity between the quadrants themselves, namely C_q was then realized, and the derivation was changed as in Section 4. Finally equation (**1**) was obtained, including the effect of the capacity between quadrants. In our instrument, the quadrants instead of being tinfoil on glass, as is often the case, were cast aluminum plates, about 3/16 in. thick, with a beading along both the outside and inside and a rib at one point, which altogether made a by no means negligible area between adjacent quadrants, the separation between quadrants being about 1/16 in. C_q was calculated on the basis of 1/16 in. separation and the effective area between quadrants, and was also calculated from the balance described by means of equation (**1**), all other quantities being known. These two values of C_q checked to within about 10 per cent, which seems quite satisfactory, inasmuch as the actual capacity between quadrants could not be calculated accurately.

It was not convenient to measure this actual capacity and the easiest method of checking equation (**1**) was actually to shunt a known condenser between quadrants and measure its capacity by a series of readings, including our procedure for neutralizing I_h.

The four following readings were taken, at 14,000 volts with half voltage on the needle, 100,000-ohms quadrant resistance, r_1 and at 60 cycles.

1. Air condenser No. 2 alone with no compensation.
2. Air condenser No. 2 alone with I_h neutralized.
3. Air condenser No. 2 with an additional condenser of capacity C_A shunted across the quadrants, no compensation.
4. Air condenser No. 2 with the *additional* condenser C_A *across the quadrants*, I_h neutralized.

By "with I_h *neutralized*" in the readings 2 and 4 above, is meant that the process outlined in Section 3 was performed, namely that the low-voltage electrode of the load was connected to the high quadrant with the high-voltage electrode point floating. A resistance of 100,000 ohms was then inserted between the low quadrant and ground, and shunting this a variable capacity was connected, which was so adjusted that the reading of the electrometer was equal to zero. This variable condenser which was graduated and calibrated, was reduced in capacity by an amount equal to the C_{ab} capacity of the load, and the high voltage was then connected to the load, and a balance performed by means of the potential resistance as usual.

Following are the values of potential resistance used, and also $r_2\,C_2\,\omega$

Reading	r_2	$r_2\,C_2\,\omega$
1	18,570 ohms	0.02950
2	19,600 "	0.03113
3	25,100 "	0.03988
4	31,600 "	0.05020

Remembering that the power factor of air condenser No. 2 is zero, the two following equations, according to equation (**8**) of the other and equation (**1**) of this paper, are obtained from the readings 1 and 2 respectively.

$$0 + \frac{I_h}{I}\cos\psi + \left(1 + \frac{I_h}{I}\right) r_1 C_1\,\omega$$

$$+ \left(1 + \frac{I_h}{I}\right)\frac{I_h\,r_1}{E} = 0.02950 \quad (18)$$

$$0 + r_1 C_1 \omega + r_1 C_q \omega + \frac{I_h r_1}{E} = 0.03113 \qquad (19)$$

Remembering that during readings 3 and 4 the total capacity to ground, as defined is equal to $C_1 + C_A$, and that the total capacity between quadrants is $C_q + C_A$, the two following equations are derived from both the equations (**8**) and (**1**) and the readings 3 and 4.

$$0 + \frac{I_h}{I} \cos \psi + \left(1 + \frac{I_h}{I}\right) r_1 (C_1 + C_A) \omega + \left(1 + \frac{I_h}{I}\right) \frac{I_h r_1}{E} = 0.03988 \qquad (20)$$

$$0 + r_1 (C_1 + C_A) \omega + r_1 (C_q + C_A) \omega + \frac{I_h r_1}{E} = 0.05020 \qquad (21)$$

Subtracting equation (**19**) from equation (**18**):

$$\frac{I_h}{I} \cos \psi + \frac{I_h}{I} r_1 C_1 \omega + \frac{I_h}{I} . \frac{I_h r_1}{I} - r_1 C_q \omega = -0.000163 \qquad (22)$$

Subtracting (**21**) from (**20**)

$$\frac{I_h}{I} \cos \psi + \frac{I_h}{I} r_1 (C_1 + C_A) \omega - r_1 (C_q + C_A) \omega + \frac{I_h}{I} . \frac{I_h r_1}{E} = -0.01032 \qquad (23)$$

Taking equation (**23**) from equation (**22**),

$$r_1 C_A \omega \left(1 - \frac{I_h}{I}\right) = 0.00969 \qquad (24)$$

Knowing that r_1 equals 100,000, I_h equals 30 microamperes, and I equals 0.568 milliamperes, and solving for C_A, the following is obtained.

$$C_A = 2.71 \times 10^{-10} \text{ farads}$$

It will be noted that C_A may also be obtained by subtracting equation (**18**) from equation (**20**), this being the ordinary method of measuring capacity as described in Section B of the previous paper. Making this subtraction

$$\left(1 + \frac{I_h}{I}\right) r_1 C_A \omega = 0.01038 \qquad (25)$$

From equation (**25**) we may calculate that $C_A = 2.61 \times 10^{-10}$ farads.

In order to check further their accuracy the authors sent the condenser C_A to an outside electrical laboratory whose measurements of the capacity were 2.53×10^{-10} farads. This check is not perfect, but it is believed to be quite satisfactory, especially in view of the difficulty with which the preliminary balance of the neutralization process with no voltage on the load was made, due to the lack of sensitivity of this instrument.

A NEW TYPE PORCELAIN PROTECTION TUBE

The choice of a proper protection tube for a thermocouple is nearly as important as the selection of the material for the couple. One of the most important properties of such a tube is low porosity to gases, since furnace gases usually attack the couple.[1] There are three general methods of attaining this low porosity: (*a*) By burning a refractory tube to a very high temperature (3000 deg. fahr.); (*b*) by adding a flux (such as feldspar) to a refractory body causing it to vitrify at a considerably lower temperature (2550 deg. to 2700 deg. fahr.); and (*c*) by coating a refractory body, which is not burned at a temperature sufficiently high to vitrify it, with an impervious glaze.

The first method is expensive and not generally practicable, and the second results in tubes which are apt to deform at operating temperatures. The third method produces tubes of satisfactory quality, is comparatively convenient, and has been adapted by this bureau to the production (by the "one-fire" method) of tubes for use in the ceramic laboratory. However, the "freezing" of the glaze to the wall of the furnace, or the ware with which it comes in contact, is a constant source of annoyance and loss of tubes by breakage. This is particularly true of laboratory work, the nature of which does not permit usually of permanent installations of tubes.

The Bureau of Standards has overcome this difficulty by the production of a "double tube" which is highly refractory, satisfactorily rigid at operating temperatures, and which is rendered impervious to gases by a coating of glaze between the double wall of the tube. The tube is formed by casting first a thin tube of the body composition, followed immediately by a cast (or coating) of the glaze, and then a third coating using the body composition to form the inner wall of the tube. When dry, this double-wall tube can be removed from the mold and burned in the usual manner.

THE FLATTEST FLAT

The United States Bureau of Standards has recently completed a flat surface which it claims has a deviation of one-ten-millionth of an inch of being perfectly flat. This is made out of quartz and will be available to American industry generally for test purposes. It is predicted that it will make for more accuracy of the development of intricate mechanical instruments employed in many manufacturing processes especially in the construction of machinery.

This "master quartz flat" will supplant the glass flats previously used by the bureau in testing micrometers and other measuring gauges used by manufacturers. With the glass flats previously used the same degree of accuracy could not be obtained because of its tendency to expand unequally due to heat.

Remote-Controlled Substations
of the New York and Queens Electric Light and Power Company

BY W. C. BLACKWOOD[1]

Member, A. I. E. E.

Synopsis.—*This paper describes a unit type of distribution substation which has been designed for a Metropolitan district. Although of much lower capacity than other stations on the same system, its cost per kv-a. is approximately the same as the larger stations. The station is unattended and all operations are controlled from a distant attended station. The cost of operation per unit of capacity is no greater than for a much larger attended station. Remote-control was adopted rather than automatic operation because of the nature of the load and territory served where service with minimum interruption is demanded.*

THE New York and Queens Electric Light and Power Company serves four wards in the Borough of Queens, New York City, covering approximately 100 sq. mi. This territory is developing very rapidly both with industrial establishments of all types and sizes and residences varying from small one-family houses to very large apartment buildings.

Energy is purchased from the United Electric Light and Power Company at 13,200 volts and 26,400 volts and is stepped down for 2300/4000 volts., four-wire, distribution in substations located in Long Island City, Flushing, Maspeth and Jamaica, the ultimate capacity of these stations being 75,000 kv-a., 40,000 kv-a., 60,000 kv-a. and 30,000 kv-a. respectively.

In 1925 it was necessary to provide additional substation capacity in the district supplied by the Jamaica Substation, and three means of accomplishing this were considered—first, to increase the size of the present substation at Jamaica; secondly, to build another similar attended station; and thirdly, to build a smaller unattended station for automatic operation or remote control, and to provide for future growth by the erection of other similar unit unattended stations.

A study of these plans indicated that the cost per kv-a. of a large attended station and a small unattended station with automatic features or remote control was approximately the same due to the greater simplicity of the smaller station and the possibility of using switches of lower interrupting capacity than would be required in a large substation where the concentration of power would be greater. It was also found possible to resort to bus regulation in the smaller station, because of the shorter distribution feeders which would be supplied by it, while in the large station it would be necessary to install regulators on the individual feeders with the attendant complication of spare feeder equipment and transfer bus.

If operators were employed the operating cost per kv-a. of the smaller station would, of course, be greater than that of a large station but, if unattended, the operating cost per kv-a., considering periodic inspections which must be made, is estimated to be less than that in the large attended station.

In considering whether an automatic or a remote-controlled substation would be built, the governing factor was the quality of service to be supplied. As demanded in a metropolitan section, it has always been the company's policy to furnish service as nearly free from interruption as possible. Also, the increasing demands upon electric service for such devices as oil-burning equipments, electric clocks, operation of radio and other uses are beginning to make the furnishing of service with 100 per cent continuity imperative. An automatic substation without supervision and control from an attended station would not give the quality of service demanded, and, in order to supply such service, it was decided that all of the operations in the substation

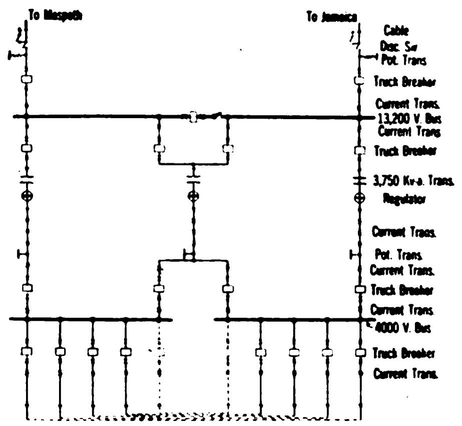

FIG. 1—ONE-LINE WIRING DIAGRAM WOODHAVEN SUBSTATION

should be under the direct and immediate control of an attendant at some point on the system. With such supervision, it was not considered necessary to install automatic features in the station, and the final decision was to build a station with all switches remote-controlled from the nearest attended station and with all operations indicated at that station.

The first substation of this type was erected in Woodhaven at a location about 2½ mi. from the Jamaica substation. Three 3750-kv-a., three-phase, oil-insulated, self-cooled transformers were installed and the rated capacity of the station is 7500 kv-a., one transformer being a spare. The station is fed by a 13,200-volt., three-phase 500,000-c.m. underground cable from the Jamaica substation and a similar cable from

1. Of the New York and Queens Electric Lt. & Power Co., Long Island City, New York.

To be presented at the Annual Convention of the A. I. E. E., White Sulphur Springs, W. Va., June 21-25, 1926.

the Maspeth substation approximately 5½ mi. away.

Referring to the wiring diagram, Fig. 1 will show that each incoming cable is connected through oil circuit breakers to a 13,200-volt bus, which is sectionalized at its mid point by an oil circuit breaker. One

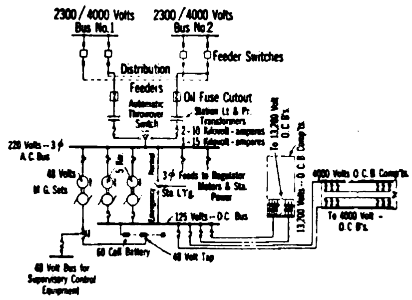

FIG. 2

transformer is connected to each section of this bus through oil circuit breakers, and the third transformer is arranged with double breakers for connection to either section of the bus. The switching connection on the 4000-volt side of the transformers is similar to

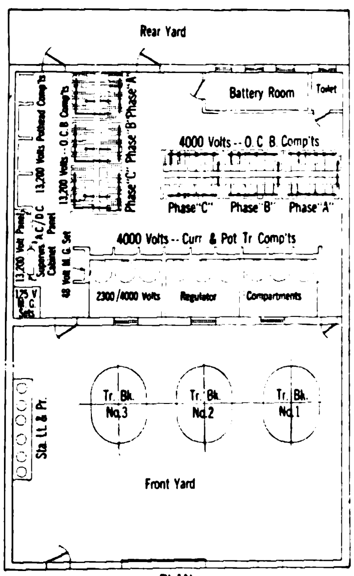

FIG. 3—PLAN OF WOODHAVEN SUBSTATION

that on the primary side, with the exception that the 4000-volt bus is operated in two sections without a tie breaker. There are four 4000-volt loop distribution feeders, the two ends of each feeder being connected to opposite sections of the 4000-volt bus. Three 135-kv-a., single-phase, automatic induction voltage regulators are connected in the secondary leads of each transformer. The distribution feeders are rated at 400 amperes for a loop feeder, although the switches on each end of the loop have a capacity of 600 amperes.

Each transformer bank is protected by differential relays and the bus sections are similarly protected so that any fault on the bus or its connections will open all breakers connected to the section in trouble. With the loop arrangement of feeders, this will cause no interruption to service.

The bus and switch structures were greatly simplified by the installation of single-phase, truck-type, oil circuit breakers, grouped according to phases both on the 13,200-volt bus and the 4000-volt bus. The transformer switches and 13,200-volt switches are controlled

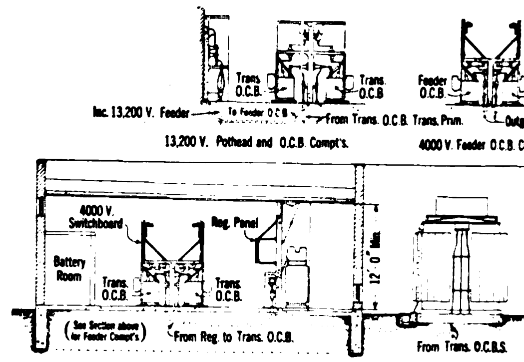

FIG. 4—SECTIONS OF WOODHAVEN SUBSTATION

as three-phase units, by electrically connecting the solenoids.

The 4000-volt feeder breakers are operated single-phase. As will be noted from the sectional drawings of the switch compartments, the grouping of all the switches on one phase makes it unnecessary to install three buses and avoids the usual connections from the

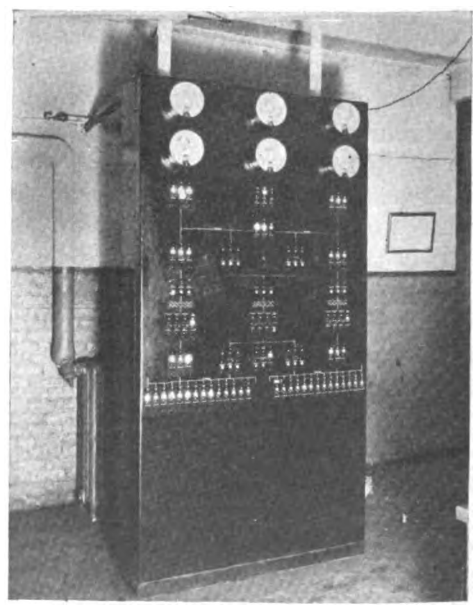

FIG. 5—PANEL OF JAMAICA SUBSTATION FOR WOODHAVEN CONTROL

bus to the switches which must, in the case of two of the phases, cross other buses if they are arranged in vertical formation.

Fig. 2 is a diagram of the control connections, in the design of which consideration was given to the fact that the station would be unattended and that therefore

continuity of the d-c. supply was essential. Two banks of station light and power transformers are fed from two 4000-volt feeders, tied to opposite bus sections. The secondaries are connected through an automatic throw-over switch to a 220-volt., three-phase bus from which two 5-kw. motor generator sets are fed. Normally,

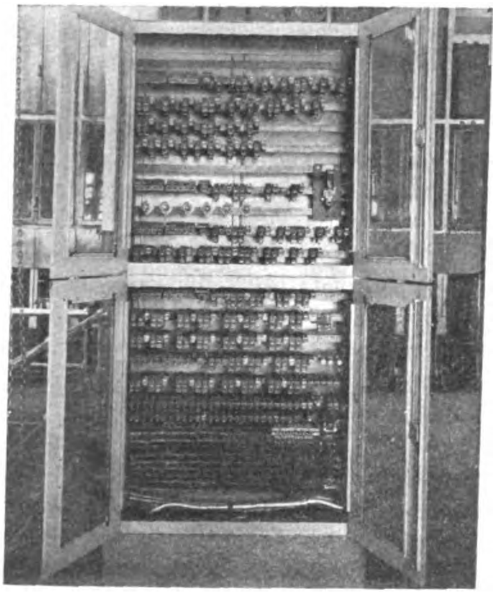

Fig. 6—Supervisory Control Relay Cabinet at Jamaica Substation for Woodhaven Control

one set is in operation, trickle-charging the battery, and relays are provided which, in case of failure of this set, will immediately place the other set in operation.

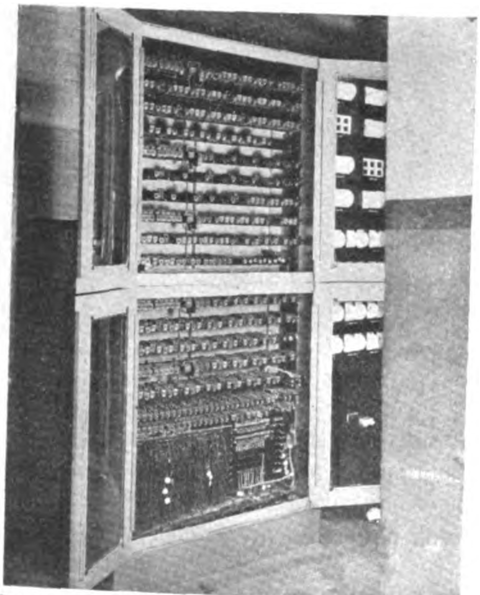

Fig. 7—Supervisory Control Relay Cabinet at Jamaica Substation for Woodhaven Control

A one-kw. motor generator is provided to supply the 48 volts, direct current, required to operate the supervisory control system. In case of failure of this set, connection is automatically made to a 48-volt tap on the station battery. The motor generator set is used for normal operation instead of the battery tap to avoid unequal discharge of the battery.

Sectionalizing switches, but no fuses, are used in the d-c. connections to the oil circuit breaker compartments and all wiring is insulated with 5/32-in. special rubber compound, so installed that grounds or short circuits are practically impossible. This plan was adopted because the blowing of a fuse in an unattended station would probably not be discovered until an attempt was made to operate a breaker and a serious interruption

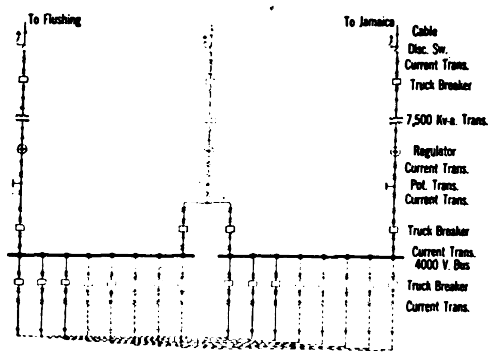

Fig. 8—One-Line Wiring Diagram—Hollis Substation

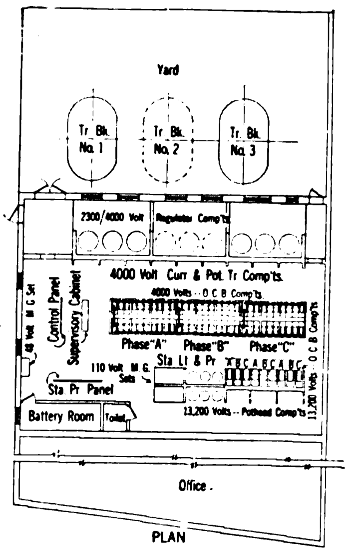

Fig. 9—Plan of Hollis Substation

might result if the d-c. supply to a trip coil was open at the time of a feeder short circuit.

All operations in the station are controlled from a panel in the Jamaica substation shown in Fig. 5. This panel is made of furniture steel and the control keys and indicating lamps are arranged in accordance with the wiring diagram of the Woodhaven station. The control is the Westinghouse Synchronous Relay Visual System, which was described in a paper by Mr. Chester Lichtenberg, presented at the Midwinter Convention in New York, February 8-11, 1926. The relay cabinets at the Jamaica and Woodhaven stations are shown in Figs. 6 and 7. The control cable, which is installed in

under ground ducts throughout, is ten pair No. 19 B&S, paper-insulated and lead-encased.

The supervisory equipment controls 21 single-pole, 13,200-volt breakers and 12 single-pole, 4000-volt breakers, in groups of three, but with single-pole indication at the Jamaica station and 24 single-pole, 4000-volt feeder switches with single-pole indication at the Jamaica station.

It is also possible to read at Jamaica, the current and voltage of each transformer in the Woodhaven station and to operate the regulators from Jamaica to equalize the voltage on the transformers when one is being cut into service.

FIG. 10—WOODHAVEN SUBSTATION 4000-VOLT OIL CIRCUIT BREAKERS AND CONTROL PANELS

Indication is given at Jamaica of high temperature in the transformer windings, ground on the d-c. control system, the operation of the battery charging motor generators and the opening of the station door.

The Woodhaven station has been in operation only a few months and therefore, no definite conclusions can be drawn as to the operation of the supervisory equipment. The installation is probably the most extensive and complicated that has yet been placed in service and there were naturally a number of difficulties encountered in starting it. These were mostly matters of relay adjustment and changes in connections which were found to give back feeds or sneak paths which caused incorrect relay operations. These have been corrected and it is believed that the reliability of operation will be at least equal to that of an attended station.

Construction of a similar station at Hollis approximately eight miles from Jamaica has been started and while the connections and arrangement are substantially the same as at Woodhaven, certain changes have been made which are considered improvements in the design.

The Hollis station will have twice the capacity, or 15,000 kv-a. supplied by two 7500-kv-a. transformers with one 7500-kv-a. spare unit. The diagram of connections is shown in Fig. 8. Each transformer will be supplied by a 13,200-volt incoming feeder with no high-tension bus. With this exception the connections are the same as at Woodhaven. There are of course eight instead of four-loop, 4000-volt feeders.

The arrangement of the bus and switch structures shown in the plan Fig. 9, is slightly different and a control board has been provided at the end of the 4000-volt bus structure on which are located the control switches for the feeder breakers which at Woodhaven are located on the panels directly above the breakers. The relays for each feeder are located on panels above the breakers as at Woodhaven but these panels have been faced in the opposite direction so that access is had from the top of the bus structure instead of from ladders in the switch aisle.

The supervisory control equipment is identical with that used at Woodhaven and the control panel will be placed alongside the Woodhaven panel in the Jamaica substation.

The growth of load in the Borough of Queens is taking place in a number of communities or centers some of which are widely separated and it is probable that the growth will be served by the erection of stations similar to those described above at or near the load centers. Supervisory control equipment, although it has pro-

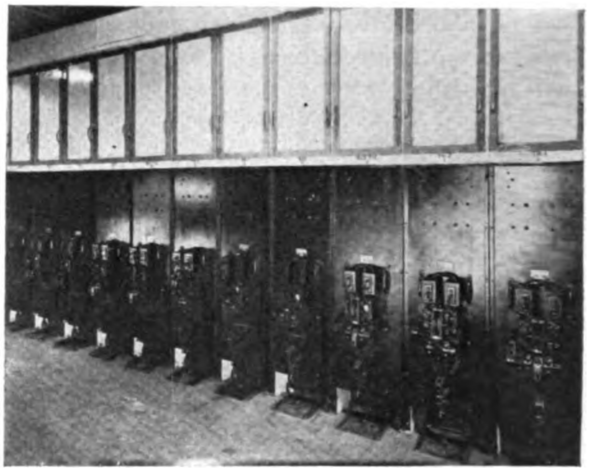

FIG. 11—WOODHAVEN SUBSTATION, 13,200-VOLT OIL CIRCUIT BREAKERS

gressed rapidly in the past few years, has been developed principally along the lines of supervision and indication of the operations of automatic stations and has not been depended upon entirely for the complete operation of stations. Much more reliable equipment is needed when the station is not arranged to operate itself automatically in case of failure of the supervisory equipment and while the equipment now available may prove to be satisfactory it will probably be found necessary to change its design in some respects to make it more rugged before the reliability of operation which is demanded in metropolitan districts, is fully realized.

Abridgment of

Refraction of Short Radio Waves in the Upper Atmosphere

BY WILLIAM G. BAKER[1]
Non-member
and
CHESTER W. RICE[2]
Associate, A. I. E. E.

***Synopsis.**—The paper shows that the striking phenomena of short-wave radio transmission (i. e., below 60 meters) can be quantitatively accounted for on a simple electron refraction theory in which the effect of the earth's magnetic field and electron collisions may be neglected as a first approximation. The distribution and number of electrons per unit volume in the upper atmosphere required on this theory to account for the meager experimental data appear to be in general accord with the values required in the explanation of the diurnal variations of the earth's magnetic field, aurorae and long-wave radio transmission.*

The paths taken by the waves from an antenna to distant points on the surface of the earth are calculated. The path calculations give a definite picture of the now familiar skip distance effects. Ideal signal intensity curves (i. e., neglecting absorption and scattering) are given, which show how the energy sent out by a transmitter is distributed over the surface of the earth. A focussing of energy just beyond the skip distance, and again just inside the point where the ray tangent to the ground at the transmitter comes back to earth is clearly shown. The reflection of waves at the surface of the earth is also considered.

The results of these calculations make it possible to estimate the most suitable wave lengths for night and day communication between any two points on the earth's surface. It is also pointed out that there will be a minimum wave length, in the vicinity of 10 meters, below which long distance communication becomes impossible. It is shown that from the point of view of long distance communication low angle radiation is most effective. The ray paths and energy flux density in the wave front of the sky waves are independent of the plane of polarization of the transmitter. The effects of polarization on the reception problem are not discussed.

I. Introduction

SHORT-wave (*i. e.*, 60 to 15 meters) transmission experiments during the past two years have definitely brought to light many peculiarities which were entirely unexpected as extrapolations from our many years of long-wave experience. Until recently any announcement of long-distance short-wave transmission was put down as an unexplained freak by the average radio man, and dismissed from his mind. As the number of such reports increased, we could no longer be content to dismiss them as freaks and were forced to abandon our preconceived notions as to what normal short-wave transmission should be, and extend our theory in such a way as to give these remarkable results a definite place in the new scheme of things.

In Fig. 1 we have attempted to summarize the available data on short-wave transmission characteristics. Most of the data are from the valuable papers by Taylor[3] and Taylor and Hulburt[4] with a few check points kindly supplied by Young.[5] We have also obtained considerable help, in drawing the smooth curves through the few scattered points, from the valuable work published by many amateurs.[6] The curves assume that 5-kw. are being supplied to an average antenna and that the practical limit of reception is reached at 10 microvolts per meter. The curves further assume full daylight or night conditions at both the transmitter and receiver in order to eliminate sunset and sunrise effects as well as peculiarities which arise when one station is in darkness and the other in daylight. This, of course, limits the diagram to practically north and south transmission; nevertheless, it may be used to estimate the general trend for other conditions.

As a typical example of the peculiarities of short-wave transmission, let us describe the experience obtained with a 5-kw., 30-meter transmitter. Here the signal rapidly descreases as we leave the transmitter and reaches the lower useful limit of 10 microvolts per meter at about 70 miles. This short range is what might be called the expected value as viewed from our long-wave experience and is represented in Fig. 1 by passing to the right of the line marked *Limit of Ground*

Wave. If we now continue to greater distances the signal remains out until we reach approximately 450 miles where th day signal unexpectedly becomes strong again. This is represented in the figure by crossing to the right of the curve marked *Minimum Range of Day Sky Wave.* Continuing to greater distances we find the signal gradually falling off in intensity, reaching the useful limit of.10 microvolts per meter in the vicinity of 4500 miles by day. This is represented in Fig. 1 by passing to the right of the curve marked *Maximum Day Range.* On a summer night the signal does not reappear after the 70 mile extinction until we are approximately 2000 miles from the transmitter, after which the signal falls off gradually to a very low value at 7500 miles.

The present explanation of the above peculiar phenomena is as follows: Assume, for simplicity, that energy is radiated equally in all directions by the transmitter. As we go away from the source. the signal strength will decrease in the usual manner due to spreading and energy absorption by the ground, with the result that the 30-meter signal practically vanishes in the vicinity of 70 miles. In other words, the ground wave component of the 30-meter signal behaves as we should expect from our long-wave experience, *i. e.*, is rapidly attenuated. The unexpected thing happens when we go out to 450 miles and find that the signal by day has reappeared. This reappearance of signal is accounted for by electronic refraction of a portion of the energy which is radiated towards the sky. A reflection theory of this effect has been proposed by Reinartz.[7] More recently a refraction theory has been developed by Taylor and Hulburt.[4] The calculations in the present paper are based on the electron theory of optical dispersion in metallic media as developed by Lorentz,[8] Drude,[9] etc. We are also greatly indebted to Eccles,[10] Larmor,[11] Appleton[12] and Nichols and Schelleng[13] who have worked out many important conclusions which follow from an application of the optical theory to various phases of the radio transmission problem.

The present calculations show that by making certain reasonable assumptions as to the number and distribution of the free electrons in the upper atmosphere the main characteristics of the relatively meager experimental results can be accounted for.

The calculated paths for rays going out from the transmitter at different angles to the horizontal show the following general characteristics: A ray starting out at a low angle will be only slightly refracted and come to earth again at a great distance from the transmitter. For higher angles the rays will return to earth progressively nearer the transmitter. Finally a critical angle is reached for which the refracted ray comes down at the nearest distance to the transmitter. For higher angles the points of return recede from the transmitter until finally a second critical angle is reached where the ray does not return to earth. but instead goes out into space and is lost.

The distance from the transmitter to the nearest point at which the refracted sky wave returns to earth has been called the "skip distance." For a given wave length the skip distance is a minimum in the middle of the day and a maximum on a winter night, the summer night value being somewhat less than the winter night skip. This variation is theoretically accounted for by a change in the height, thickness and maximum value of the electron density in the upper atmosphere.

The experimental summary given in Fig. 1 shows that the skip distance for a given time of day or night decreases with increasing wave length. This observation is in agreement with the increase in refraction on the longer wave lengths. If we neglect the effect of collisions between the electrons and gas molecules which prevent the refraction index from going to zero, we obtain a sharp upper limit in wave length above which skip distances fall to zero. For the ionization values assumed in the paper, this occurs for a wave length of 60 meters on a winter night as shown in the calculated skip distance curves of Fig. 16.

If the effect of collision frequencies were taken into account, this sharp upper limit would disappear and we would obtain skip distances on wave lengths greater than 60 meters for the assumed winter night ionization values. The effect of the earth's magnetic field will also require consideration in the vicinity of the upper limiting wave length. The experimental determination of skip distances on the longer wave lengths will be difficult owing to the masking effect of a relatively strong ground wave.

On the present theory we may expect severe fading near the transmitter under certain circumstances. For example, consider the case of 60-meter transmission on a winter night. Here a refracted or sky wave will fall inside of the ground wave limit and at a certain distance may be approximately equal in magnitude to the ground wave value. Under these conditions severe interference effects between the two waves will result. If the ground absorption is high this effect may be found quite close to the transmitter. Over salt water the effect should occur at a greater distance.

On shorter waves where the skip distance is well beyond the ground wave limit, severe fading is exp cted in the region just beyond the skip distance, where the two sky waves of approximately equal intensity overlap.

Appleton[12] and a little later Nichols and Schelleng[13] independently pointed out that the earth's magnetic

field should produce some very interesting effects on radio transmission, especially in the vicinity of 214 meters and above. It is interesting to note, in this connection, that Fig. 1 shows a marked absorption in the 214 meter region. A very interesting study of transmission phenomena in the broadcast wave length band, has recently been reported by Bown, Martin and Potter[14]. The present paper is confined to the propagation phenomena on the short-wave side of 214 meters where the effective electron restoring force due to the earth's magnetic field will cease to be important compared with the electron inertia force, and may, therefore, be neglected as a first approximation.

The subject matter contained in the body of the complete paper will be summarized here, by listing the section headings.

FOCUSING EFFECTS AT THE SKIP DISTANCE AND INSIDE OF THE TANGENT RAY

X. SUMMARY AND CONCLUSIONS

We have seen that the striking phenomena of short wave radio transmission (*i. e.*, below 60 meters) can be quantitatively accounted for on a simple electron refraction theory in which the effects of the earth's magnetic field and collisions of electrons with molecules may be neglected as a first approximation. The distribution and number of electrons per unit volume in the upper atmosphere required on this theory to account for the meager experimental data appear to be in general accord with the values required in the explanation of the diurnal variations of the earth's magnetic field, aurorae and long wave radio transmission[28].

Thus the large increase in the skip distance on a given wave length at night compared with that by day is a natural consequence of the greater ionization produced on the sunlit hemisphere by the streamers issuing from the sun. The ideal field intensity calculations given in Fig. 25 show that we may make an ample allowance for scattering and absorption and still account for the strong signals observed at great distances. The high field intensities indicated in the ideal curves of Fig. 25 at the skip distance and where the tangent ray strikes the earth are due to the focussing effect discussed in Appendix IV. The intensities at the two foci will, of course, be limited by the finite size of the source as well as by absorption and scattering.

Let us now discuss the problem of maintaining night and day communication between two points 5000 kilometers apart from the point of view of the present theory. For full winter night conditions (*i. e.*, night at both transmitter and receiver) Fig. 16 indicates that the selection of a 30-meter wave length would put the receiver right at the skip distance. Such a wave length selection would result in the arrival of two intense sky waves and consequently severe fading. Inspection of the field intensity calculations of Fig. 25 show that the field intensity produced by the ray leaving the transmitter at the higher initial angle dies out very rapidly compared with that produced by the ray having the lower initial angle. Therefore, if we pick a somewhat longer wave length than 30 meters we will receive a reasonably strong signal from one ray only and consequ ntly be less likely to find severe and rapid fading effects. We would, therefore, probably choose a wave length in the vicinity of 32 meters for winter night operation.

An alternative would be to select a wave length in the vicinity of 55 meters, with the idea of taking advantage of the focussing which occurs just inside of the distance at which the ray leaving the transmitter tangent to the ground comes back to earth. For full day conditions this wave length would be weak since 5000 kilometers is too far from the day skip distance. If we applied the above reasoning in selecting the best value for full day operation from Fig. 16 we would probably be led to select a wave length in the vicinity of 11 meters. This, however, would bring us down very close to the lower wave length limit which would mean a very weak signal. The reason for the weak signal near the low wave length limit will be readily appreciated when we remember that under these conditions we are working close to the value at which

14. Ralph Bown, De Loss K. Martin and Ralph K. Potter. *The Bell Syst. Tech. Jour.*, Vol. V, No. 1, p. 143, 1926.

28. H. J. Round, T. L. Eckersley, K. Tremellen and F. C. Lunnon. *Journ. Inst. Elec. Engg.*, Vol. 63, No. 346, p. 933, Oct. 1925.

a ray leaving the transmitter tangent to the earth's surface strikes the lower boundary of the ionized medium at the second critical angle. Under these conditions there is only a small fraction of the emitted radiation which returns to earth.

It would, therefore, be better to select a wave length in the vicinity of 15 meters and operate on the ray which is reflected from 2500 kilometers to 5000 kilometers. Under these conditions we would, of course, face the possibility of considerable fading due to interference between the weak direct ray and the reflected ray. Another method would be to use a still longer wave length, for example around 25 meters, and depend upon the reflection of the energy falling at 2500 km. which is already beginning to pile up towards the focus at 3500 km.

In this connection it is interesting to note that the reflected 25 meter signal should be much stronger at 6400 km. than at 5000 km. since the focus is in the vicinity of 3200 km. In other words, it is apparently easier to get a good day signal at 6400 km. than at 5000 km. This point of view indicates that in short wave transmission problems, there will be certain favored distances. Another point of interest is that a 28 meter wave length should give good day and night communication between two points about 6400 km. apart due to the direct ray by night and the reflection from the tangent ray focus by day.

The numerical values deduced for this example are, of course, very uncertain since the ionization constants for the upper atmosphere which are required before a set of radio transmission characteristics like Fig. 16 can be calculated were figured backward from the very meager radio data. In other words it is probably fair to say at the present time that short wave radio transmission experiments are the most direct method we have of estimating the ionization conditions in the upper atmosphere. We should not lose sight of the fact that the skip distances, etc., which depend upon the ionization conditions in the upper atmosphere are probably not constant but will vary from year to year following the 11 year sun spot period, the last minimum of which occured in 1922.

When both the transmitter and receiver are not in the sunlit or darkened hemisphere the ray paths will no longer be symmetrical about the middle point, and due allowance will have to be made for the variation of ionization conditions between the two stations. Sunset and sunrise effects will also require special treatment. It is also probable that transmission to or from the polar regions will require special study of this kind, due to the high concentration of ionization over the polar regions as compared with that over the middle belt of the earth. We can conclude in a general way that transmission from the sunlit into the darkened hemisphere will result in longer skip distances than would result if daylight extended over the whole path. For example, a ray entering the ionized medium from the sunlit side will at first meet the normal day refraction, which starts bending the ray back towards the earth and, as it moves into the darkened hemisphere, the bending by refraction will become less and less until normal night conditions exist. Thus the ray will strike the ground at a greater distance from the transmitter than it would have, if full day conditions extended over the entire path. Here the general conditions for reciprocity[29] are satisfied, so that if a ray were started back along the same path it would retrace the entire path back to the starting point.

Inspection of the day curve of Fig. 16 shows that it will be impossible to maintain communication between two distant stations on less than a 10-meter wave length. This limitation is due to the fact that the tangent ray will strike the lower boundary of the ionized medium at an angle greater than the second critical angle and will therefore not return to the earth, but be refracted out into empty space.

The precise value of this minimum wave length is, of course, not 10.6 meters, as indicated in Fig. 16, because of the meager data upon which the figure is based. There is a similar limit for full winter night conditions given as 22.5 meters in Fig. 16. Near sunset or sunrise we can, however, use a wave length less than the above full winter night limiting value, when transmitting from the dark into the light hemisphere, since the refraction is increasing in the direction of travel of the ray and may be sufficient to bend the ray back to earth.

It is now interesting to see what type of antenna directive curve will be most effective for long distance communication from the point of view of the present theory. We have seen that all of the energy which strikes the lower boundary of the ionized medium above the second critical angle is refracted out into space and is lost. The initial angle at the transmitter which corresponds to this condition is obtained from equations (80) and (97) as

$$\theta = \cos^{-1} \left\{ (1 + b/r_0) \sqrt{1 - \sigma N_0 / \omega^2} \right\}$$

which may be written for convenience as

$$\theta = \cos^{-1} \left\{ (1 + b/6300) \sqrt{1 - 9 \times 10^{-9} N_0 \lambda^2} \right\}$$

The summer day and winter night conditions on long wave lengths yield the largest useful values of the initial angle. For our assumed ionization condition we obtain $\theta = 67.8$ deg. for 40 meters on a summer day and $\theta = 64.5$ deg. for 55 meters on a winter night. For shorter wave lengths the critical values for the initial angles will be much less, as will be seen from Figs. 23 and 26. Here $\theta = 25.9$ deg. for 21 meters on a summer day and $\theta = 11.2$ deg. for 25 meters on a winter night. Thus we may conclude that on these

29. Cases where two way communication on the same wave length will not hold, due to the effect of the earth's magnetic field, or because of an electron drift velocity, have been discussed respectively by E. V. Appleton, *Nature*, p. 382, March 7, 1925, T. L. Eckersley, *Nature*, p. 466, Sept. 26, 1925.

short wave lengths all of the useful radiation is emitted between the horizontal and approximately 70 deg., and the greatest distances are reached by the low-angle radiation. We therefore conclude that for long-distance work, on short waves, maximum efficiency is obtained by low-angle radiation. This also means that nearby obstructions which cut off the low angle radiation will be detrimental to long distance working. It is therefore desirable to place the transmitter on a hill or mountain, so as to obtain an unobstructed path to the horizon in the desired direction. Raising the antenna system well above the ground will also assist by reducing ground losses and lowering the horizon.

For long distance work the plane containing the electric vector at the transmitter may make any angle whatever with respect to the ground without appreciably affecting the ray paths or energy flux density in the wave front.

In any case the earth's magnetic field will produce enough rotation of the plane of polarization to make the angle of polarization of the received ray at the surface of the ground purely a question of chance. The best type and orientation of receiving system (loop or antenna) will depend upon the direction and polarization of the arriving wave as well as upon the conductivity of the ground and height of the receiving system above the earth. Some interesting work on determining the direction of arrival of signal waves has recently been done by Appleton and Barnett[30].

The best polarization of the transmitter can therefore be considered from the point of view of ground losses, mechanical construction and such questions as nearby interference, due to the ground wave, etc.

It should be pointed out in closing that electron collisions and the effect of the earth's magnetic field will modify the shape of the skip distance curves in the vicinity of the upper asmptotic wave length. Here absorption and double refraction (*i. e.*, splitting of a ray into two components having different velocities of propagation) will require consideration in a complete theory of short wave transmission.

The above theory is based on continuous wave theory and will not apply directly to very highly damped waves. In highly damped spark transmission we are dealing with a wide band of frequencies and therefore skip distance effects, etc., will be considerably blurred. Here methods similar to those used by Eckersley[31] in his very interesting explanation of the familiar "trolley car noise" often heard by radio men, would have to be applied.

The relatively small effect of molecular refraction, due to density and temperature gradients in the lower atmosphere, discussed by Fleming[32] and Larmor[11] has been neglected.

It should also be kept in mind that only an approximate allowance has been made for the curvature of the ionized medium on the ray effect of the paths.

ACKNOWLEDGMENT

The writers owe a great deal to Mr. E. W. Kellogg for the many illuminating suggestions which he contributed during the preparation of the paper.

GERMAN-LUXEMBURG POWER SCHEME

The sites for two plants of the Ours River hydroelectric scheme, are to be such that one plant will be in Germany and the other just across the border in Luxemburg. At the point where the dam is to be built, the valley is narrow and the conditions favorable. The dam will be 106 meters high, and the average flow is 30 cubic meters per second. The impounded water will back up a distance of 28 kilometers, and flood 20 square kilometers, as well as six towns. In order to obtain more water than the Ours River itself supplies, water will be carried by pipe line from the Kyll River at Birresborn (elevation 335) to the Prum River (elevation 325) at Waxweiler, thence to the Irsen River (elevation 318) and finally to the Ours River. Water will also be drawn from the Sauer River.

Plans for Supplying Power

The new company intends to supply power only during the day and to store the water at night. During the night they may purchase cheap power and pump water back into the lake, as the day power rate is about 4½ times the night rate. A reserve supply of 200,000,000 cubic meters of water can be stored in the reservoir.

The power will be used in Luxemburg and the Rhine Provinces. Transmission lines will be built to Cologne (107 kilometers, 200,000 volts), connecting with the Goldenburg company at Duren, Trier (45 kilometers, 100,000 volts), Eteburck (50 kilometers), and Luxemburg City. When the work is completed, the company will be able to generate 400,000 kilowatt hours per day, which may be increased to 600,000. Should the demand for power increase, another plant can be erected below the present dam, giving a further capacity of 60,000 kilowatts. There are a few small power plants in the neighborhood which now produce together about one-fortieth of what the new company will be able to generate.

Current Transformers with Nickel-Iron Cores

BY THOMAS SPOONER[1]

Member, A. I. E. E.

Synopsis.—*There has been developed recently a nickel-iron alloy called hypernik which has especially low hysteresis loss and high permeability at low inductions. Due to these properties the material is particularly suitable for the cores of current transformers. A ring-type series transformer with a core of hypernik has approximately one-third of the ratio and phase-angle errors exhibited by a similar transformer having a core of ordinary silicon steel.*

The relative performance of transformers with cores of the two kinds of material are shown by test and by calculation for various burdens and ratios. The minimum ratio for which satisfactory performance can be obtained with a through-type transformer having a hypernik core is about 200 to 5.

This new material is relatively expensive but its use will undoubtedly be warranted for certain applications.

The accurate metering of power supplied at high voltages is difficult due to limitations in the performance of through-type current transformers. With a single turn for the primary the available m. m f. for low currents is very small. For a standard five-ampere secondary winding the number of secondary turns is fixed by the ratio, therefore, for a given burden inductions in the cores are high which means relatively large core losses and magnetizing currents. As the transformer ratio decreases the phase-angle errors rise very rapidly due to losses and the low permeability at low inductions for the ordinary silicon-steel core materials.

Some years ago L. W. Chubb recognized the possibility of improving the performance of current transformers by the use of certain nickel-iron alloys which have especially high permeability at low inductions.[2] Such a material has now become commercially available through the efforts of T. D. Yensen and P. H. Brace.

The purpose of this paper is to show some of the advantages which may be gained by the use of a particular nickel-iron alloy called hypernik for the cores of through-type transformers.

Current Transformer Characteristics

If the magnetic properties of the core of a current transformer and the leakage reactances of the windings are known, the ratio and the phase-angle errors for any secondary current or burden on the transformer; may be calculated quite accurately. Since this particular discussion is limited to through-type transformers, the effect of leakage reactance will be neglected since this is practically negligible for this type of transformer.[3]

In order to calculate the performance of ring-type transformers, it is necessary then to know only the watt and wattless components of magnetizing current for the particular core at the desired frequency and induction as determined by the secondary current and burden. A method of measuring the core characteristics will be discussed later.

The relation between the magnetic properties of the core and transformer performance has been shown very clearly by Agnew.[4] Fig. 1 shows the vector diagram of a current transformer supplying an inductive load.

E_2 is the secondary voltage.

I_1 and I_2 are the primary and secondary currents, respectively.

n is the ratio of the number of secondary to primary turns.

φ is the phase angle of the secondary current.

M is the magnetizing component of the core exciting current necessary to produce the flux Φ.

F is the corresponding loss component of exciting current (due to hysteresis and eddy losses in the core).

Because of the magnetizing and loss components of

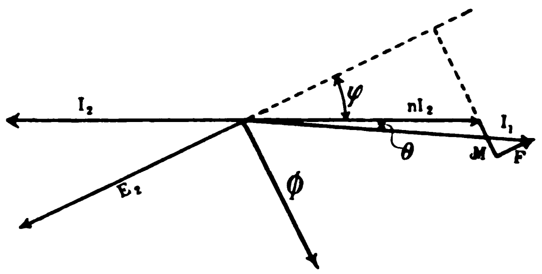

FIG. 1—VECTOR DIAGRAM OF CURRENT TRANSFORMER

the exciting current there will result (unless the exciting current is in phase opposition with the secondary current) a phase angle between the primary and secondary currents which will differ from 180 deg. by the angle θ. This is the phase-angle error of the transformer. The ratio error is proportional to the difference between I_1 and $n\,I_2$.

Agnew gives the following simplified formulas for calculating the errors in current transformers.

$$\text{Ratio } (R) = n + \frac{M \sin \varphi + F \cos \varphi}{I_2} \qquad (1)$$

2. U. S. Patent Number 1,277,384.

3. Effect of Magnetic Leakage in Current Transformers. H. W. Price, C. K. Duff.

Papers on Current Transformers. *Bull.* No. 2, Section No. 4, University of Toronto, 1921, p. 169-171.

Presented at the Regional Meeting of District No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

4. A Study of the Current Transformer with Particular Reference to Core Losses. P. G. Agnew, *Bull.* Bureau of Standards, Vol. 7, 1911, pp. 423-474.

$$\text{Tan } \theta = \frac{M \cos \varphi - F \sin \varphi}{n I_2} \quad (2)$$

Obviously if φ is 0, namely, if the burden on the secondary of the transformer is non-inductive,

$$R = n + \frac{F}{I_2} \quad (3)$$

$$\text{Tan } \theta = \frac{M}{n I_2} \quad (4)$$

In other words, for this case and a given secondary current the ratio depends only on the ratio of the secondary to primary turns and the loss in the core. The phase angle depends only on the same turn ratio and the magnetizing current or permeability of the core material.

A material is desired, therefore, which has low losses

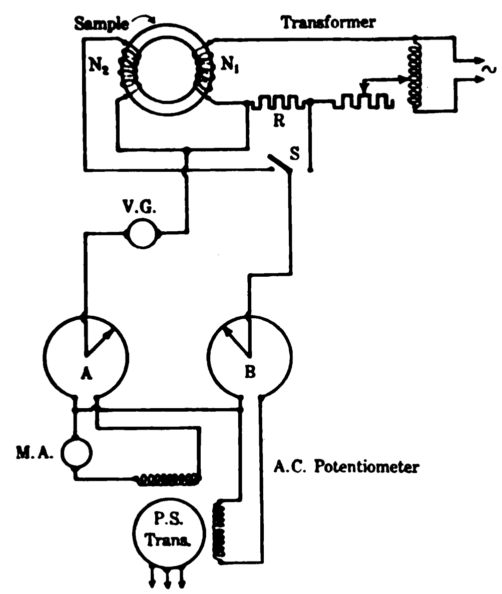

Fig. 2—Diagram of Connections for Ring Testing

and high permeability at low inductions. It is such a material which has now become available.

Determination of Magnetic Properties of Core Materials

In order to predetermine the performance of a given design of a current transformer under definite conditions of load, it is desirable to have curves for the specific kind of core material which is to be used, giving the watt and wattless components of the exciting current plotted against induction. Such data can be obtained by supplying a sample of core material with a winding or windings, applying different voltages of the desired frequency and measuring the current and watts by means of sensitive indicating instruments. For very low inductions this is rather a difficult and tedious process since the wattmeter must be very sensitive and corrections must be made for the instrument losses.

A much quicker and simpler method is to use a Tinsley-Gall, a-c. coordinate potentiometer.[5] The use of this instrument for such a purpose has been described recently.[6] The method of test is shown in Fig. 2.

The a-c. potentiometer, itself, is shown schematically. It consists of two distinct potentiometers supplied with currents which are equal in magnitude but differ 90 deg. in phase. These currents are obtained from a phase-shifting transformer having a two-phase secondary winding. Voltage balance is indicated by means of a vibration galvanometer. The sample, which is shown in ring form, is provided with primary and secondary windings N_1 and N_2. A-c. current of the desired frequency is supplied from a convenient source through a regulating transformer and a series resistance. This source is the same as that which supplies the primary of the phase-shifting transformer. The primary current I_1 is first adjusted to some convenient value and switch S is thrown to the left, thus connecting the potentiometer to the secondary winding N_2. Potentiometer B is set to O and the phase-shifting transformer and potentiometer A are then adjusted for O reading of the vibration galvanometer $V G$. When this adjustment is completed, A gives the magnitude of the secondary voltage and from it the induction in the sample can be calculated as follows, assuming a sine wave of voltage, which is nearly true for low and moderate inductions assuming approximately a sine-wave supply of current. This assumption is far from true, however, for high inductions.

$$B = \frac{E_2 \times 10^8}{A \times N_2 \times f \times 4.44} \quad (5)$$

where,

B is the induction in gausses
E_2 is the voltage induced in the secondary
A is the cross section of the specimen in sq. cm.
N_2 is the number of secondary turns
f is the frequency.

Next, S is thrown to the right connecting the potentiometer across the terminals of the shunt R. Then potentiometers A and B are adjusted for a vibration-galvanometer balance. The reading of A is now proportional to the loss component of the current in the primary and the reading of B is proportional to the wattless or magnetizing component of the current. If R equals 1 ohm, the readings of A and B are directly in amperes. This operation may be repeated for as many inductions as is desired. If more convenient a single winding only may be used on the sample, provided it has a negligible resistance.

If now the magnetizing current is multiplied by the

5. A New A-c. Potentiometer, by D. C. Gall, *Electrician*, Vol. 90, April 6, 1923, p. 360.

6. Some Applications of the A-C. Potentiometer, T. Spooner, *Journ.* Optical Society of America and Review of Scientific Instruments, March 1926, p. 217.

voltage and divided by the weight of the sample in pounds, there will result the wattless volt-amperes per pound for the material. Similarly the watt component of current gives the watts per pound. This is on the assumption that N_1 and N_2 are equal. By using a sufficiently large sample, data have been obtained by this method for a range of inductions from a few gausses to several thousand gausses, both at 25 and 60 cycles.

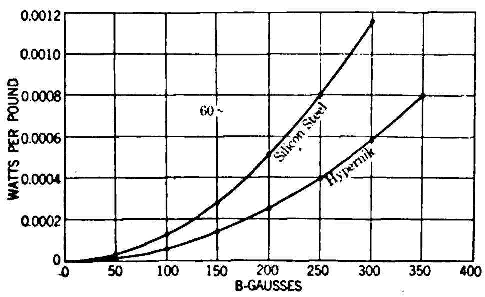

FIG. 3—CORE LOSS OF RING PUNCHINGS

Ring Dimensions = 5-7/8 in. by 3-5/8 in.

Figs. 3 to 6 show the watt and wattless volt-ampere for 60 and 25 cycles for a good grade of four per cent silicon steel as compared with a rather poor specimen of hypernik. The thickness of laminations was 0.014 in. (0.0356 cm.). These particular curves cover a rather limited range of inductions but indicate clearly the difference in the properties of the two kinds of material. The marked superiority of the hypernik is obvious. For actual design purposes it is more convenient to

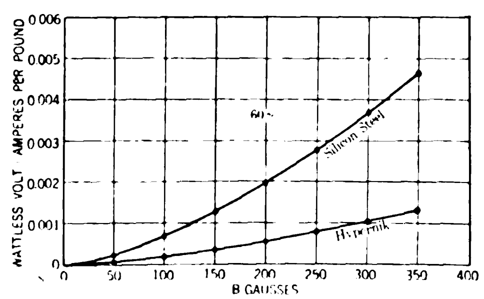

FIG. 4—MAGNETIZING CURRENT OF RING PUNCHINGS

Ring Dimensions = 5-7/8 in. by 3-5/8 in.

plot the results on double-log paper since a much larger range of inductions can be covered with less confusion of scales.

The Calculation of Performance. Using the magnetic characteristics of the material as given by such curves as shown in Figs. 3 to 6, and by using formulas (1) and (2), it is a very simple matter to predetermine the characteristics of a through-type transformer. The method will be illustrated by an example and the results compared with actual test values. The following constants apply to a transformer actually built and tested at 60 cycles.

Core Material.

Hypernik

Rings: 5⅞ in. (14.9 cm.) outside diameter; 3⅝ in. (9.2 cm.) inside diameter

Weight: 10 lb. (4.54 kilograms)

Cross section of core (density 8.3) = 14.22 sq. cm.

Secondary Windings.

Turns: (N_2) = 100

Resistance = 0.109 ohms

Burden

15 volt-amperes at 80 per cent power factor (resistance 0.480 ohms)

Inductance = 956 microhenries.

The total resistance to be considered in calculating the

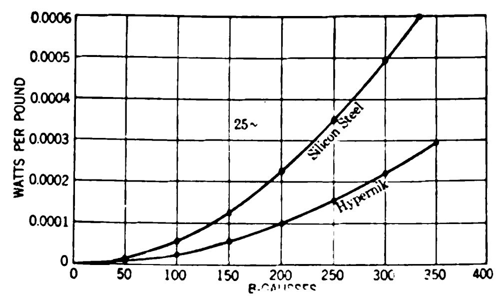

FIG. 5—CORE LOSS OF RING PUNCHINGS

Ring Dimensions = 5-7/8 in. by 3-5/8 in.

performance must include the secondary resistance of the transformer winding, therefore,

$R = 0.109 + 0.480 = 0.589$ ohm.

$X = 2\pi f\, 956 \times 10^{-6} = 0.360$ ohm.

$\sqrt{R^2 + X^2} = 0.690$ ohm

$\tan \varphi = 0.611$

$\sin \varphi = 0.521$

$\cos \varphi = 0.853$

One ampere in the secondary, therefore, corresponds

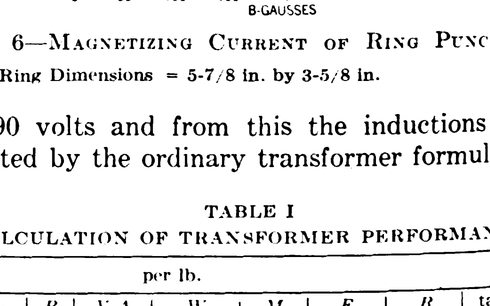

FIG. 6—MAGNETIZING CURRENT OF RING PUNCHINGS

Ring Dimensions = 5-7/8 in. by 3-5/8 in.

to 0.690 volts and from this the inductions can be calculated by the ordinary transformer formula (5).

TABLE I

CALCULATION OF TRANSFORMER PERFORMANCE

			per lb.						
I_2	E_2	B	VA	W	M	F	R	$\tan\theta$	θ
0.5	0.345	91	0.00015	0.000049	0.435	0.142	1.0069	0.00590	20′
1	0.690	182	0.00047	0.00021	0.681	0.304	1.0060	0.00422	14′
2	1.380	364	0.00140	0.00086	1.014	0.624	1.0053	0.00270	9′
3	2.070	546	0.00259	0.00200	1.250	0.966	1.0049	0.00188	7′
4	2.760	728	0.00393	0.00348	1.424	1.261	1.0045	0.00141	5′
5	3.450	910	0.00540	0.00530	1.566	1.537	1.0042	0.00107	4′

The wattless volt-amperes per pound, $V A$, and the watts per pound, W, were obtained from curves similar to those given by Figs. 3 and 4, but covering a greater range of inductions. In order to obtain M and F, it is simply necessary to multiply $V A$ and W, respectively, by $\frac{N_2 W_t}{E_2}$ where W_t is the weight of the core material in pounds. R and $\tan \theta$ are then obtained directly from formulas (**1**) and (**2**).

This detailed analysis has been followed through

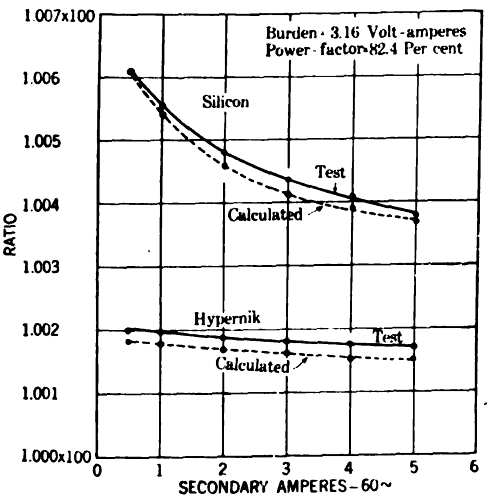

Fig. 7—500-5 Ring-Type Current Transformers
Burden = 3.16 volt-amperes
Power factor = 82.4 per cent

since it has been observed that a person not familiar with this type of calculation is very likely to make a mistake in applying the various formulas.

Check Values

Two transformers exactly alike, except that one had a silicon-steel core and the other a core of hypernik,

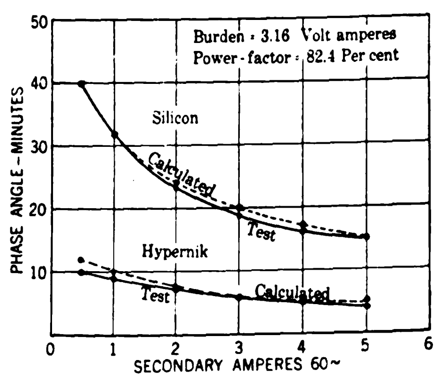

Fig. 8—500-5 Ring-Type Current Transformers
Burden = 3.16 volt-amperes
Power factor = 82.4 per cent

were constructed according to the above specifications, each core weighing 10 lb. They were sent to the Bureau of Standards for check at 60 cycles and two burdens, namely 3.16 volt-amperes and 15 volt-amperes. It may be noted that the net inductions in the two cores were slightly different although the fluxes were identical since silicon steel has a density of about 7.5 and hypernik of about 8.3.

The test and calculated results are given by Figs. 7 to 10. The checks are probably about as close as could

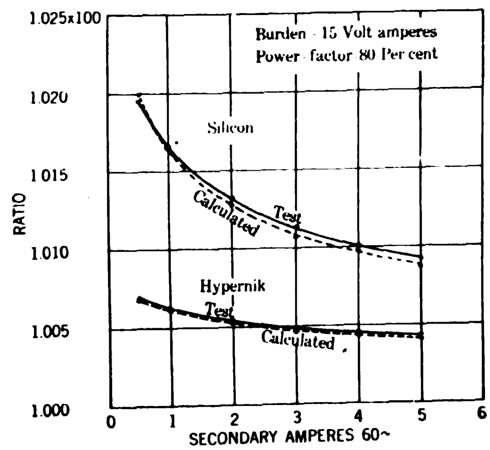

Fig. 9—500-5 Ring-Type Current Transformers
Burden = 15 volt-amperes
Power factor = 80 per cent

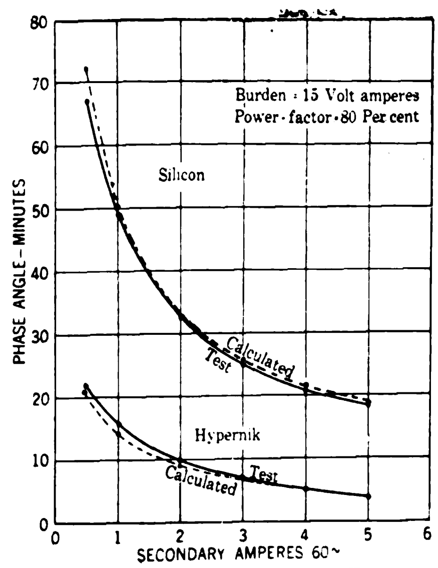

Fig. 10—500-5 Ring-Type Current Transformers
Burden = 15 volt-amperes
Power factor = 80 per cent

be expected and are in general very good. Before calculating the performance, the magnetic quality of the core material was checked on a completed transformer at two or three inductions by means of the a-c. potentiometer and where the results departed appreciably from the curves of Figs. 3 and 4, parallel curves were drawn from which the magnetic data were obtained.

Relative Performance of Transformers for Various Ranges

Having shown that it is possible to calculate the performance of this type of transformer with approximately the same accuracy as it can be tested, we are now in a position to show by calculation what can be expected

for various ranges. Figs. 11 to 15 give the comparative ratio and phase-angle curves for silicon and hypernik transformers for various ranges of secondary current from 200 to 1500 amperes, using various burdens and weights of core material. The very considerable superiority of hypernik over the silicon steel is seen for these conditions. In comparing the ratio curves it should be remembered that by means of turn compensa-

Burden = 3 volt-amperes
Power factor = 80 per cent
N_2 = 300
$Wt.$ = 2 lb.
~ = 60
R_2 = 0.05 ohms

tion the actual ratio curves may be reduced much closer to unity by this means. It will be noted, however, that this compensation will not be nearly as effective for the silicon-steel transformers since the ratio curves are not nearly as flat as for the hypernik. The phase-angle

errors will not be affected much by turn compensation. Of course, compensation for phase-angle and ratio errors can also be effected by means of parallel non-inductive or capacity shunts, but this is rather unsatisfactory since an adjustment has to be made for each burden.[2]

As an indication of the burdens which may be im-

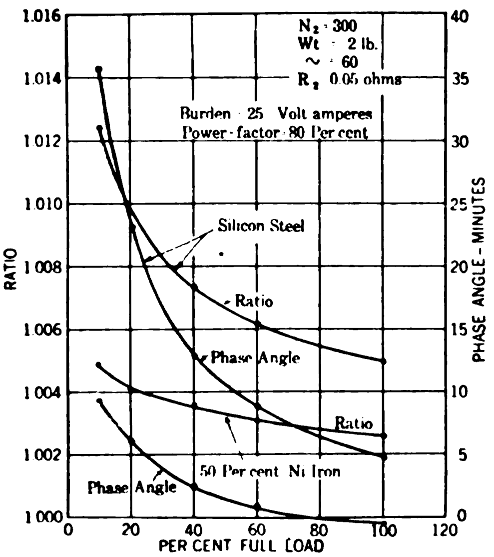

FIG. 15—1500-5 CURRENT TRANSFORMERS

R_2 = 0.05 ohms

posed on a current transformer it may be mentioned that a watthour meter requires from one to two volt-amperes at full load and a switchboard ammeter about three volt-amperes. Relays and recording instruments may take 15 volt-amperes or more.

CONCLUSIONS

A new core material for current transformers has been made available which for the same weight of core reduces the ratio (assuming no compensation) and phase-angle errors to approximately one-third of those resulting from the use of ordinary silicon steel. This material is much more expensive than silicon steel but for large installations, where considerable blocks of power need to be measured accurately, the extra cost would be insignificant as compared with the value of the improved accuracy of measurement. Where there are space limitations, if desired, a smaller amount of core material could be used giving the same performance as for the silicon steel and at approximately the same cost, but resulting in a smaller transformer.

The gain to be expected by the use of hypernik for the cores of transformers, using L-shaped punchings, would not be as great as for ring-type punchings, due to the decreased permeability resulting from the gaps. Even here, however, for the same size of transform are considerable improvement by the use of the new iron would result. The use of hypernik in through-type transformers will perhaps be the most important application since it is in this case that the transformer designer finds his chief difficulty in obtaining good performance. In this connection, however, it may be mentioned that hypernik is of no value for the cores of through-type transformers operating very heavy-burden relays since it saturates at a considerably lower induction than silicon steel. It is only at the lower inductions, namely, for meter loads, that its superiority manifests itself.

The application of this material for improving current-transformer performance is extremely simple since it involves no changes in the general transformer design and no changes in the existing meters.

MUSCLE SHOALS

The Joint Congressional Committee on Muscle Shoals has decided to recommend acceptance of the bid of the Muscle Shoals Fertilizer Company and the Muscle Shoals Power Distributing Company. The terms of the proposal submitted by the above bidders have been written into House Bill 11602 which is awaiting action in the House of Representatives. It is also understood that the acceptance of this proposal has the approval of the President and the Secretary of War.

It will be recalled that the Muscle Shoals Fertilizer Company and the Muscle Shoals Power Distributing Company represent a combination of fourteen public utility companies which have previously been interested in the use of the Muscle Shoals power.

No estimate is possible at this time as to how soon this proposed legislation will be acted upon although it is now felt no action will be taken during this session of the 69th Congress.

FEDERAL POWER COMMISSION WILL NOT INTERFERE WITH STATES RIGHTS

The case of the New York State in its control of the waters of the Niagara River, being handled before the Federal Power Commission by former Secretary of State, Charles Evans Hughes, has brought a pointed statement from the Federal Power Commission in which the members reiterated their desire not to interfere with the rights of states in the regulation or development of navigable waters in their boundaries. The project calls for the development of hydroelectric power in the Gorge below the Falls of Niagara and below the "Maid of the Mist" pool, in Niagara County, where the above named company plans to erect its power house and dam.

Mr. Hughes, in his letter, discusses at length the commission's proposed license and states that the Attorney-General of New York holds that its provisions "would constitute an invasion of authority of the State."

The Retardation Method of Loss Determination
as Applied to the Large Niagara Falls Generators

BY J. ALLEN JOHNSON[1]

Associate, A. I. E. E.

***Synopsis.**—Institute literature is apparently lacking in information regarding retardation tests. The purpose of this paper is to point out certain advantages of the method and to describe the procedure followed in testing the Niagara generators.*

The basis of the method is first given with the fundamental formula upon which it depends. Since it requires the use of the moment of inertia, or "fly-wheel effect," $W R^2$, methods of determining this value are given, and it is pointed out that it can be determined by test.

The methods of determining the speed of rotation and its rate of change are given, with a description of the devices used for automatically recording the necessary data and the method of interpreting such data. It is shown how the determination of losses over a range of speeds increases the accuracy of the determinations.

General methods of testing are described, with a connection diagram and an outline of the necessary precautions. The detail procedure for tests for different losses is given.

It is shown how this method of test furnishes data for the separation of the friction from the windage. The division of mechanical losses between generator and turbine in a specific case is also described.

The procedure in determining the electrical losses from the test data is given and some observations made regarding the apparent desirability of the further refinement of the method.

WHILE the retardation method of determining generator losses has long been known and is recognized by the Institute Standards, the Institute records are peculiarly lacking in literature on the subject, a search of the Index having failed to disclose a single paper on, or specific reference to, retardation tests. It seems rather strange that a method of testing which has found its way into the Institute Standards should have received so little attention in its literature. The explanation probably lies in the inherent simplicity of the method and the comparative rarity of its use in past times. It would appear that the method has been, and is yet, considered as a "last resort" method, to be used only when no other method is possible. It is the writer's purpose to show that the method has advantages and virtues of its own, not possessed by the usual and better known methods. It has, in the writer's opinion, never received the attention or publicity it deserves, nor been subjected to the intensive study for the perfection of its technique that is warranted by its possible accuracy and its ease of application.

The writer's attention has been focussed upon this method by the necessity of determining the conventional efficiencies of a considerable number of large water-wheel driven generators. The usual or standard method of determining generator losses is by driving the generator with a motor of known efficiency, and measuring the input to the motor under the various desired conditions. This method is usually impracticable in the case of large water-wheel generators. The most practicable and available method of making loss tests on such installations is by means of the retardation method.

The lack of repute which has apparently been attached to this method is probably due to two factors: first, that it depends upon the fly-wheel effect, $W R^2$, of the rotating parts, the determination of which has been considered to lack accuracy since it has been assumed that this value had to be calculated from the design: second, that the accurate measurement of speed and time are attended with certain difficulties which require the use of more refined methods and instruments than the usual stop-watch and indicating tachometer.

As a matter of fact, the fly-wheel effect can be determined by test; and the rate of retardation can be determined by automatic recording devices far more accurately than by the tachometer and stop-watch. In fact, the method lends itself naturally to automatic graphic recording methods, which may be made of almost any degree of accuracy desired.

This paper, therefore, will describe the procedure followed in the determination of the losses in the large generators of the Niagara Falls Power Company in an attempt to demonstrate thereby the practicability of the retardation method for the determination of the losses in such units.

The Retardation Method of Loss Test. The retardation method is based upon the fundamental law for the kinetic energy of a rotating mass, *i. e.*:

$$E = 1/2 \frac{W R^2 \omega^2}{g} \tag{1}$$

Where E is the energy.

$\frac{W}{g}$ is the mass of the rotating body

R is the radius of gyration, and

ω is the angular velocity.

If energy is added, the angular velocity or speed of rotation must increase, and if energy is abstracted, the speed must decrease. Obviously the rate at which the speed decreases must be a function of the rate of abstraction of energy, that is, of the power loss, and will be given mathematically by the first differential of

---

1. Electrical Engineer, Niagara Falls Power Company, Niagara Falls, N. Y.

Presented at the Regional Meeting of District No. 1, of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

equation (1) with respect to time. The equation for power loss then takes the form:

$$\frac{d\,E}{d\,t} = \frac{W\,R^2 \,.\, 2\,\omega\,d\,\omega}{2\,g\;\;d\,t} \qquad (2)$$

Putting $\omega = 2\,\pi\,s$ (where s is speed rev. per sec.)

$$\frac{d\,E}{d\,t} = \frac{W\,R^2}{2\,g} \,.\, 8\,\pi^2\,s \,.\, \frac{d\,s}{d\,t} \qquad (3)$$

Expressing this equation in convenient units for the purpose of generator-loss measurements, we have:

$$\text{Loss in kw.} = \frac{4\,W\,R^2\,\pi^2\,S}{32.2\,(3600 \times 33000 \times 1.34)} \cdot \frac{d\,s}{d\,t} \qquad (4)$$

Where

W is weight in pounds

R is radius of gyration in ft.

S is rev. per min.

$\frac{d\,s}{d\,t}$ is rate of retardation in rev. per min. per min.

32.2 is the acceleration of gravity in ft. per sec. per sec. and the expression in parenthesis in the denominator contains the necessary conversion factors to convert from sec. to min. and from ft-lb. per sec. to kw.

Assuming $W\,R^2$, the "fly-wheel effect," to be known it is then only necessary to determine the speed (S) and the corresponding simultaneous value of the rate of retardation $\left(\frac{d\,s}{d\,t}\right)$ to determine the corresponding instantaneous value of power loss.

For convenience it is desirable, for each generator tested, to combine all of the constants into a single constant which may be called the "retardation loss coefficient" and which may be designated by the letter D. The loss in kw. for that particular generator will then be:

$$\text{Loss in kw.} = D\,S\,\frac{d\,s}{d\,t} \qquad (5)$$

Determination of $W\,R^2$. The usual method of determining $W\,R^2$ is by calculation from design, or from design corrected by actual measurement of weights. This is a rather laborious process, but one which can, if necessary, be carried out to almost any desired degree of accuracy. The usual method is to divide the mass up into simple forms, the weights and radii of gyration of which can be easily calculated, the summation of all the parts giving the desired value for the whole. The generator manufacturers are usually required to state this value for use in the governor design, and it is therefore usually available.

The value of $W\,R^2$ can, however, be determined by means of a retardation test in connection with the direct measurement of the friction, windage and iron loss by input. In this test the generator is driven as a synchronous motor by a second generator connected to its terminals. Readings of input to the driven machine are made, also of the corresponding values of current, voltage and speed. From these readings, the values of combined friction windage and iron losses are determined. Upon the completion of these tests, the driving generator is disconnected, after raising the speed slightly, and a retardation test carried out while values of voltage, speed and rate of retardation are carefully obtained. By substituting in formula (4) above, the corresponding values of loss, speed and rate of retardation obtained from these two tests, the value of $W\,R^2$ can be readily calculated. It will usually be found, if the work is carefully performed, that the value of $W\,R^2$ so found, will check very closely with that obtained by calculation from design.

Determination of speed (S) *and rate of retardation* $\left(\frac{d\,s}{d\,t}\right)$. In the earlier tests, these quantities were measured by means of the tachometer and stop-watch, but it was found by experience that such methods are apt to give inaccurate results, particularly at the higher speeds where the speed is most rapidly changing, due to the inaccuracies of tachometers and the difficulty of accurate timing by such means.

In the later tests, automatic means were employed for recording graphically the quantities from which the speed and rate of retardation are deduced. These means comprised three devices, namely:

1. A contact-making revolution counter
2. A contact-making timer
3. A two-element chronograph

The revolution counter consisted merely in a train of gears arranged to be driven directly by the rotor of the generator under test, and with a contact-making device arranged to make contact every 10 revolutions of the generator. Any other number of revolutions per contact could, of course, be chosen if desired.

The timer used in these tests was one driven by a clock and arranged to make contact once every five sec. omitting a contact once every minute. Any other time interval within reasonable limits could likewise be provided by suitable means.

The chronograph used in these tests was a rather crude device in which the paper used for record was wrapped about a cylinder and glued to make a continuous cylinder of paper. The two pens were mounted upon the armatures of two small solenoids, so arranged that upon making circuit through the coils the pen is moved a millimeter or two, parallel to the axis of the cylinder, returning to its original position upon breaking the circuit. The cylinder is mounted upon a coarse screw thread and driven by a small synchronous motor, and advances along its axis one in. (25.4 mm.) with each revolution which it makes. In the tests to be described, the paper was driven at a speed of about three in. (75 mm.) per min. Experience has shown, however, that

a greater speed would be preferable in order to give greater accuracy in determining the generator speed.

Fig. 1 shows, *a* Timer, *b* Chronograph, and *c* Revolution Counter. The chronograph shown is not the one used in the tests herein described, but one built for future use. Fig. 2 is a reproduction of a typical chronograph record of a retardation test.

Interpretation of Chronograph Records. By drawing straight lines across the record at suitable equal time intervals, the number of revolutions occurring in each

FIG. 1—THE CHRONOGRAPH BY WHICH TESTS WERE MADE
a. Timer
b. Chronograph
c. Revolution counter

of such time intervals can be accurately measured, thereby determining the average speed of rotation during each such interval. Tabulating these and taking the differences between successive readings, gives the average rate of retardation occurring between such successive speeds. If the time intervals are taken sufficiently short the average speeds for each interval can, with sufficient accuracy, be taken as occurring at the middle of the intervals, and the corresponding values of $\frac{d\,s}{d\,t}$ as simultaneous with the times dividing the intervals. Also the speed at the division points can with sufficient accuracy be taken as the average of the preceding and succeeding intervals. In illustration, the following tabulation, Table I, is from the chronograph record of a test for friction, windage and iron loss, on a 65,000-kv-a. generator.

The curve shown in Fig. 3 is a plot of these losses against speed, from which the desired value at normal speed can be read. These results are quite consistent, and no great error can be made by this method, since errors in one direction in one or more readings must be compensated by errors in the other direction in succeeding ones. Hence, the individual errors can confidently be eliminated by plotting the results graphically.

In the usual application of the retardation method, as set forth in the handbooks, its has been customary to determine $d\,s/d\,t$, the slope of the retardation curve, at normal speed only. This has resulted in a lack of accuracy and is undoubtedly in part responsible for the lack of confidence in the method. By the method of determination here set forth, this inaccuracy is eliminated by the device of using the entire curve to eliminate the errors in individual points, which is particularly applicable in this case since the curve as a whole cannot depart far from the truth.

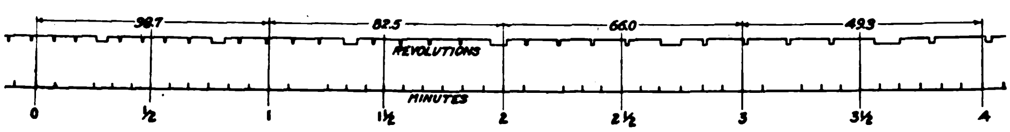

FIG. 2—CHRONOGRAPHIC RECORD OF RETARDATION TEST FOR FRICTION, WINDAGE AND LOAD LOSSES ON 65,000-KV-A. GENERATOR

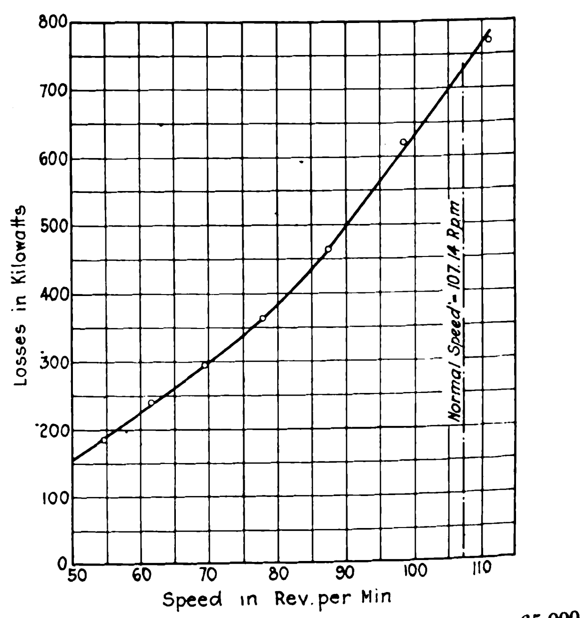

FIG. 3—FRICTION, WINDAGE AND IRON LOSSES OF 65,000-KV-A. UNIT WITH EXCITATION CORRESPONDING TO 11,100 VOLTS AT 107.14 REV. PER MIN.

This same test will illustrate the method, mentioned above, of determining by test the value of $W R^2$. The same machine showed friction, windage and iron losses as measured by input, at normal speed of 107.14 rev. per min., and at the same voltage as obtained at normal speed during the retardation test of 695 kw., see Fig. 4. The value of $d s/d t$ at the same speed, from the retardation test is 12.99 rev. per min. per min. Therefore, from equation 4:

$$W R^2 = \frac{695 \times 36000 \times 33000 \times 1.34 \times 32.2}{4 \times 9.87 \times 107.14 \times 12.99}$$

$$= 64{,}700{,}000$$

$W R^2$ as calculated from design	68,255,000
Difference	3,555,000

or about 5 per cent. Much closer agreement than this is usually found, in many cases the test value checking exactly with the calculated, see Fig. 6. However, in a machine of this size, even an error of this magnitude could only affect the efficiency determination by less than one-tenth of one per cent.

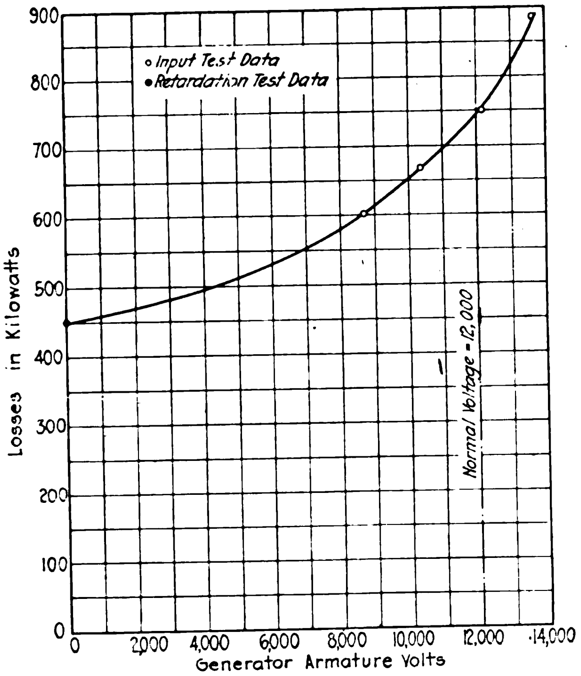

FIG. 4—FRICTION, WINDAGE AND IRON LOSSES OF 65,000-KV-A. UNIT—NORMAL SPEED 107.14 REV. PER MIN.

General Methods of Test. Before starting a series of retardation tests, it is necessary that the unit be properly prepared. It is desirable that the generator be separated from the turbine, if possible. In horizontal-shaft units and in vertical-shaft units where the generator has a lower guide bearing, the coupling can usually be separated and the generator operated without the turbine. In vertical units where the generator has no lower guide bearing, or where, for some other reason, the coupling cannot be separated, it becomes necessary to permit the turbine to rotate with the generator. This introduces losses which cannot be charged to the generator and considerable judgment and ingenuity is then required to apportion the observed losses between generator and turbine.

When it is necessary to include the turbine rotor with the generator, precaution should be taken to guard against injury to the turbine by overheating bearings or glands or runner rim by possible rubbing at the latter point, due to too close clearance. A small amount of water can usually be supplied to such points to keep them cool. In such a case, however, it is essential that conditions of water flow, etc., be kept constant during the tests in order to eliminate any variable factors from this source.

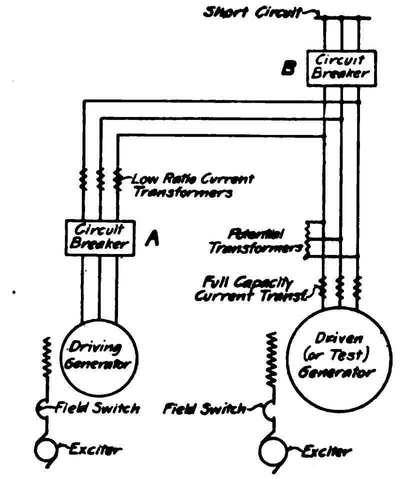

FIG. 5—DIAGRAM OF CONNECTIONS FOR RETARDATION TESTS

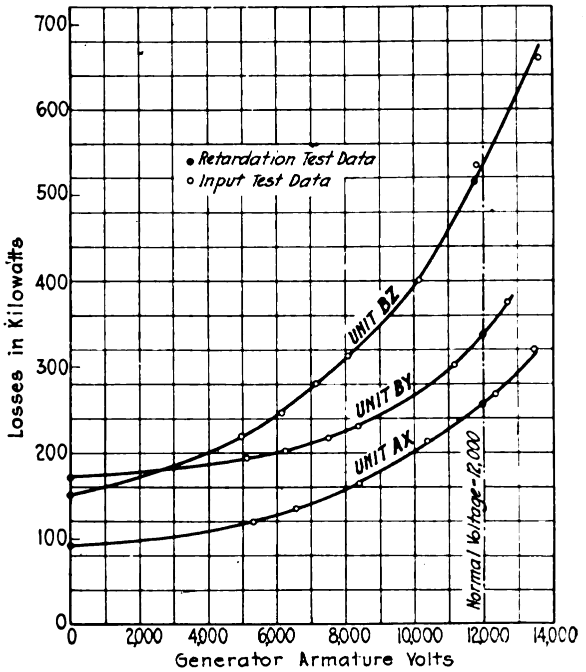

FIG. 6—FRICTION, WINDAGE AND IRON LOSSES OF THREE 32,500-KV-A. UNITS—NORMAL SPEED 150 REV. PER MIN.

The simplest and most practical method of bringing the generator up to speed is to drive it as a motor from

another generator of the same voltage. The driving generator can be of considerably smaller capacity than the one to be driven, no difficulty whatever having been experienced with a ratio of ratings of one to four. The driving and driven machines are synchronized from rest in a manner now well understood. Fig. 5 shows the connections as usually employed for all tests.

In the leads from the driving machine there should be an oil circuit breaker, and current transformers. For the latter, a primary ampere capacity of about 6 per cent of the rated current of the driven machine, with 5-ampere secondary, has been found satisfactory. Such a size is large enough to carry the current required to accelerate the driven machine (if not accelerated too rapidly), and is small enough to give good readings on standard 2.5- to 5-ampere ammeters and wattmeters when measuring the input to the driven machine. In any specific case the required size should be calculated from the estimated friction, windage and iron losses. Suitable means should also be provided for measuring voltage and power input. It is assumed that proper calibrations of all instruments and instrument transformers will be taken care of in the standard manner.

It is preferable that the machine under test be separately excited in order to eliminate complications. However, if a direct-connected exciter is used, allowance must, of course, be made for the output and losses thereof.

Procedure. It has been found most convenient to make tests in the following order:

1. Friction, windage and iron loss by input
2. Friction, windage and iron loss (or $W R^2$) by retardation
3. Friction and windage by retardation
4. Friction and windage and load loss by retardation

1. Friction, Windage and Iron Loss by Input.

Close fields of both machines and circuit breaker *A* (leaving *B* open,) Fig. 5, and synchronize from rest. Bring machines up to normal speed gradually so as not to dangerously overload current transformers. Raise voltage to 10 or 15 per cent above normal for first reading. Take readings of voltage, current, power input, field current and speed at successive voltages down as low as field controls will permit. Usually readings can be carried down to about half voltage. Take at least 10 readings at each point at 15 sec. intervals. Before each series of readings see that field current of driving machine is adjusted so that armature current is a minimum, with driven machine field adjusted for desired voltage.

2. Friction, Windage and Iron Loss by Retardation.

At completion of input test, as above, raise speed to about 15 to 20 per cent above normal, adjust field current for normal open circuit voltage at normal speed, as per saturation curve, and open circuit breaker *A*, Fig. 5. As speed decreases record revolutions and time by means of chronograph as described above. Read volts, field current and speed by tachometer, (for check only, if a reliable one is available) at time intervals synchronized with chronograph. Field current should remain constant throughout test. Records should continue until speed has decreased at least to half normal value.

This test can be repeated for as many values of field current or generator voltage as desired. However, a single test at rated voltage will usually be sufficient to check the input test and the value of $W R^2$. Should a good check not be obtained, however, it is desirable to repeat and correct the value of $W R^2$ if the value calculated from design appears to be persistently in error.

3. Friction and Windage by Retardation.

Synchronize from rest and bring to 15 or 20 per cent above normal speed. Open oil circuit breaker between machines and immediately open field switch of test machine. As speed decreases, record revolutions and time on chronograph and read speed on tachometer (if available) at times synchronizing with chronograph record. Record should be continued to well below half speed in order to obtain as much of this curve as possible for a purpose to be explained later. A single test should be sufficient to determine friction and windage.

4. Friction, Windage and Load Losses by Retardation.

With circuit-breaker *B* open, close circuit breaker *A* and synchronize from rest as usual. Raise speed to above normal as before. Quickly open circuit-breaker *A*, open field switch, close circuit-breaker *B*, close field switch and quickly adjust field current to give desired armature current as per closed circuit saturation curve. These operations can and should be completed before speed has come down to 10 per cent above normal, in order that steady conditions may exist while speed is passing through normal value. Record revolutions and time by chronograph, and make synchronized readings of speed and of field and armature currents. This test should be repeated at various armature currents in order to obtain data for a curve of stray-load loss versus armature current.

Separation and Determination of Friction and Windage. The nature of the friction and windage losses and the consequent laws governing the form of the friction and windage retardation curve furnish a means of separating the "apparent friction" from the "apparent windage" losses.

With a constant coefficient of friction, the friction loss should vary directly as the first power of the speed.

The windage loss, however, in accordance with the well-known laws governing the movement of air, should vary directly as the third power of the speed. It would seem, therefore, that the curve of windage and friction losses against speed, should have the form:

$$\text{Total friction and windage loss} = F\,S + W\,S^3 \qquad \textbf{(6)}$$

Where F may be called the coefficient of friction loss and W the coefficient of windage loss, S being the speed in rev. per min.

Upon plotting such a curve from the record of a fric-

tion and windage retardation test, it is found to conform exactly to this law.

TABLE II

Table II is the data from the graphic record of such a test, and Fig. 7 shows the values plotted from Table II.

The coefficients are readily found by substituting in equation (6) the values of total loss and speed for two points of the curve and solving simultaneously. For example, taking the values at 100 and 60 rev. per min. from a trial curve drawn for the test points of Fig. 7 and substituting in equation (6) we have the simultaneous equations:

$$372 = 100\,F + 1{,}000{,}000\,W$$

$$94 = 60\,F + 216{,}000\,W$$

Solving for F and W we have:

$$F = 0.355$$

$$W = 0.0003365$$

Recalculating for successive values of S, we have:

TABLE III
FRICTION AND WINDAGE LOSSES BY CALCULATION EQUATION (6)

(S) Rev. Per Min.	Friction Loss in Kw.	Windage Loss in Kw.	Total Loss in Kw.
40	14.2	21.6	35.8
50	17.7	42.0	59.7
60	21.3	72.7	94.0
70	24.9	115.5	140.4
80	28.4	172.0	200.4
90	31.9	245.0	276.9
100	35.5	336.5	372.0
110	39.1	347.0	486.1
120	42.6	581.0	623.6

Plotting these values we find the resulting curve, Fig. 7, to correspond with the test values with practical exactness at all speeds. This curve is quite sensitive to small changes in the values of the coefficients of friction and windage losses, and several trials are sometimes necessary before the correct coefficients are found to make the curve fit the test points at all parts of the

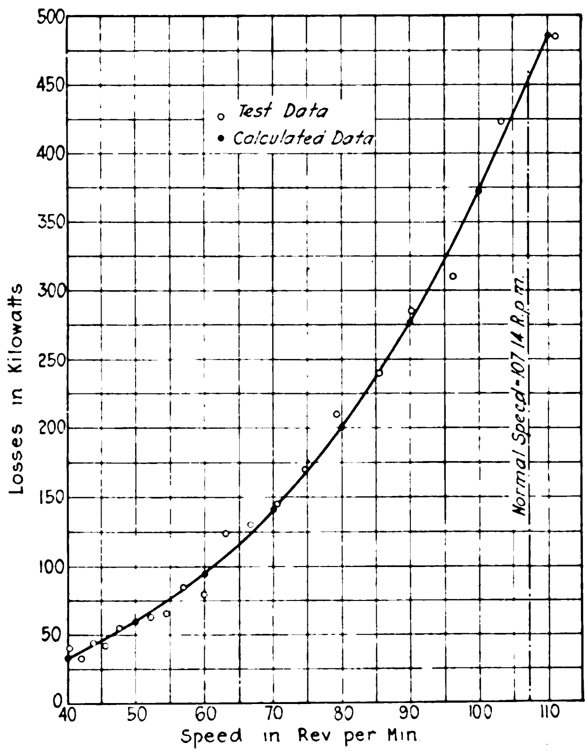

Fig. 7—Friction and Windage Losses of 65,000-Kv-a. Generator

curve. When this has been done, however, one can be quite confident that the resulting values of total losses are correct, whatever the separate values of "apparent friction" and "apparent windage" may represent, see Fig. 8.

It is indeed probable that even in the case of a test upon a generator alone, separated from its turbine, the "apparent friction" loss may include some of the windage and the "apparent windage" some of the bearing friction, since it seems probable that a small part of the

bearing losses are of such a nature as to vary with the third power of the speed. However, while there may be some doubt as to the exact composition of the two kinds of losses differentiated in this manner, their separation is nevertheless well worth while for the purpose (if for no other) of detecting the presence of any possible abnormal friction loss, such as a tight bearing or gland, or a rubbing turbine seal, which would surely show up in an abnormally large first power loss.

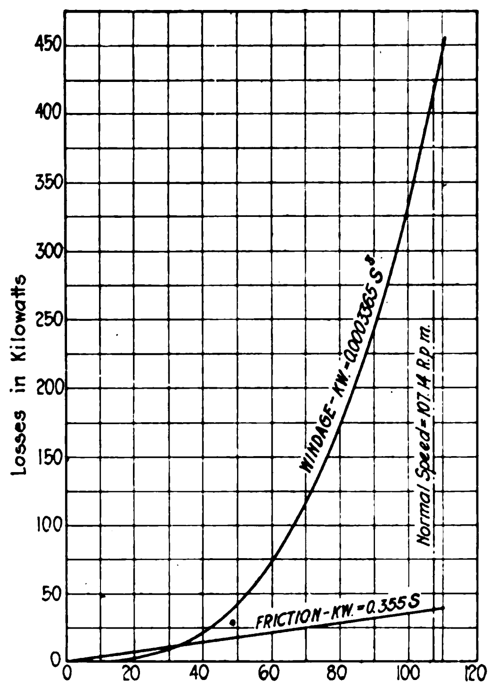

Fig. 8—Friction and Windage Losses of 65,000-Kv-a. Generator

However, the author believes, from experience in testing several different types and makes of generators by the above methods, that the separate "apparent friction" and "apparent windage" found by this method are very close to the actual friction and windage losses, when not complicated by other factors such as "disk friction" or "pumpage" losses in the turbine, due to the presence of water for cooling purposes.

Division of Friction and Windage Between Generator and Turbine. In those cases where tests are made with the turbine connected, the friction losses as above determined, will include turbine friction in bearings, glands and seals, and the "apparent windage" loss will include windage in the turbine and probably another loss due to the presence of a small amount of water in the turbine, which may be classed as "disk friction" or "pumpage." These losses can, at present, only be approximated, but by separating the first and third power losses by the method described above, these approximations can be handled with much more confidence than when the mechanical losses are all lumped together.

In an isolated case of a single unit, the division of the mechanical losses between generator and turbine is quite difficult, if not impossible. In a case, however, where several units of similar but different characteristics are being tested, it is often possible, by careful observations and comparisons, to make approximations which give results approaching the truth closely enough for practical purposes.

As an illustration of what may be done along this line, the steps taken in allocating the mechanical losses in three units of 32,500-kv-a. capacity, comprising three different combinations of turbines and generators will be described. If we designate the two turbine manufacturers by the letters *A* and *B*, and the three generator manufacturers by *X*, *Y* and *Z*, then we can designate the three units as *A X*, *B Y* and *B Z*.

The friction and windage losses of these three machines, all of the same capacity rating, and the steps by which they were allocated, are shown in the following tabulation:

TABLE IV
ANALYSIS OF FRICTION AND WINDAGE OF THREE 32,500-KV-A. UNITS

	Unit *A X*	Unit *B Y*	Unit *B Z*
Total Friction, Windage & Pumpage	91.65	171.5	151.05
Friction *H*	18.75	28.0	28.25

Turbine Pumpage (Est.)	12.9	40.0	40.0
Total Generator Friction & Windage	61.15	105.96	85.56

That portion of the loss which is proportional to the third power of the speed was at first thought to be entirely windage, but upon further investigation it was found that there might be a loss in the turbine of the nature generally called disk friction which also varies as the third power of the speed, and, owing to the different construction of the two types of tubine, it is reasonable to expect that under test conditions these losses might differ very markedly between the two types. This

presumption is further corroborated by the very great discrepancy between the measured so-called windage losses of $A\ X$ and $B\ Y$ and $B\ Z$, these losses in the case of $B\ Y$ being just about double the corresponding losses of $A\ X$, see Fig. 6. It hardly seems reasonable to charge this discrepancy entirely to true windage.

The same sort of reasoning applies also to the friction losses. The thrust and guide bearings of the three units do not differ materially, but there is a considerable difference in the nature and area of the turbine seals between the A and B designs, and it would, therefore, seem reasonable to expect that that portion of the friction loss which takes place in the seals would be somewhat in proportion to the areas of the contiguous surfaces.

Analysis of Friction Loss. At the time when Unit $A\ X$ was placed in service, the bearing manufacturer's engineers made a determination of the loss in the thrust bearing of this unit and stated that this loss was apparently about 20 h. p., or 15 kw. This value has been used as a basis for the analysis of the friction loss, it being assumed that the loss in these thrust bearings will vary in direct proportion to the weight that they carry. This loss has also been.further divided between the generator and turbine in proportion to their weights.

Upon subtracting the value thus determined for the thrust bearing on Unit $A\ X$ from the total friction losses as determined by test, there remains but slightly over seven kw. to be divided between the generator and turbine-guide bearings and turbine seals. In consideration of the smallness of this loss, the nature of the parts which create it, and the relation which might be expected to exist between the generator guide and thrust-bearing losses, it was concluded that two kw. would be a reasonable portion of this loss to assign to the generator-guide bearings, the remainder being charged to the turbine.

In the case of the other two units, the total measured friction losses were considerably greater and the thrust-bearing friction was also somewhat greater, due to the increased weights of these machines over that of Unit $A\ X$. There appeared, however, no reason why the guide-bearing loss should be any greater than on Unit $A\ X$, and the assumption checks with the observed fact that the guide-bearing oil temperatures of the three units do not materially differ from each other.

There is then left chargeable to turbine friction approximately 13 kw. in Units $B\ Y$ and $B\ Z$, or about two and one-half times the corresponding loss in Unit $A\ X$, which ratio would appear reasonable from a consideration of the two turbine designs. This results in the friction losses of the three generators differing by only such amounts as are accounted for by their different weights.

Analysis of "Windage" Loss. In the case of the so-called windage losses—all those losses varying as the third power of the speed—the total of such losses in the case of Unit $A\ X$ was but 72.9 kw. As stated above there is too great a discrepancy between this value and those of similar losses determined for the other two units to be all charged to generator windage, and it is accordingly necessary to find some other difference between the two turbine designs to account for a part of this discrepancy. The value of this loss is about 20 kw. greater for Unit $B\ Y$ than for Unit $B\ Z$. This difference is believed to be reasonably accounted for by the fact that in Unit $B\ Y$ a large volume of air was allowed to discharge around the end windings of the armature, no attempt having been made to limit the discharge at these points to merely that necessary to maintain the temperature within safe limits, whereas, in the case of Unit $B\ Z$ the corresponding openings have been partially blocked for this purpose. The additional air moved in the case of Unit $B\ Y$ might account for the 20-kw. difference.

There then remains a difference of approximately 50 kw. between these losses on Units $A\ X$ and $B\ Z$. Part of this difference is undoubtedly in the generator and a part in the turbine. The designer of the Generator X was particularly careful to decrease to the greatest possible extent the windage loss by careful fan design and by the addition of sheet-metal shrouds on the generator-rotor spider and fan for the purpose of directing the air currents, while apparently such provisions are not carried out to the same extent in the case of Generator Z.

As to the turbines, an inspection of the respective runner designs indicates that in the case of Turbine B the lubricating water from the lignum-vitae bearing is much more apt to get away through the upper seals of the turbine than is the case of Turbine A, and this might readily account for a considerable part of the observed difference in losses.

A formula was given in the water-wheel test code for determining the turbine windage, but in this case this formula gave a value of approximately 50 kw., which, in the case of Unit $A\ X$ is obviously far too high, as it would leave but about 23 kw. for generator windage. There is, however, undoubtedly some windage loss in the turbines under test conditions, and this was approximated by reference to fan data. It was found that the shut-off power of a fan was in the neighborhood of 20 per cent of the full-load power, and it was assumed that the 50 kw. resulting from the above mentioned formula would represent the full-load power of the turbine runner as a fan, which appeared reasonable from a consideration of its dimensions and in comparison with fan data. It was then assumed that the shut-off power or windage with turbine gates closed would be 20 per cent of this, or 10 kw. This was assumed to be the same for all three turbines. There was then left, in the case of Unit $A\ X$, 62.9 kw. to be divided between generator windage and turbine disk friction. Of this 50 kw. was arbitrarily charged to generator windage, as this seemed a reasonable value, and left an amount of 12.9 kw. chargeable to turbine disk friction. In the

case of Units B Y and B Z, it was thought that the disk friction might be approximately three times that of Unit A X, and was accordingly put at 40 kw., leaving for generator windage 93.5 kw. in the case of Unit B Y, and 72.8 kw. for Unit B Z, as compared with the 50 kw. assumed on Unit A X. The value of 50 kw. (40 + 10) for turbine windage and disk friction happens to be the same as would have been assigned to turbine windage had the test code formula been used, hence, should not be open to serious criticism.

The final values of generator friction and windage then become for Unit A X, 61.15 kw.; Unit B Y, 105.96 kw.; and Unit B Z, 85.56 kw. We have two checks on these figures; first, the designer of Generator Z stated that he estimated the friction and windage of his generator at 80 kw., and second, the designer of Generator Y, that of his at about 109 kw. We have a further check on the accuracy of the resulting values of generator efficiency in that the efficiencies of the turbines of Units B Y and B Z, based on the values of generator efficiency thus arrived at, checked each other exactly.

Separation and Determination of Electrical Losses

Iron Loss. Obviously the iron loss is determined by subtracting the friction and windage from the iron-loss

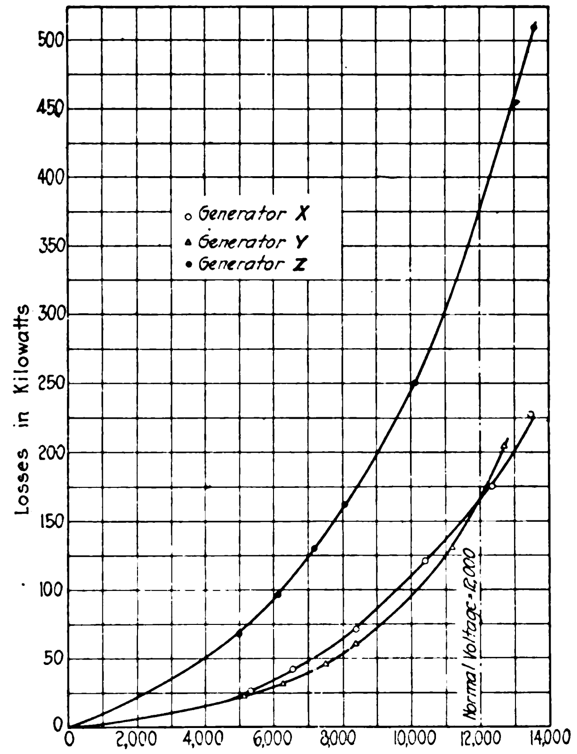

Fig. 9—Iron Losses of Three 32,500-Kv-a. Generators

friction and windage as determined either by the input or by the retardation test. Fig. 4 shows iron loss, friction and windage data for the 65,000-kv-a. unit, and Fig. 6 for the three 32,500-kv-a. units. The values of the friction and windage losses, of course, determine the termini of these curves on the zero voltage axis, thereby giving the necessary data for the completion of the lower part of the curves. Fig. 9 shows iron losses alone for the three 32,500-kv-a. generators and Fig. 10 for the 65,000-kv-a. generator.

Stray-Load Losses. Similarly the stray-load loss is

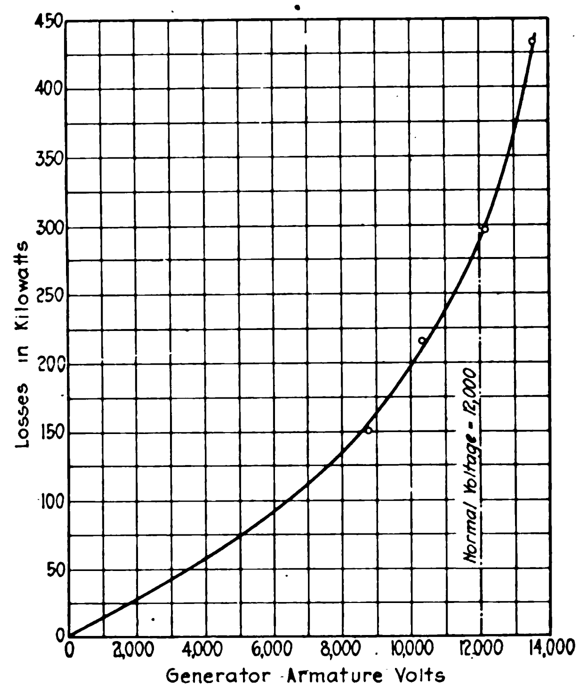

Fig. 10—Iron Losses of 65,000-Kv-a. Generator

determined by subtracting the friction and windage and armature $I^2 R$ loss from the appropriate test values. This has been done for the 65,000-kv-a. generator, the various steps by which the stray-load loss has been determined are indicated in Fig. 11.

Following the same general principles used in determining the friction and windage, and the iron loss, the test points are first determined and plotted for the delineation of a curve of loss against speed as obtained by the retardation test. In Fig. 11 these test points for armature currents of 1554 amperes, 2145 amperes, and 3156 amperes are shown respectively at a, b and c.

These points do not look very encouraging as almost any kind of a curve can, seemingly, be drawn through them. However, in delineating these curves, we are entitled to use all the information which we have, so, before drawing in the curves, it may be indicated on the sheet just what is known about the losses which are to be deducted. We, therefore, draw in the friction and windage loss curve, as per Fig. 7.

As to the $I^2 R$ loss, it is known both from theory and observation, that the short-circuit current remains practically constant at all speeds, hence, the $I^2 R$ loss is constant throughout the test. It is possible, therefore, to add a constant $I^2 R$ loss to the friction and windage-loss curve, obtaining the corresponding curves shown in Fig. 11.

The difference between this curve and the total-loss curve is the "stray-load" loss, and there should be some consistent relationship between the stray-load loss and speed. Three assumptions are possible:

1. Stray-load loss decreases as speed increases.
2. Stray-load loss constant as speed increases.
3. Stray-load loss increases as speed increases.

If the stray-load loss is caused mostly by eddy currents in the copper, as seems most likely, it would appear that it should increase with frequency, and the test points indicate in general that it does so. If so, three assumptions are again possible as to a possible

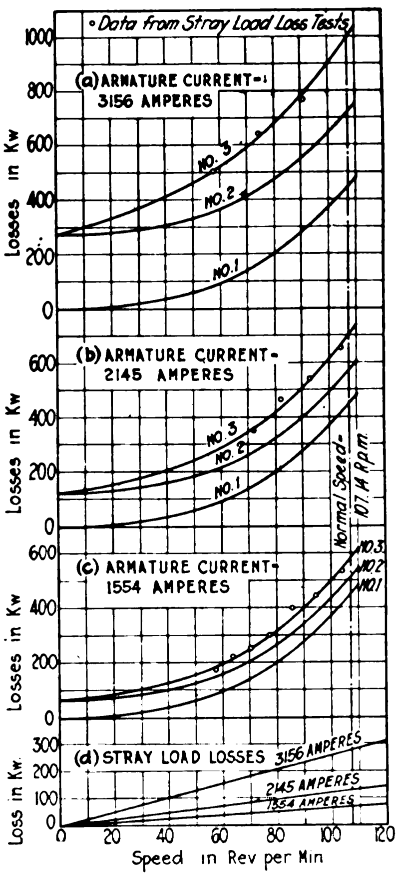

FIG. 11—RETARDATION TEST FOR STRAY LOAD LOSSES OF 65,000-KV-A. GENERATOR

Curve No. 1—Friction and windage losses
No. 2—Curve No. 1 plus $I^2\ R$ losses
No. 3—Curve No. 2 plus stray load losses

exponent of the power of the speed by which it varies, that is, if it is assumed that:

$$\text{Stray-load loss} = C\ S^n \qquad (7)$$

where C is a constant,
n may be

1. less than unity
2. equal to unity
3. greater than unity

In order to determine which of these assumptions most nearly agrees with the test data, trial curves were drawn and the speed-time curve reconstructed from points taken from the trial curves. The reconstructed curve based upon the assumption of $n = 1$ shows the better agreement, and this assumption was consequently used in drawing the final curve through the test points. The differences, however, between the results of the three assumptions are very slight, and none of them are probably scientifically true.

In drawing the curves, a point was selected on each of the trial curves through which it appeared the curve would have to pass whatever its form. From these values, the corresponding friction, windage and iron losses were deducted, the residual values being plotted on a rectangular scale and straight lines drawn through these points and the origin. These three lines, shown at *d* Fig. 11 are then the most probable curves of stray-load losses for different speeds at the three values of armature current. These three curves were then added to the friction, windage and $I^2\ R$ loss curves to produce the total-loss curves as shown. It was found that the stray-load loss at any given speed varied almost exactly as the square of the current, the chance agreement of the trial points in this respect being so close that the final curves were intentionally so drawn.

These results would *seem* to indicate the following conclusions:

1. The short-circuit stray-load losses are due (at least mostly) to an increase in the effective resistance of the armature conductors, due, no doubt, to a displacement of the current in the conductors—usually called "eddy currents."
2. This increase in effective resistance varies with the speed or frequency, and appears to be substantially proportional to the first power thereof.
3. The increase in effective resistance is apparently independent of the armature current.

From these results, it would appear that, practically, the effective resistance of the armature would be expressed by the formula:

$$R_f = R\,(1 + K\,f) \qquad (8)$$

where
R_f is resistance at frequency f
R is resistance for direct current
and
K is a constant.

While these conclusions *seem to be* indicated, it is, fo course, not safe to generalize from a single test, and further and more accurate determinations will be required to establish these relations definitely, if indeed, they actually exist at all.

However, in this case, it is apparently true that, for all practical purposes, the determination of the short-circuit stray-load loss for any current and any speed may be made from a single accurate test at one current and one speed. If formula (8), or one similar to it, should prove to be generally true, it would appear that some independent method of predetermining the coefficient (K) would be extremely useful.

Conclusions

1. The retardation method for determining certain of the losses in large generators is a useful, accurate, consistent and easily applied method, and deserves more extensive use and fuller official recognition.

2. The retardation method of measuring friction and windage losses contains within itself the means of separating these losses from each other. This is a very useful property when it is necessary to allocate such losses between the generator and its turbine. It is also useful for detecting abnormal friction or windage.

3. The determination of a loss at different speeds, which is a natural application of the retardation method, furnishes a means not only of more accurately determining such loss at normal speed, but also furnishes a means of throwing new light upon the nature of certain of the losses.

4. Development of apparatus and refinement of methods of carrying out retardation tests are desirable. An instrument to measure the rate of retardation directly, should be a possibility not difficult to realize.

Three Methods of Measuring Dielectric Power Loss and Power Factor

BY E. D. DOYLE[1] and E. H. SALTER[1]
Member, A. I. E. E. Associate, A. I. E. E.

Synopsis.—*The paper presents a brief description of the methods of measuring dielectric power loss and power factor in commercial use at the Electrical Testing Laboratories.*

The several methods are handled individually and their advantages and disadvantages listed.

Appendixes are included on the use of the shunted electrodynamometer as an ammeter, determination of compensation, effect of incorrect compensation in the wattmeter shunt, effect of slightly unbalanced voltages on three-phase measurements, a three-phase wattmeter switch and shielding, grounding, etc.

Introduction

The very fact that a symposium on methods of measuring dielectric power loss and power factor has been arranged is an indication that such measurements offer considerable difficulties, particularly when applied to present-day dielectrics. The purpose of this paper is to describe and discuss the methods now employed at the Electrical Testing Laboratories for such measurements.

Originality is not claimed for the methods described, but they have been improved and adapted as need for them has arisen. Experience has shown each to be satisfactory for the class of work for which it has been developed.

General

The three general methods to be described and the measurements for which they are adapted are as follows:

1. Compensated Wattmeter Method
   a. For single-phase measurements on cables
   b. For three-phase measurements on cables
2. Phase-Defect Compensation Method
   a. For high-voltage single-phase measurements on cables
   b. For single-phase measurements on low-voltage condensers of high capacitance
3. Transformer Bridge
   a. For single-phase measurements on very low capacitances (short pieces of cable, oils, compounds, sheet materials, etc.)

1a. The Compensated Wattmeter for Single-Phase Measurements.

This method consists in a direct measurement of the dielectric power loss in watts when an alternating potential is applied to the cable under test. As there is always a certain amount of "leakage" power in the test circuits and instruments, a measurement is first made of this "leakage" before the cable is connected for test. This "leakage" loss is then subtracted from the total loss with the cable or other dielectric in circuit in order to obtain the "net" or actual loss in the material under test.

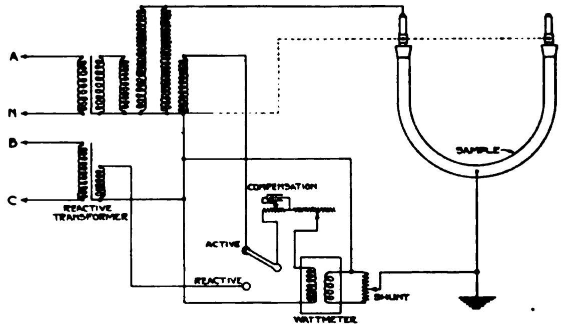

Fig. 1

This direct measurement is made using a shunted reflecting electrodynamometer wattmeter in connection with a potential transformer. The phase angle of the potential transformer and the self inductance of the

1. Both of Electrical Testing Laboratories, New York City.

Presented at the Regional Meeting of District No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

potential coil of the wattmeter are compensated for by the use of a shunted condenser of the proper value in the potential circuit of the wattmeter. The self inductance of the current element of the wattmeter is compensated for by the use of a shunted condenser in the wattmeter shunt.. A diagram of the complete circuit used is shown in Fig. 1.

The equipment used in making such measurements is as follows:

1 Insulating transformer
1 Testing transformer
1 Voltage transformer
1 Reflecting electrodynamometer wattmeter
1 Compensated wattmeter shunt
1 Voltage-circuit resistance with compensation
1 Calibrating load
1 Lamp and scale
1 High-resistance voltmeter
1 Frequency meter
1 "Reactive" insulating transformer

When using this method the wattmeter is calibrated on low voltage against a resistance load. In this

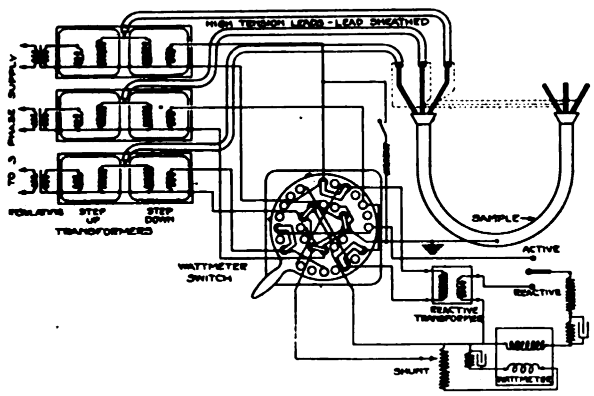

Fig. 2

operation the voltage circuit resistance is adjusted to give some even scale constant such as 0.001 watt loss in the high-voltage circuit per millimeter scale deflection.

After the calibration is completed the resistance in the compensation circuit is set for its correct value for the first test voltage. Since the burden on the potential transformer is practically constant from day to day, regardless of the sample under test, the value of compensating resistance necessary for various test voltages can be determined in advance by the methods described in Appendix II.

For speed in testing it is the usual practise to take a complete set of "leakage" readings covering the full range of test points and follow this immediately by "cable on" readings made at the same test voltages. These readings are referred to as "active" readings as distinguished from the "reactive" readings referred to below.

In order to determine power-factor it is then necessary to measure either the current, Appendix I, or the apparent power, reactive volt-amperes. It is the practise at these Laboratories to determine the reactive volt-amperes in this case rather than the current. With a three-phase, Y-connected supply and the test set operated on one phase, a transformer with a ratio of $\sqrt{3}$ to one connected across the remaining two phases furnishes a potential supply which makes it possible to read the reactive volt-amperes directly. In this case, as well as in the power readings, "leakage" readings and "cable on" readings are made for all test points. These readings are referred to as "reactive" readings.

A typical set of data is as follows:

	Active		Reactive
Voltmeter indication		20	
True voltage—kv		10	
Compensating resistance		249	
"Leakage" Measurements			
Dynamometer indication	−33		−67
Shunt	1		1
Total deflection	−33		−67
"Cable On" Measurements			
Dynamometer indication	112		168
Shunt	1		50
Total deflection	112		8400
Leakage deflection	−33		−67
Net deflection	145		8467
Net volt-amperes	0.145		8.467
Cotangent		0.0171	
Power factor, per cent		1.71	

The time required for an operator to take complete data on a test requiring six test voltages is about one-half hour. During this time he can make all computations as indicated in the sample data, these computations being made while waiting for the wattmeter to assume a steady deflection.

The sensitivity of this equipment is, of course, fixed in the calibration and remains constant throughout the test range.

The accuracy depends chiefly on the accuracy of compensation. With the present methods of determining compensation it is believed that an accuracy of $\pm$ 0.05 per cent in power factor should be obtained.

This type of equipment is sensitive to external conditions. The loss read by the wattmeter varies as the square of the applied voltage, so that small voltage variations multiply in their effect on the loss reading. The reactive volt-amperes vary directly as the frequency and as the voltage, hence these conditions must be constant and correct.

Dielectric power loss and power-factor measurements should be made using sine-wave potential. With this method, however, the power-loss is measured for the wave used, whatever its form may be.

Advantages:

1. Rapid operation—five minutes per test point including time for computations
2. Simple operation
3. Not affected by wave form of supply
4. High sensitivity

Disadvantages:

1. Accuracy of method depends on accuracy of compensation
2. Particularly susceptible to variations in supply voltage

1b. The Compensated Wattmeter for Three-Phase Measurements.

This method consists in a direct measurement of the dielectric loss in watts when a three-phase alternating voltage is applied to the sample of cable under investigation.

The method is essentially the three-wattmeter method for the determination of power in a three-phase, four-wire circuit. This method has been simplified by the use of one wattmeter in connection with a specially designed switch for connecting the wattmeter in each of the three circuits as desired. A complete diagram of this circuit is shown in Fig. 2.

The operation of this equipment is essentially the same as that described in Method 1a. Since it is very difficult to obtain balanced three-phase voltages, it has been found that best results are secured by holding the voltage constant on one phase, rather than trying to adjust to the correct voltage on each phase. The reasoning back of this is to maintain the conditions constant for each test point. When working on an unbalanced system this would not be true if the voltage were adjusted on each phase when the wattmeter is read.

The equipment used in making these tests is the same as that described in Method 1 *a*, except that three insulating, three testing and three potential transformers are required together with the special wattmeter switch, Appendix V.

A typical set of data from one of these tests is as follows:

Voltmeter indication		29	
True line-kv		10	
Compensating resistance		279	
	Active		Reactive
"Leakage" Measurements			
Dynamometer Indication Ph. I	−24		96
" " " II	0		141
" " " III	−52		120
" " Sum	−76		357
Shunt	1		1
Total deflection	−76		357
"Cable On" Measurements			
Dynamometer Indication Ph. I	−36		87
" " " II	107		81
" " " III	−42		79
" " Sum	29		247
Shunt	10		200
Total deflection	290		49400
Leakage deflection	−76		+357
Net deflection	366		49043
Net volt-amperes	0.366		49.043
Cotangent		0.0075	
Power factor, per cent		0.75	

The advantages and disadvantages of this method are essentially the same as those described in Method 1a.

2a. Phase-defect Compensation Method for High-Voltage Measurements.

This method consists in a determination of the power factor or phase angle of the sample under test by a direct comparison of its apparent phase defect angle with that of a "no-loss" air condenser.

In this method a reflecting type electrodynamometer wattmeter, connected as for measuring watts loss, is made to read zero by changing the phase of the current in the potential circuit by inserting inductance of known value. Such a balance is obtained, first, against a "no-loss" air condenser, and then against the sample.

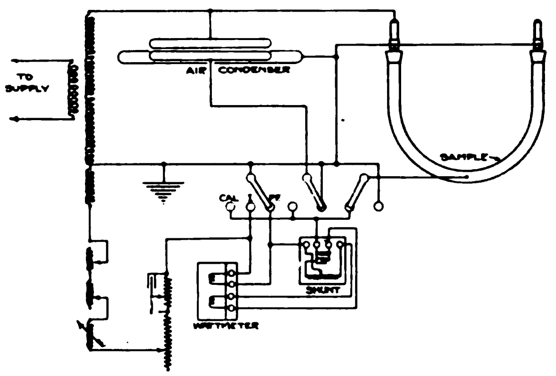

FIG. 3

From the difference in shift necessary the power factor or phase angle of the sample is obtained.

Complete connections used in this test are shown in Fig. 3.

The equipment used is as follows:

1 Testing transformer
1 Reflecting electrodynamometer wattmeter
1 Dynamometer shunt
1 Voltage circuit resistor with compensation
1 50- to 250-milhenry constant resistance tapped inductor
1 6- to 50-milhenry variable inductor
1 Lamp and scale
1 High-resistance voltmeter
1 Frequency meter
1 High-voltage variable air condenser, "no-loss"

In using this method the sample and the "no-loss" air condenser are kept connected to the transformer at all times in order to maintain the relative phase positions. For convenience in computing, the potential circuit resistance is kept constant at a value in ohms equal to 6 π times the frequency in cycles per second.

In order to determine the dielectric power loss the charging current is measured, using the electrodynamometer as an ammeter, Appendix I. Then from the charging current, the power factor and the test voltage, the dielectric power loss is computed.

A typical set of test data and computations is as follows:

Voltmeter indication	20
Test kv	
Cable (Condenser Connected Directly to Ground)	10
Potential circuit resistance	1131
Observed Inductance—Direct	44.0
" " —Reverse	43.8
" " —Average	43.9
Ammeter shunt	5
Ammeter reading	452
True milliamperes	2.74
Condenser (Cable connected directly to ground)	
Observed inductance—Direct	35.0
" " —Reverse	35.6
" " —Average	35.3
Difference in inductance	8.6
Power factor of sample, per cent	0.29
Dielectric power loss, watts	0.079

To determine the constant of the ammeter the electrodynamometer is calibrated against a resistance load. This connection is obtained with the selector switch on "calibrate."

Fig. 4 is the vector diagram for this method where

E = Test voltage
I_a = Current to air condenser
I_s = Current to sample
E_p = Voltage applied to potential circuit
I_1 = Current in potential circuit when balanced against air condenser
I_2 = Current in potential circuit when balanced against sample
ϕ_1 = Apparent phase defect angle of air condenser
ϕ_2 = Apparent phase defect angle of sample

The computation of the power factor is based on the following theory. If L_1 is the inductance setting for

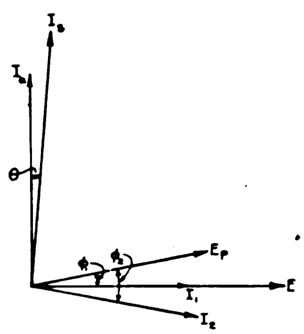

FIG. 4

zero reading on the air condenser, the phase shift of the current in the potential circuit in order to obtain the balance is

$$\tan \phi_1 = \frac{\omega L_1}{R} \tag{1}$$

Likewise, if L_2 is the inductance setting for balance against the sample, the phase shift of the current in the potential circuit is

$$\tan \phi_2 = \frac{\omega L_2}{R} \tag{2}$$

Since these are all small angles, the tangent is numerically approximately equal to the sine of the angle. Then, if θ is the phase-defect angle of the sample (difference between the actual angle and 90 deg.)

$$\sin \theta = \tan \phi_2 - \tan \phi_1 = \frac{\omega}{R}(L_2 - L_1) \tag{3}$$

or

$$\text{Power factor} = 100 \sin \theta = \frac{100\ \omega}{R}(L_2 - L_1) \tag{4}$$

But R has been made equal to 3 ω

Therefore,

$$\text{Power factor} = \frac{L_2 - L_1}{30} \tag{5}$$

when L_2 and L_1 are read in millihenries.

The computation of the power-factor is so simple that it is readily made while waiting for the ammeter to assume a steady deflection.

Computation of the charging current depends upon the ammeter connection used. See Appendix I for methods of using the electrodynamometer as an ammeter.

The time to take a set of readings covering six-test voltages is approximately one-half hour, during which time the power-factor values are also computed. The remainder of the computations may take as much as an additional 20 min.

The sensitivity of this equipment, when used for power-factor measurements, varies with the test voltage and the charging current to the sample under test. It is naturally more sensitive under higher currents and voltages.

When making the power-factor balance, voltage variations cause changing sensitivity, although at balance voltage variations have no effect (assuming no change in power factor with voltage). Likewise, frequency variations affect the sensitivity on power-factor measurements as well as change the apparent defect angle. On current measurements any variable causing a varying charging current (voltage or frequency) causes a variable reading, which is particularly objectionable since the deflection varies approximately as the square of the current.

The accuracy of this method is dependent chiefly upon the operator and upon the "no-loss" condenser. A careful operator should be able to make measurements to within ± 0.05 per cent power factor. The losses as computed from the current and power-factor should be well within ± 5 per cent accuracy.

In this equipment errors in wave form introduce an error in the power factor since it is computed on the basis of a sine wave. For harmonics which do not run above five per cent in value this is negligible.

Advantages:
1. Rapid operation
2. Simple operation

Disadvantages:
1. Variable sensitivity
2. Accuracy dependent on operator and on "no-loss" condenser
3. Frequency and voltage must be maintained constant

2b. Phase-Defect Compensation Method for Measurements on Low-Voltage Condensers of High Capacitance.

The measurement of losses in low-voltage condensers of high capacitance (such as are used for power-factor correction) may be accomplished by a modification of

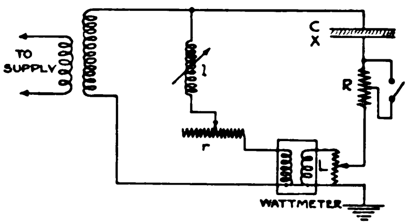

Fig. 5

Method 2a. The method then consists in a determination of the power factor of the test condenser by a comparison of the apparent phase-defect angles with different known values of resistance in series with it.

The diagram of connections is shown in Fig. 5. Here again a reflecting type electrodynamometer wattmeter is used, connected as for power measurement, and made to read zero by changing the phase of the current in the potential circuit by inserting inductance of known value. Such a balance is obtained for each of two or more known values of resistance in series with the test condenser.

In employing this method the following equipment is used:

1 Resistor having two or three steps
1 Reflecting electrodynamometer wattmeter
1 Lamp and scale
1 Variable inductometer
1 Voltage circuit resistor
1 Voltmeter
1 Frequency meter

Then, if

X = Series resistance of test condenser
C = Capacitance of test condenser
R = Resistance in condenser circuit (not including X)
L = Inductance of current circuit (usually that of current coil of wattmeter)
l = Total inductance of voltage circuit
r = Total resistance in voltage circuit
$\omega = 2\pi f$,

Fig. 6 shows that at balance

$$\frac{\omega l}{r} = \frac{X + R}{\dfrac{l}{\omega C} - \omega L} \tag{6}$$

When l_1, r_1 and l_2, r_2 are the inductance and resistance values at balance corresponding to R_1 and R_2, respectively, the following equations can be deduced.

$$X = \frac{r_2 R_2 l_1 - r_1 R_1 l_2}{r_1 l_2 - r_2 l_1} \tag{7}$$

$$C = \frac{l_1}{r_1 (R_1 + X) + \omega^2 L l_1} \text{ or } \frac{l_2}{r_2 (R_2 + X) + \omega^2 L l_2} \tag{8}$$

If r_1 can be kept equal to r_2, equation (7) reduces to

$$X = \frac{R_2 l_1 - R_1 l_2}{l_2 - l_1} \tag{9}$$

On the other hand, if a variable inductor is not available and r must be varied, equation (7) reduces to

$$X = \frac{r_2 R_2 - r_1 R_1}{r_1 - r_2} \tag{10}$$

This latter arrangement produces one peculiar condition in that the sensitivity of the meter may change more rapidly than the phase angle of the potential circuit thus causing the electrodynamometer indication to

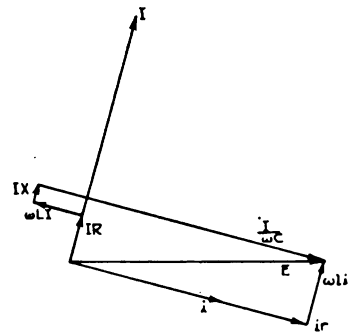

Fig. 6

become greater for a time as the balance point is approached.

A typical set of observed data and calculated results are shown below:

Test voltage, volts		440	
Frequency, cycles per sec		60	
Current-coil inductance, henrys		0.008	
Voltage-coil resistance, ohms		8000	
Resistance of current coil and leads, ohms		18	
"Test" resistance in current circuit, ohms	0		10
Total resistance in current circuit, ohms	18		28
Inductance of voltage circuit, millihenrys	400		588
Series resistance of test condenser, ohms		3.3	
Capacitance of test condenser, μ f		22.6	
Power-factor test condenser, per cent		2.81	
Loss in test condenser, watts		46.3	

Advantages:
1. No standard condenser needed
2. Settings only indirectly affected by frequency

Disadvantages:
1. Sensitivity variable
2. Constants of circuits must be known accurately

3a. The Transformer Bridge.

By this method the capacitance and equivalent shunting resistance are determined by comparison of the test sample with a "no-loss" air condenser. Each is inserted separately in one circuit of the bridge while the other circuit of the bridge containing known capacitances and resistances is adjusted until the currents in the two circuits are equal in magnitude and opposite in phase. From these values of capacitance and resistance the power factor and dielectric loss are computed.

A diagram of the circuit is shown in Fig. 7. The detector used consists of a synchronous commutator and a d-c. galvanometer. The rectifier is provided with two sets of brushes spaced 90 electrical degrees apart so that when properly set the bridge may be balanced for either component (active or reactive)—each practically independently of the other.

The balance circuit is unique in the use of a four-dial 100,000-ohm resistance box in connection with a

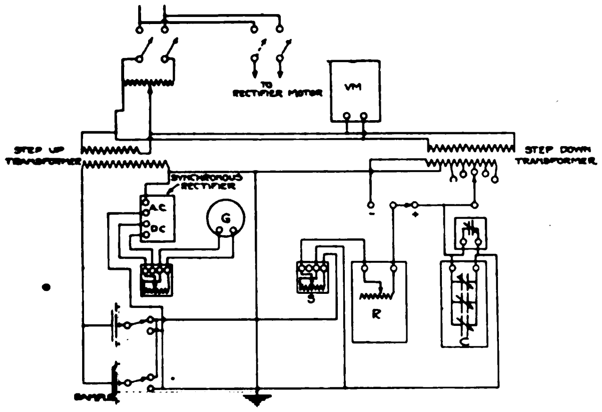

FIG. 7

universal shunt in order to simulate a continuously variable resistance of 0- to 500-megohm range. This is obtained by connecting the shunt across the detector and using the movable point as a connection for the resistance circuit.

Under certain conditions the resistance component required of the balance circuit is negative. Such a condition is provided for by an additional winding on the balance transformer as shown in Fig. 7.

The equipment used in this bridge consists of

1 D-c. reflecting galvanometer
1 Lamp and scale
1 Synchronous commutator
1 10,000-ohm galvanometer shunt
1 2000-ohm galvanometer shunt
1 4-dial, 100,000-ohm resistor
1 3-dial, 1 micro-microfarad mica condenser
1 1000-micro-microfarad variable air condenser
1 High-resistance voltmeter
1 Voltage regulator
1 Small step-down transformer
1 Testing transformer
1 High-voltage variable air condenser

In this method also, both the sample and the air condenser are kept connected to the testing transformer, each being connected directly to ground when not connected into the test circuit. This maintains circuit conditions constant at all times.

A set of typical test data is as follows:

	Air Condenser	Sample
Capacitance reading	0.2048	0.4378
Resistance reading	84000	42100
Shunt used	20	5
Tan ϕ	0.0077	0.0288
Power factor of sample, per cent		2.11

The tangent of the *apparent* defect angle, ϕ, is computed as for a parallel circuit

$$\tan \phi = \frac{1}{\omega C R S} \tag{11}$$

where

$\omega = 2 \pi f$
C = Capacitance read
R = Resistance read
S = Multiplying power of shunt

The defect angle of the sample is then the difference of these two angles, and since the angles are small,

Power factor $= \tan \phi_2 - \tan \phi_1$

where

ϕ_1 = the apparent defect angle of the air condenser

and

ϕ_2 = the apparent defect angle of the sample

The capacitance of the test sample is obtained from the capacitance read by

$$C_s = C \times r \tag{12}$$

where

C_s = Capacitance of sample
C = Capacitance read
r = Transformer ratio between test and balance circuits.

The time required for readings is about three minutes per test point. This includes the time for balances against both the air condenser and the sample.

Computations are not readily made during the test so that the time required for complete results on a test of six test points would be about one-half hour.

The sensitivity of this equipment is a function of the current in the test circuit and the galvanometer used. Since a d-c. galvanometer of medium high sensitivity (500 meg.) is used, the resultant sensitivity is high.

Accuracy is such that capacitances of the order of 50 micro-microfarads can be measured to within better than one per cent, while the power factor can be determined within $\pm$ 0.05 per cent (absolute value).

The bridge is extremely sensitive to leakages, so that all high-potential parts must be completely

shielded and all low-potential wiring metallically sheathed.

Frequency and voltage change affect the results only in so far as they change the properties of the test sample.

Potential waves of other than sine characteristics affect both the test and balance circuits alike and cause error only if neglected in the computations—the bridge

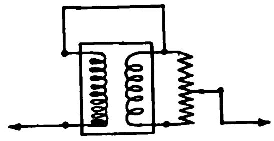

FIG. 8

determines the capacitance and resistance components for the wave applied.

Advantages:
1. Rapid operation
2. Simple operation
3. Very high sensitivity
4. Measurement range
   Capacitance 1-1000 micro-microfarads
   Power factor 0-100 per cent
5. Independent of frequency and voltage variations
6. Accuracy high

Disadvantages:
1. Very sensitive to leakages

Appendix I

THE USE OF THE REFLECTING ELECTRODYNAMOMETER AS A UNIVERSAL SHUNTED AMMETER

There are two methods of using the reflecting type electrodynamometer as a universal shunted ammeter. The first is that shown in Fig. 8. In this case only one coil is shunted and, providing the dynamometer has a uniform watt scale, the instrument follows the law,

$$\Delta S = K^2 I^2 \text{ or } I = \frac{\sqrt{\Delta S}}{K} \quad (13)$$

where

Δ = the deflection in millimeters
S = the multiplying factor of the shunt
K = the ammeter constant
I = the current

It is preferable under some circumstances to shunt

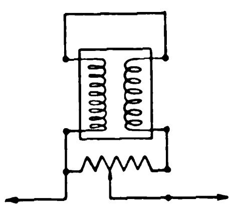

FIG. 9

both coils as shown in Fig. 9. The instrument then follows the law,

$$\Delta S^2 = K^2 I^2 \text{ or } I = \frac{S\sqrt{\Delta}}{K} \quad (14)$$

In this latter case, if the instrument can be calibrated to be direct reading on one shunt the product of the reading on this scale and the shunting value gives the current on any shunt. In the first case it is necessary to compute the constant over the range used and then the current which is a longer process.

Appendix II

DETERMINATION OF COMPENSATION

a. *Using a "no-loss" Air Condenser.*

To determine the correct wattmeter compensation for a given voltage, set air-condenser plates as close together as safe operation permits and read the wattmeter deflection for a series of values of "compensation resistance." These results when plotted, with wattmeter reading as abscissas and the square of the "compensation resistance" as ordinates, will give a straight line. Similar sets of data are then taken for a wider setting of the air condenser. These straight lines should then all cross at a point, corresponding to the correct value of compensation, at which point the wattmeter reading should be a constant regardless of the condenser spacing.

While this method is described as for a "no-loss" air condenser, it applies equally well for a "constant-loss" variable condenser. Leakages play no part, providing they are constant for each voltage.

This procedure, while applying to single-phase equipments in particular, is readily adapted to three-phase equipments. In this case, each phase is handled separately as for single-phase determinations and then the average of the three values used as the correct three-phase compensation.

b. *Using a Built-up Three-Phase Load.*

A second scheme, sometimes more convenient for determining three-phase compensation, is to take three single-phase loads of approximately the same capacitance and loss, say three pieces of single-conductor cable, on which determinations can first be made by single-phase test methods. These loads can then be combined into a three-phase load and the "compensation resistance" adjusted until the loss measured under three-phase potential equals the sum of the losses measured at a corresponding single-phase potential.

Appendix III

EFFECT OF INCORRECT COMPENSATION IN WATTMETER SHUNT

Incorrect compensation in the wattmeter shunt will introduce no error if the phase defect compensation method is used. Any such phase error will affect both balances of the wattmeter alike and hence be eliminated when the difference is taken.

In the straight wattmeter methods, however, incorrect compensation in the wattmeter shunt will cause an error unless the potential circuit compensation values are obtained as in Appendix II. Mathematical analysis and actual tests have shown that any error

caused by incorrect compensation in the wattmeter shunt appears as a constant angular error independent of shunt position.

Appendix IV

Effect of Slightly Unbalanced Voltages on Three-Phase Measurements

When making three-phase measurements the natural tendency is to adjust the voltage on each phase just before taking a reading. This, however, means that when the three-phase supply is slightly unbalanced the three readings are taken for three different voltages on the cable as a whole. It has been found a better practise to hold the voltage on one-phase constant during all the measurements on all phases and let the others remain slightly high or low in voltage. In this way, readings on the three phases correspond to a given condition though they will not correspond to a balanced condition.

Again, any unbalance in voltages means that there may be slight phase shifts sufficient to make it impossible to analyze the individual wattmeter readings and get any idea of conditions in the insulation of each of the three conductors forming the load. In fact, it is not unusual to get negative readings on one phase, though the total is positive in value.

Appendix V

The Three-Phase Wattmeter Switch

To determine the power loss and reactive volt-amperes in a three-phase test circuit, using one wattmeter, requires a large amount of switching. Fig. 10 shows the operations to be made. Points *X*, *Y* and *Z* must all connect to *G*, either directly or through the

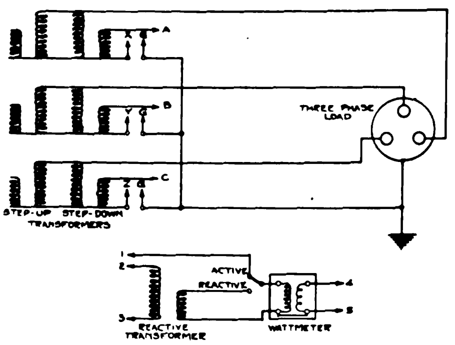

Fig. 10

current element of the wattmeter. With the current element of the wattmeter inserted between *X* and *G*, the potential element must connect to *A* and *X*, while the potential element for reactive volt-ampere measurements must connect to *B* and *C*. When the current element of the wattmeter is moved to connect between *Y* and *G*, the point *X* must again be connected to *G* and all the potential connections changed accordingly.

All of this switching with ordinary knife switches makes a very complicated and unwieldy arrangement. Accordingly, there has been developed at these Laboratories a simple-switching element which accomplishes in a single operation all of the necessary switching when changing from one phase to another. A diagrammatic view of this switch is shown in Fig. 11. The circles represent circular studs mounted in and insulated from the switch base. Connections are made to these studs as shown, the letters and numbers corresponding to those in Fig. 10. The upper or movable part of the

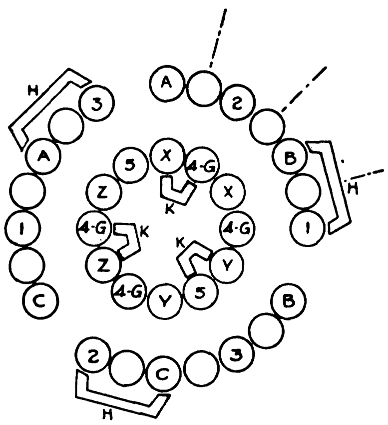

Fig. 11

switch rotates about the center and carries the spring contacts *H* and *K* which bear on the fixed studs. This switch in 60 deg. rotation provides correct connection of the wattmeter in each of the three phases.

Appendix VI

Shielding, Grounding, Etc.

In connection with all measurements made at high potential, shielding and guarding are important factors. In the three methods described in this paper, shielding is essential. All high-voltage parts, leads, etc., must be well shielded. All low potential wiring is best when done with metal-sheathed wire.

Shielding is most readily done when one side of the testing transformer and the transformer tank can be grounded. All the single-phase test equipments described in this paper are operated with one side of the testing transformer grounded. The grounding of the transformer and shielding protects the operator against contact with high-voltage parts.

As an additional protection to the operator, these testing equipments have been designed as "one-man sets," that is, they are built for complete operation by a single operator. All are equipped with safety switches which make it necessary for the operator to be in his place at the instrument table in order to put voltage on any of the equipment.

Abridgment of

Sag Calculations for Transmission Lines

BY H. B. DWIGHT[1]

Member, A. I. E. E.

Synopsis.—*A set of sag formulas is presented, in the form of convergent series which give accurately the results of the hyperbolic catenary formulas. The series are useful for calculating almost any practical transmission line span, long or short.*

Trial and error methods are not used. First, the sag or deflection is calculated for a given maximum tension in the cable. Then, changes in temperature corresponding to changes in deflection and loading are computed. This procedure is followed whether the supports are at equal heights or at unequal heights.

A formula is presented for the deflection from the line joining the supports, when the elevations are unequal. This is useful in sighting from tower to tower, as shown in Fig. 2.

A few examples are worked out and some derivations of formulas are given. In the last appendix instructions are given with regard to allowing for the change in weight per ft. with change in length of cable.

SAG calculations for transmission lines are frequently made by means of formulas based on the assumption that the curve of a cable in a span is a parabola. Formulas for the calculations are also published, which use the equation for the catenary, a curve so named because it is the shape of a suspended chain. This equation involves hyperbolic cosines.

In this article is presented a group of convergent series which will be found convenient and accurate for making sag calculations. Provided enough terms are computed, these give the results of the hyperbolic catenary formula as accurately as desired. Usually, two or three terms are all that are required. Since the series are convergent series derived from the expansions of hyperbolic functions, they can be said to be themselves hyperbolic formulas. The first term of the series is in many cases the same as the well-known parabolic formulas[2], the majority of which consist of only one term. The series herewith presented should therefore be easily understood and applied by those accustomed to the parabolic formulas.

The series moreover give directly and automatically the percentage error involved by using the parabolic formulas. Even where the latter have good accuracy, it is always worth while estimating the amount of their error in a given case. Often the worst feature of an approximate formula consists in the fact that the amount of its error is not indicated and remains unknown, so that in some more or less unusual case the error may be unexpectedly large. An approximate formula in the form of a convergent series is much safer to employ, since when the terms do not become smaller and smaller, the last one being negligibly small, it is obvious that the formula is not applicable to the case considered.

If, therefore, a formula is really the first term of a convergent series, it is practically always advisable to publish two or three terms of the series, so that the appropriateness of the formula for a given case may be quickly estimated.

The series are given in the form in which they can be most conveniently used for practical sag calculations. A few examples of their use are described, and in an appendix there is given the derivation of some of the series. The derivation of the others can be obtained by following the method of the examples given.

The description of the engineering problem is usually as follows: A certain maximum tension T is specified for a cable and it is desired to know what will be the sag corresponding to this tension under given conditions of temperature and wind and of ice loading. Further, it is desired to know what changes in temperature and tension correspond to given changes in sag or in loading. These results are required when the two ends of the span are supported at the same height or at unequal heights.

In preparing the formulas, the use of trial and error methods has been avoided. These involve more work than direct calculations, and have a greater liability of error. If values of temperature are assumed, such as 40 deg. or 60 deg., a trial and error process is required at some stage of the calculations. Accordingly, values of sag or tension are assumed, and temperatures are obtained by direct calculation.

This provides data for drawing a series of curves of sag plotted on temperature, separate curves being drawn for different lengths of span. These lengths of span may be the actual lengths for the transmission line being designed, or they may be even hundreds of ft., such as 200- 400- 600 ft., etc. In the latter case, new curves may be plotted from the first set, so as to show sag plotted against span, separate curves being plotted for specified temperatures such as 20 deg., 40 deg., 60 deg., etc., and for specified loadings.

These procedures do not involve trial and error processes. The drawing of the curves described above deals only with the final results, after temperatures have been calculated. This is not likely to produce errors in the same way as the use of curves for intermediate stages of the calculations.

Attention should be called to a paper by J. S. Martin,[3] containing a very complete table for calculating sags

when the supports are at equal heights. Formulas are given for using the data in the table when the supports are at unequal heights but it is stated that the precision is not as great as for the case of equal heights, on which the calculations for the tabulated data were based. A method of successive approximations is described for obtaining sags at specified temperatures. While this involves some work, it is an orderly procedure leading to the desired result.

Sag Formulas

It is to be particularly remembered that in the formulas in this paper, l represents a half span only.

Supports at Equal Heights

$$\text{Sag or deflection} = d = l\left[\frac{1}{2}\frac{w\,l}{T} + \frac{7}{24}\left(\frac{w\,l}{T}\right)^3 + \frac{241}{720}\left(\frac{w\,l}{T}\right)^5 \ldots\right] \text{ft.} \quad (1)$$

where $l = \frac{1}{2}$ span $= \frac{1}{2}$ horizontal distance between supports in ft.

T = tension in pounds, in cable at supports, where the tension is greatest.

w = resultant loading in lb. per ft. of cable. Note that $w^2 = v^2 + h^2$ where v is the vertical force per ft. acting on the cable due to gravity on the cable itself and on the ice covering, if any, and where h is the horizontal pressure in lb. per ft. due to wind. The deflection d is not vertically downward. The distance vertically downward by which the lowest point of the cable is lower than the supports is $\frac{v\,d}{w}$ ft.

When the deflection, d, is given,

$$T = w\,l\left[\frac{1}{2}\frac{l}{d} + \frac{7}{6}\frac{d}{l} - \frac{4}{45}\frac{d^3}{l^3} \ldots\right] \text{lb.} \quad (2)$$

The unstressed length of cable in the span is

$$L_u = 2\,l\left(1 + \frac{2}{3}\frac{d^2}{l^2} - \frac{14}{45}\frac{d^4}{l^4} + \frac{278}{945}\frac{d^6}{l^6} \ldots\right) - \frac{wl^2}{A\,E}\left(\frac{l}{d} + \frac{5}{3}\frac{d}{l} + \frac{4}{9}\frac{d^3}{l^3} \ldots\right) \text{ft.} \quad (3)$$

where A = area of cross section of cable, in square inches and E = modulus of elasticity in pounds per square inch.

The first line of formula (3) gives the actual perimeter of the catenary, and the second line gives the stretch in the conductor.

To find the changes in temperature, t, corresponding to changes in deflection, d, and loading, w, find values of L_u corresponding to certain values of d and w. The changes in L_u are due to temperature, if the cable is assumed fastened to rigid supports, and

$$t = \frac{L_u - L_{u0}}{a\,L_{u0}} \text{ deg.} \quad (4)$$

where t is the change in temperature,
L_{u0} = value of L_u at the lower temperature,
L_u = value of L_u at the higher temperature, and
a = temperature coefficient of expansion per degree. If a is specified per degree Fahrenheit, then t is in degrees Fahrenheit. Note that

$$L_u = L_{u0}\,(1 + a\,t) \text{ ft.} \quad (5)$$

When a is defined as the increase per degree above a certain temperature, then L_{u0} should be that temperature, in using equation (4) or (5).

Curves can be plotted of d against t. Different curves for different values of w can be plotted.

To find changes in load, w, corresponding to changes in d at a given temperature, insert values of d in equation (3). The value of w which will give the value of L_u for the given temperature, is obtained directly. L_u is given by equation (5).

Changes in temperature corresponding to changes in tension T are given by the following equation, and by equation (4).

$$L_u = 2\,l\left[1 + \frac{1}{6}\left(\frac{w\,l}{T}\right)^2 + \frac{7}{40}\left(\frac{w\,l}{T}\right)^4 + \frac{241}{1008}\left(\frac{w\,l}{T}\right)^6 \ldots\right] - \frac{2\,w\,l^2}{A\,E}\left[\frac{T}{w\,l} - \frac{1}{6}\frac{w\,l}{T} - \frac{7}{120}\left(\frac{w\,l}{T}\right)^3 \ldots\right] \text{ft.} \quad (6)$$

Curves of tension, T, against temperature, t, can be plotted.

Supports at Unequal Heights

It is usually desirable to find first a solution of the catenary for a given maximum tension T at the higher support where the tension is the greatest, as was done in the case when the supports were at equal heights. Then, changes in temperature, loading and tension can be calculated, corresponding to changes in deflection.

Let v and h be the vertical and horizontal forces per foot acting on the cable, as previously defined. Then, $w^2 = v^2 + h^2$. Let p be the vertical height by which one support is higher than the other and let $2\,l$ be the horizontal distance between the supports.

$$q = \frac{p\,w}{v} \text{ ft.} \quad (7)$$

$$2\,k = \sqrt{4\,l^2 - q^2 + p^2} = 2\,l - \frac{(q^2 - p^2)}{4\,l} - \frac{(q^2 - p^2)^2}{64\,l^3} \ldots \text{ft.} \quad (8)$$

These dimensions are shown in Fig. 1, which is drawn in the plane of the cable and not in a vertical plane.

If h, the wind pressure, is zero, then $q = p$ and $k = l$

Equation (8) is based on the fact that the square of the distance between the supports is equal to $4\,l^2 + p^2$ and to $4\,k^2 + q^2$.

Let

$$b = \frac{q}{2\,k} \tag{9}$$

$$\begin{aligned} m = {} & k\left(1 - b^2 + \frac{2}{3}\,b^4 - \frac{8}{15}\,b^6 \ldots\right) \\ & + \frac{T}{w}\left(b - \frac{2}{3}\,b^3 + \frac{8}{15}\,b^5 - \frac{16}{35}\,b^7 \ldots\right) \\ & - k\left(\frac{w\,k}{T}\right)\left(\frac{2}{3}\,b + 0 + \frac{2}{45}\,b^5 \ldots\right) \\ & - k\left(\frac{w\,k}{T}\right)^2\left(\frac{2}{3}\,b^2 + 0 \ldots\right) \\ & - k\left(\frac{w\,k}{T}\right)^3\left(\frac{16}{45}\,b + \frac{8}{9}\,b^3 \ldots\right) \text{ft.} \end{aligned} \tag{10}$$

The deflection, $d + q$, is found from equation (1) putting $l = m$.

The distance vertically downward from the upper support to the lowest point of the cable is $\dfrac{v\,(d + q)}{w}$ ft.

For finding the effect of changes of temperature and loading, it would be possible to assume different values of T and find values of m and d as shown above. However, it will be a little shorter to assume values of H the horizontal tension and find m from the following:

$$\begin{aligned} m = {} & k + \frac{H}{w}\left(b - \frac{1}{6}\,b^3 + \frac{3}{40}\,b^5 - \frac{5}{112}\,b^7 \ldots\right) \\ & - \frac{k}{6}\left(\frac{w\,k}{H}\right)\left(b - \frac{1}{2}\,b^3 + \frac{3}{8}\,b^5 \ldots\right) \\ & + \frac{k}{30}\left(\frac{w\,k}{H}\right)^3\left(\frac{7}{12}\,b - \frac{17}{24}\,b^3 \ldots\right) \text{ft.} \end{aligned} \tag{11}$$

The deflection in this case is found from

$$d = n\left[\frac{1}{2}\,\frac{w\,n}{H} + \frac{1}{24}\left(\frac{w\,n}{H}\right)^3 + \frac{1}{720}\left(\frac{w\,n}{H}\right)^5 \ldots\right] \text{ft.} \tag{12}$$

$$\text{where } n = 2\,k - m \text{ ft.} \tag{13}$$

After m, n and d are found, using either (10) or (11) for m, the unstressed length of cable is found by applying equation (3) to each part of the span separately, as follows:

$$\begin{aligned} L_u = {} & m\left[1 + \frac{2}{3}\left(\frac{d + q}{m}\right)^2 - \frac{14}{45}\left(\frac{d + q}{m}\right)^4 + \frac{278}{945}\left(\frac{d + q}{m}\right)^6 \ldots\right] \\ & - \frac{w\,m^2}{A\,E}\left[\frac{1}{2}\left(\frac{m}{d + q}\right) + \frac{5}{6}\left(\frac{d + q}{m}\right) + \frac{2}{9}\left(\frac{d + q}{m}\right)^3 \ldots\right] \\ & + n\left[1 + \frac{2}{3}\left(\frac{d}{n}\right)^2 - \frac{14}{45}\left(\frac{d}{n}\right)^4 + \frac{278}{945}\left(\frac{d}{n}\right)^6 \ldots\right] \\ & - \frac{w\,n^2}{A\,E}\left[\frac{1}{2}\,\frac{n}{d} + \frac{5}{6}\,\frac{d}{n} + \frac{2}{9}\left(\frac{d}{n}\right)^3 \ldots\right] \text{ft.} \end{aligned} \tag{14}$$

Curves for sag, temperature, loading and tension can now be drawn, as described for the case of support as equal heights. If a value of H has been assumed, the tension at each support can be found by applying equation (2) or (21) to each part of the span. The tension at a support is somewhat greater than H, and is greater at the higher support.

If there is no horizontal part of the curve between the two supports, then m is greater than $2\,k$, and n is a negative quantity. See equation (13).

Where a value of H is assumed, a table, not too condensed, of hyperbolic sines can be used with equation (18) to find m. However, this would not give a direct calculation for m in terms of T, such as is given by equation (10). If the difference in elevation of the supports is unusually great compared with the length of the span, the series may not converge rapidly enough, and a table of hyperbolic sines and cosines may be required. In such a case, trial and error methods may be necessary in order to obtain the desired results.

An illustration of this type of calculation is given in Example V. Since it is a trial and error method, different values of H must be assumed until a satisfactory value of T is obtained.

When the supports are at equal heights, values of H may be assumed and a table of hyperbolic sines and cosines used in a somewhat similar manner to Example V. This usually requires more work than to use the series. This is a trial and error method if one is working to a specified value of T. It may be necessary to do this if the series do not converge rapidly enough, as with an unusually large ratio of sag to span, but this is not likely to occur with practical transmission-line spans having supports at equal heights. One should also refer to the table by J. S. Martin[4].

Deflection from Line of Supports

After the location of the lowest point O, Figs. 1 and 2, and, therefore, the complete equation of the catenary

4. *Loc. Cit.*

for one set of conditions, have been found, it is possible to find by a direct calculation the vertical distance, PQ, from the line of the supports A and C to a tangent BD which is parallel to AC.

In Fig. 2, $PQ = AB = CD$, and the two latter distances may be measured on the towers and the line BD be used for sighting to determine the correct amount of sag to give the cable when stringing it. For

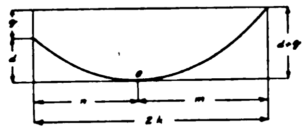

FIG. 1—SPAN WITH SUPPORTS AT UNEQUAL HEIGHTS

this purpose, assume that there is no wind or ice load, and so the cable hangs vertically. The calculation would be practically the same if wind load were included.

Let the equation of a line parallel to the line of the

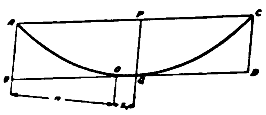

FIG. 2—DEFLECTION OF CABLE FROM LINE OF SUPPORTS

supports be $y = g\,x + f$ where g is known but where f is unknown. For this line, $\dfrac{d\,y}{d\,x} = g = \dfrac{p}{2\,l}$. The height of any point on the catenary above O is given by

$y = \dfrac{H}{w}\left(\cosh\dfrac{w\,x}{H} - 1\right)$. See Appendix I.

$$\frac{d\,y}{d\,x} = \sinh\frac{w\,x}{H}$$

If the line BD is tangent to the catenary at Q, which is the point (x_1, y_1),

$$\sinh\frac{w\,x_1}{H} = g$$

Then

$$\cosh\frac{w\,x_1}{H} = \sqrt{1 + g^2}$$

$$y_1 = \frac{H}{w}\left(\sqrt{1 + g^2} - 1\right) \qquad (15)$$

$$x_1 = \frac{H}{w}\sinh^{-1} g$$

$$= \frac{H}{w}\left(g - \frac{1}{2\times 3}g^3 + \frac{1\times 3}{2\times 4\times 5}g^5 - \frac{1\times 3\times 5}{2\times 4\times 6\times 7}g^7 + \ldots\right) \qquad (16)$$

Thus, numerical values of x_1 and y_1 can be obtained.

The height of P above O is $d + \dfrac{p\,(n + x_1)}{2\,l}$ and therefore,

$$P\,Q = A\,B = C\,D = d + \frac{p\,(n + x_1)}{2\,l} - y_1 \qquad (17)$$

all parts of which are known.

Example I. Find the difference in temperature for the following two sets of data for the same span:

$$2\,l = 800 \text{ ft.}$$

$$\frac{w\,l}{T} = 0.131\,28$$

$$\frac{w}{A\,E} = 0.000\,000\,757\,2$$

For the higher temperature, without wind or ice load,

$$\text{sag} = 23.176\,0 \text{ ft.}$$

$$\frac{w}{A\,E} = 0.000\,000\,297\,6$$

Temperature coefficient 0.000 0096

By formula (6),

$$\begin{aligned} L_{u0} &= 800\,(1 + 0.002\,872\,4 + 0.000\,051\,9 \\ &\qquad + 0.000\,001\,2\ .\ .\ .\ ) \\ &\quad - 800\,(0.002\,307\,0 - 0.000\,006\,6 \\ &\qquad + 0.000\,000\,04\ .\ .\ .\ ) \\ &= 800 \times 1.000\,625\,2. \end{aligned}$$

By formula (3),

$$\begin{aligned} L_u &= 800\,(1 + 0.002\,238\,1 - 0.000\,003\,5 \\ &\qquad + 0.000\,000\,01\ .\ .\ . \\ &\quad - 0.001\,027\,3 - 0.000\,005\,7 - 0.000\,000\,01\ .\ .\ .\ ) \\ &= 800 \times 1.001\,201\,6 \end{aligned}$$

By formula (4),

$$t = \frac{0.000\,576\,4}{0.000\,009\,6 \times 1.000\,625\,2} = 60.1 \text{ deg. fahr.}$$

This checks the result given in Mr. Martin's[5] paper.

Example II. Find the deflection for the following span[6]:

$2\,l = 2000$ ft.

Supports at equal heights.

$T = 70{,}000$ lb.

$w = 4.700$ lb. per ft.

$$\frac{w\,l}{T} = \frac{4.700 \times 1000}{70\,000} = 0.067143$$

$$\frac{l}{2}\left(\frac{w\,l}{T}\right) = 33.571$$

By equation (1), $d = 33.57 + 0.088 + 0.0005 = 33.66$ ft.

This agrees with the value of 33.6 ft. given in

5. Problem IV of the article by J. S. Martin, *Loc. Cit.*

6. Problem 2, p. 11, Transmission Line Design by F. K. Kirsten, 1923, Bulletin No. 17, University of Washington, Seattle, Wash

reference 6. It is seen that the series gives quickly and directly a precise solution of this problem, and the degree of precision of the calculation is indicated by the convergence of the series. The first term is the well-known parabolic formula.

Example III. Find the horizontal point for the following catenary[7]:

$2\,l = 2700$ ft.

Supports at unequal heights, $p = 179$ ft.

$T = 60\,587$ lb. at the higher support.

$h = 1.321$ lb. per ft.

$v = 2.870$ lb. per ft.

$w = 3.158$ lb. per ft.

$$q = \frac{p\,w}{v} = 197.0$$

$$2\,k = 2698.75$$

$$b = \frac{q}{2\,k} = 0.0730$$

By equation (**10**),

$m = 1342.2 + 1395.6 - 4.6 - 0.02 - 0.01 = 2733.2$ ft.

$n = 2698.7 - 2733.2 = -34.5$ ft.

The above paper gives $m = 2608.8$ ft. and $n = +91.2$ ft., but it neglects the fact that the cable lies in an oblique plane, and the dimension $p = 179$ ft. does not lie in that plane.

Example IV. Find the deflection for the following span[8]:

$2\,l = 4279$ ft.

Supports at unequal heights, $p = 185.5$ ft.

$T = 33000$ lb. at the higher support.

$h = 2.036$ lb. per ft.

$v = 2.623$ lb. per ft.

$w = 3.322$ lb. per ft.

$$q = \frac{p\,w}{v} = 235.0 \text{ ft.}$$

$$2\,k = 4276.57 \text{ ft.}$$

$$b = \frac{q}{2\,k} = 0.05495$$

By equation (**10**),

$m = 2132 + 545 - 17.0 - 0.2 - 0.4$

$= 2659$ ft.

By equation (**1**),

$d + q = 356 + 15 + 1$

$= 372$ ft.

The paper referred to above states that the deflection from the upper support is

$$9933.77 - 9615.44 = 318.33 \text{ ft.}$$

and that the deflection from the lower support is

$$9786.91 - 9615.44 = 171.47 \text{ ft.}$$

The difference between these deflections is 146.86 ft. which is less than the inequality in height of the supports, namely 185.5 ft. The difference of the deflections in the oblique plane should, however, be greater than 185.5 ft. In the appendix of the above paper, the equation $k_0 = k \cos\theta$ should be $k_0 = \dfrac{k}{\cos\theta}$, and formula (**3**) should be $k\left(\dfrac{1}{\cos\theta} - 1\right)$ instead of $k(\cos\theta - 1)$

$$\left[k = 185.5 \text{ ft. and } \cos\theta = \frac{2.623}{3.322}\right]$$

Example V. To illustrate the use of a table of hyperbolic sines and cosines,

Let $H = 31940$ in Example IV.

$$\frac{w\,k}{H} = \frac{3.322 \times 213\,8.28}{31940} = 0.222\,40$$

$$\sinh 0.222\,40 = 0.224\,24$$

$$\sinh \frac{w\,(k - n)}{H} = \frac{q\,w}{2\,H \times 0.224\,24}$$

$$= \frac{235.0 \times 3.322}{2 \times 31940 \times 0.224\,24}$$

$$= 0.054\,50$$

$$\frac{w\,(k - n)}{H} = 0.054\,47$$

$$n = 2138.28 - \frac{0.054\,47 \times 31940}{3.322}$$

$$= 1614.6 \text{ ft.}$$

$$m = 4276.57 - 1614.6 = 2662.0 \text{ ft.}$$

The value of T can now be calculated, and it will be slightly different from 33,000 since a value of H was assumed as part of the trial and error method.

The complete paper contains an appendix, here omitted, giving derivations of formulas.

LIGHTED STREETS

The lighting of public streets was originally a private undertaking, and the first city ordinance was passed in London in 1414, requiring all citizens to hang lamps before their doors at dark. Municipal street lighting originated in 1558 in Paris. Oil-burning lamps were used till 1813, when gas was adopted. In London electric street lighting is a development of the last forty years.

Discussion at Midwinter Convention

CARRYING CAPACITY OF 60-CYCLE BUSSES FOR HEAVY CURRENTS[1]

(LeClair)

New York, N. Y., February 9, 1926

H. B. Dwight: Usually it is found undesirable to place copper straps across lines of magnetic flux, but they should be placed parallel to the magnetic field as much as possible. Accordingly, where the phases are separated, I should suggest placing the straps parallel to the sides of an equilateral triangle, as in Fig. 1 of this discussion. If arrangement has not been tried out, it should be tested in comparison with the arrangements shown in Fig. 6 of the paper.

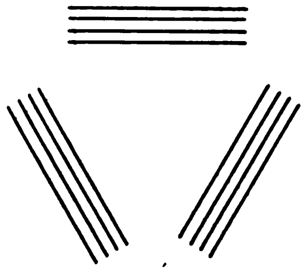

Fig. 1—Proposed Arrangement of Bus Bars

It is not always necessary to separate widely the conductors of different voltages. If the voltage is not over 250 volts, parallel straps connected + — + — etc., or A, B, C, A, B, C, etc., give extremely good results. In this way, currents up to 50,000 amperes at about 200 volts have been carried without trouble from skin effect, proximity effect, or reactance drop, as is well known in heavy electric-furnace work.

C. F. Wagner: The problem of current capacity of busses, by its very nature, is largely empirical. Mr. LeClair has contributed valuable experimental data to the general fund of knowledge on the subject.

I wish to question the statement made by Mr. LeClair on the fourth page of his paper which reads as follows: "In Mr. Wagner's article for single-phase busses he draws the curve from the outer edge to the center of the bar and assumes that the same condition holds from the center to the opposite edge of a bar. This is perfectly true in some cases but not at all true in others; and the electrical center, or the point of minimum current, in a bar may not be the physical center." While this statement is perfectly true, Mr. LeClair draws the inference that I would probably have made the same assumption, and, of course, been wrong, had I had a different set-up. The fact is that my assumption was correct for the particular case chosen, and for other cases in which the distribution was unsymmetrical I determined the distribution in the entire bar. Perhaps I am unjustified in interpreting the statement in this light and considering the matter merely one of an unfortunate choice of expression.

Regarding the use of magnetic steel for increasing the carrying capacity, the cut-and-try method of application does not appear to me to be an insurmountable difficulty. In connection with the magnetic balancers I should also suggest the use of radiating fins to carry away the iron loss in the balancers.

A. E. Kennelly: In the paper by Mr. LeClair, skin effect and proximity effect are fully referred to, but edge effect does not appear to be mentioned. If we take a flat strip of copper and allow it to carry direct current (the return conductor remote), we know, except for temperature variations, that the current density will be the same in all parts of the cross-section. However, when the strip carries an alternatng current, there may be negligible skin effect because the strip is thin. But the current density will not be uniform; it will tend to be much greater at the edges. That effect can be eliminated completely by bending up the strip edges so as to form a tube. The current density then becomes uniform everywhere, and the edge effect disappears.

That is a well known phenomenon and what we have in Mr. LeClair's paper is a mixture of edge effect and proximity effect. For example in the case of Fig. 2, you see that there is edge effect, but there are also proximity effects at the edges which are near to the other conductors. It is exaggerated, so to speak, by the vicinity of the neighboring conductors. But if the bus bars were removed or separated by a considerable distance, there would still be edge effect and the linear resistance of that conductor would be greater than that which would be obtained even though the skin effect were extremely small.

When the conductor is bent round, we tend to eradicate the edge effect, but we do not get rid of the proximity effect, and Curve 3, which represents Figure B, I think has an advantage in carrying capacity over Curves 1 and 2, corresponding to constructions where the edge effect is more pronounced. As Mr. LeClair has pointed out so well, it is very difficult to make measurements upon the resistance of bus bars owing to their size and cross-section. The linear resistance of the bars microhms per meter is so small that it is very often necessary, as he says, to infer the resistance from the temperature observations because where the point of resistance goes up including skin or edge effect, the temperature also will go up. On the other hand, we have to remember that all these effects of extra current density depend upon the resistivity and where the temperature goes up, the resistivity goes up too and modifies the effect. We thus get only an approximate measurement. The changes of temperatures involved will alter the distribution of current density.

S. W. Mauger: This subject began to interest the writer many years ago when rather exhaustive tests were made to determine a practicable and efficient method of carrying heavy currents. As Mr. LeClair states, the old standard of 1000 amperes per sq. in. and the practise of simply adding another parallel bar of copper to obtain increased capacity had become inadequate, especially for 60-cycle current. After trying many schemes, the writer suggested the plan now standard with the General Electric Company and referred to by Mr. LeClair in foot-note No. 5. One of the features of this scheme is the increased ventilation obtained and another is the so-called "box" arrangement which takes care of the skin effect. The first feature was very useful in carrying heavy d-c. currents and it was found that two sets of 4-in.-wide bars in vertical relation with 2-in. vertical space between them would carry at least as much current as one set of 10-in. bars, thereby saving 20 or more per cent of copper.

It may be inferred from Mr. LeClair's statement in the first paragraph on the fifth page of his paper that the General Electric Company scheme is suitable only for isolated phases and for currents not exceeding 7400 amperes at 60 cycles. Such an inference would be incorrect as the scheme allows the phases to be on close centers and by using wider bars with slightly more space between bars for increased ventilation, it has been possible to carry much greater currents than 7400 amperes, although this is as high as the published table goes. When there are long runs of bars for heavy a-c. current, transposition can be resorted to which overcomes any difficulty resulting from unequal distribution.

It would seem that with Mr. LeClair's proposed arrangement there would be difficulty in taking off connections from the bus bars except those of small capacity.

Mr. LeClair mentions the matter of permissible temperatures of bus bars. The rule of 30 deg. cent. rise is, of course, based on

1. A. I. E. E. Journal, January, 1926, p. 9.

an ambient temperature of 40 deg. cent. to give a maximum total of 70 deg. cent, the total being what we must have in mind. Naturally, if the ambient is lower, the rise may be higher, but for a standard rule, it is not safe to consider varying ambient temperatures. We must also remember that switching devices are designed on the basis of the A. I. E. E. Rule of 30 deg. cent. rise and bars connected to these devices must not have a higher temperature. Oxidation is much more rapid above 70 deg. cent. than below it, and it does not seem wise to consider an ambient of less than 40 deg. cent.

E. G. Bern (communicated after adjournment): In Mr. LeClair's contribution is a statement from which may be inferred that 7400 amperes is the feasible limit for a 60-cycle, three-phase bus with double-tier vertical laminations.

When dealing with currents of such magnitudes, the question of supporting the bus structure and its connections to withstand abnormal magnetic stresses usually demands a more liberal spacing of the bus phases. This is, of course, usually limited by available space, and by the permissible reactance, as mentioned

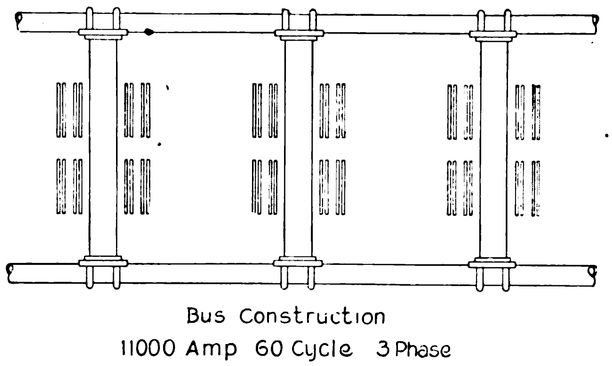

FIG. 2—BUS CONSTRUCTION, 10,000-AMPERE, 60-CYCLE, 3-PHASE

by Mr. LeClair. By properly proportioning the design, it has been found entirely practicable to use this construction for very much higher capacities without neglecting any of the above factors, and at the same time to make connections in a convenient manner. Fig. 2 herewith shows this construction successfully applied to a bus of 11,000-ampere capacity, which, however, should not be considered as the practical limit. Under some conditions a transposition scheme of equalizing the load in the different sections of the bus has worked out to good advantage without undue complications.

T. G. LeClair: At first thought it would seem undesirable to put copper straps across the lines of magnetic flux, and it would appear advisable to set up the three-phase bus with the bars arranged as shown in Fig. 3 herewith. However, after a

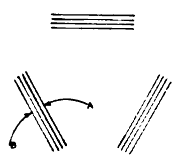

FIG. 3

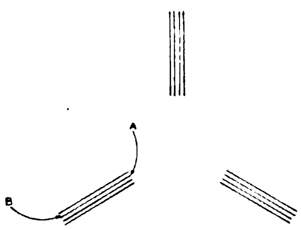

FIG. 4

careful examination of test results, we come to the conclusion that, with this arrangement, the ratio of currents at points A and B is practically the same as the ratio of currents at points A and B in Fig. 4 herewith. The particular case on which we have the most information from our test results is a bus consisting of four bars of 8-in. by ¼-in. copper, in arrangements which approximate Figs. 1 and 2. In this case, it appears that the current at point A is nearly three times the current at point B for either arrangement. This means that with the arrangements shown in Fig. 3 most of the current will be carried by the bar facing the center of the triangle and the other bars will carry very little. In Fig. 4, the outer edge of each of the bars will be carrying much less current than the inner edge, but they will reduce the temperature because they act in the nature of radiators, which is not the case with the unused copper of Fig. 3.

I do not wish to convey the impression that Mr. Wagner was making a mistaken assumption in his previous article. Some warning is, however, necessary because the majority of busses will be set up on an arrangement wherein the distribution of current will be unsymmetrical.

On the matter of balancing currents by means of magnetic balancers around the bars, there are two different points of view to take. One is that of the manufacturer of switchboards who has factory conditions to deal with and close contact with the men doing the work. In this case magnetic balancers may possibly be used to advantage. Out in the field we have different conditions, and usually the class of men doing the work is one unfamiliar with what is required. The contact between the engineer and the construction men is not so close, and the expense of the cut-and-try balancing is altogether out of reason. Some other method of balancing is much less expensive and more satisfactory for all cases.

Dr. Kennelly has brought up an important point in the use

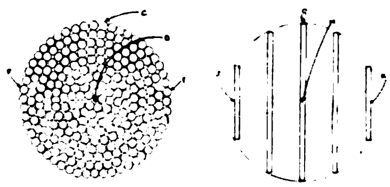

FIG. 5

of the terms "edge-effect" and "skin-effect." The difference in the significance of these terms should be made more clear. Fig. 5 herewith will probably explain my reasons for using the term skin-effect rather than the term edge-effect. This figure represents a single-phase circuit in which one of the busses is made up of laminated copper bars and the other of copper strands in the form of the cable. In the left-hand bus we all agree that due to skin-effect the current in the outer surface at C is much greater than the current at the center, D. Due to proximity effect the current at the point E is greater than the current at the point F, and by following the same reasoning in the right-hand bus, which, for the sake of clarity, I have made circular, we should still say that skin-effect is the cause of a greater current density at G than at H, and that proximity effect is the cause of the greater current density in bar J than in bar K. Now, if we arbitrarily take out the center bar of this bus and consider it separately we say that it is no longer skin-effect but edge-effect which causes the greater density at the point G than at point H. As I see it, edge-effect is a special application of the word skin-effect. Skin-effect should include any uneven distribution of the current in a bus or cable due to the flux created by the current in this bus, while proximity effect should include any uneven distribution caused by flux in an adjacent conductor. Regardless of the shape of the conductor, whether it be round, flat, or of any other shape, the uneven distribution due to the current in itself then causes skin-effect, and changing the shape changes the amount of this effect but does not change it from one type of effect to another. I do not wish to state that this is the best nomenclature to use for all cases, but I think it is time that we settle upon one definition by which we could all understand each other.

We did not make any test on an arrangement of bars exactly like that described by Mr. Mauger and by Mr. Bern, but it appears that they would have some trouble due to proximity

effect unless the busses were spaced a reasonable distance apart. Of course, so long as we can increase the spacing between phases and between individual bars of the phases, we may increase the carrying capacity indefinitely. When we come to the greater current, however, the weights of copper to be used become of considerable importance, and it becomes advisable to study carefully which arrangement will give the best copper economy. Perhaps it will pay to use a slightly more expensive support in order to use less copper. The type of construction illustrated in Mr. Bern's discussion is very interesting, but unfortunately no dimensions are shown with which to make comparisons of the copper economy to be obtained with this or another arrangement.

Mr. Mauger's points on the matter of permissible tempera-

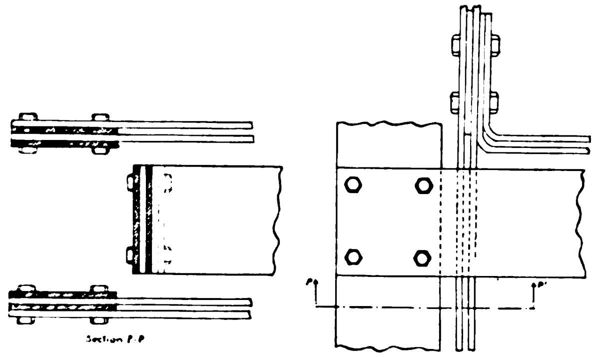

FIG. 6

ture rise are very well chosen. When a bus is to be connected to some switching device designed for a 30-deg. cent. rise, it is obvious that the bus copper must operate at the same, if not at a lower, temperature. It is impossible to make contacts for use in switching devices as good as a stationary bolted contact, and they must be protected. There are, however, a great many places where a bus is not connected to switching devices, for instance, between a transformer and rotary converter, and in such cases experience has shown that considerably higher temperatures may be maintained without any trouble from oxidation.

Fig. 6 herewith shows a sample top on a bus for high capacity. Tops in other directions can be made with equal ease.

REFRACTION OF SHORT RADIO WAVES IN THE UPPER ATMOSPHERE

(BAKER AND RICE)

NEW YORK, N. Y., FEBRUARY 9, 1926

A. E. Kennelly: The paper is very timely and interesting because so much attention has been drawn in recent months, not to say years, to the marvelous properties of very short waves. The paper makes a definite and very reasonable attempt to explain some of those properties. The direct wave dies out at a relatively short distance from the sending station and then nothing more is heard of it or received from it until it has traveled a relatively great distance. That phenomenon repeats itself at least once.

Here we are between certain rival theories of refraction and reflection from effects produced in the upper atmosphere at a distance at which we can only guess. It is very remarkable that we know so little. We are necessarily ill-informed concerning the conditions that exist in the atmosphere at a distance of, let us say, fifty-kilometers above our heads, while fifty kilometers along the ground we can cover in an automobile in an hour or less.

The wonderful thing is that we are able already to form opinions, such as are expressed in the paper, as to what does take place in that region above our heads which is so near and yet so far. The promise is very brilliant that we shall be able to learn from radio observations, in the not far-distant future, the electrical properties of the atmosphere at distances from ten to 100 or more kilometers above the earth, and it will be very surprising if the information thereby gained does not have a marked influence upon weather forecasts at least in the region up to twenty or thirty kilometers above the surface.

Personally, I think it is early yet to form hard and fast opinions or to make very definite conclusions as to just what these phenomena are. We know that there must be refraction. We know that there must be rotary polarization and we also know that there must be reflection. Probably all three of these things occur simultaneously. I think we must therefore retain an open mind for the present—until more information can be secured by observation.

W. B. Kouwenhoven: The author's conclusions are similar to those of Dr. J. Zenneck who published a paper on this subject in "Elektrotechnik und Maschinenbau", Vol. 43, p. 593 and 612, 1925. Dr. Zenneck concludes from observations that radio waves enter the upper atmosphere and that these waves may come back to earth at some distant point because of refraction.

Radio transmission takes place by means of ground waves and by means of waves that pass through the upper atmosphere. In the case of short waves the ground radiation is rapidly absorbed as pointed out by the authors, while the absorption is much less for long-wave transmission.

The electric field produced by a radio wave in the upper atmosphere sets the ionized particles in motion. In the case of long waves the mean free path of the ionized particle is short compared to the wave length, and collisions occur. The energy is therefore absorbed and very little if any of the wave is refracted back to earth. In the case of short waves the absorption is much less in the upper atmosphere, and the wave is refracted and reaches the earth again at some point distant from the transmitter.

M. I. Pupin: Mr. Einstein would probably say that you are wrong when you say that the wave can be propagated by a velocity greater than the velocity of light wave. What would you answer if he did object?

W. G. Baker: I think it is one of the cases of distinction between the velocity of a group of waves and the phase velocity.

With reference to the question of reflection versus refraction raised by Dr. Kennelly, I believe that most of the people who talk about reflection from the Kennelly-Heaviside layer use it as an approximation; they do not wish to bother with the complexity introduced by refraction. Actually the transition from the neutral to the ionized medium must be gradual, and will therefore not be sufficiently abrupt to produce appreciable reflection except on the very long wave lengths. Unless the ionization changes by a large amount in a distance comparable with the wave length of the radio wave no appreciable reflection can occur, but electron refraction may easily bend the wave back to earth.

Rotary polarization and other effects due to the action of the earth's magnetic field on the electron motion will require consideration in a complete theory of the propagation of radio waves as Dr. Kennelly has pointed out. We have evaded that phase of the question as well as we could by dealing only with the case of short waves where the earth's magnetic field cannot have much effect. There is a certain resonance frequency of the electrons produced by the earth's magnetic field which corresponds to a wave length of about 214 meters. If we are working well above that frequency the effect of the earth's magnetic field on the motion of the electrons can be neglected without serious error.

We wish to thank Dr. Kouwenhoven for calling our attention to Dr. Zenneck's paper, and we are interested to hear that his conclusions concerning the propagation of short radio waves are similar to ours.

Recently there has been a good deal of surmising, on the part of radio men, as to the height of the ionized medium. Obviously we cannot speak of the height of the actual medium since we do not know where to say it begins, where the maximum is, or where

it ends. The effective height of the layer as judged by a sharp reflection theory will, of course, vary with the wave length, distance between transmitter and receiver, etc. On short waves we require a relatively large amount of ionization to bend the ray back to earth. Therefore the ray will penetrate deep into the ionized medium before it returns to earth. Here the apparent height of the layer as judged on the reflection theory may be very great. On longer waves a smaller ionization density is sufficient to bend the same ray back to earth so that the depth of penetration will be less and the apparent height of the medium will be lower than that estimated from the short-wave experiments. A further difference is brought in by the effect of the earth's magnetic field.

CIPHER PRINTING TELEGRAPH SYSTEMS[1]

(VERNAM)

NEW YORK, N. Y., FEBRUARY 9, 1926

L. F. Morehouse: This work on the development of arrangements for secretly transmitting telegrams was done during the War under the direction of Mr. Gherardi. The problem was to see if a simple and effective means that would be entirely secret could be devised for handling telegraph business. The method used should be such that an enemy could not decipher the messages even if he could capture the mechanism used, thoroughly understand its operation, and obtain contact with the line circuits.

A large number of systems were studied. Of the many suggestions made, the most promising were set up and tested out in the laboratory. Various schemes for breaking up the dots and dashes were proposed, but in the last analysis all were found to be unsatisfactory. We found in studying this problem that many methods had been devised. Where mechanical devices were used, they involved, sooner or later, a repetition of the key. If there is such a repetition, the messages can be deciphered and the real secrecy has disappeared.

Printing telegraph methods were found to be more promising. The key in the form of a paper tape or resulting from the combination of two such tapes can be made as long as desired without repetitions with the result that the cipher becomes impossible to break. For ordinary business purposes, however, a simpler cipher using a key that might repeat at infrequent intervals would be entirely practical and sufficiently secret.

P. W. Evans: None of the present military codes or ciphers offers complete satisfaction in its security, speed or simplicity. The Signal Corps of the Army will appreciate any assistance or suggestions which may be offered on this important phase of our national defense problem.

CONCLUDING STUDY OF VENTILATION OF TURBO-ALTERNATORS MULTIPLE PATH RADIAL SYSTEM[2]

(FECHHEIMER AND PENNEY)

NEW YORK, N. Y., FEBRUARY 9, 1926

S. L. Henderson: This paper covers the results of a considerable amount of experimental work done subsequent to the papers written in 1924 by Mr. Fechheimer and Mr. Bratt. As the later tests were made on stationary models, the constants could be determined more accurately than on a moving model, and the accuracy of the equations is demonstrated in the comparison between tests and calculations as given in Figs. 13 and 14. The results of this work are being used in the design of turbine generators with considerable practical benefit. On one design, in particular, it was possible to shorten the machine considerably through the use of these equations.

The choice of the number of vents and the division of these vents into intake and outlet zones is thus made relatively simple. The number of vents is determined by the velocity of air required in the radial vents to obtain satisfactory cooling on the sides of the vent spaces. The number of vents is also determined by the width of the iron package between vents which can be allowed without having an excessive temperature drop in the package. Several trials, as in most questions of design, must be made in order to obtain the best proportions. After the number of vents has been decided upon, the division of these vents into intake and outlet zones can be carried out through the use of the equations in this paper.

A NEW WAVE-SHAPE FACTOR AND METER[1]

(DOGGETT, HEIM, AND WHITE)

NEW YORK, N. Y., FEBRUARY 11, 1926

J. J. Smith: When considering the effect of harmonics, it is perhaps well to divide them into different classes: (1) those which may give rise to resonant conditions or large circulating currents on the power circuit, (2) those which may give rise to telephone interference, (3) those which may give rise to radio interference, (4) those which may give rise to any other type of trouble that may be discovered. Let us consider, for instance, the case of telephone interference, as somewhat similar remarks will apply to other types of interference. In the telephone-interference-factor meter an attempt was made to weight the various harmonics in accordance with the experimental data available as to the interfering effect of each harmonic. A special type of network was designed to do this, and the impedance characteristics of such a network, which is used in the telephone-interference-factor meter, can be varied, within certain limits at least, to correspond with any new data which may show that it is desirable to weight the harmonics differently. In the method suggested by Messrs. Doggett, Heim, and White, no such adjustment is possible.

The method proposed may also be compared with a method such as the use of the telephone-interference-factor meter by noting the ratio between the maximum and minimum values obtained on machines in actual operation. The T. I. Fs. given on the machines of Table I of the 1919 Report of the A. I. E. E. Subcommittee on Wave Shape Standards vary from 11 to 550, while the ratios given by Messrs. Doggett, Heim and White vary from 2.746 to 3.724, giving a ratio of 50 to 1 with one method and 1.35 to 1 with the other.

It is well to remember that direct-current and other types of machines produce harmonics, and that it is undesirable to have a wave-shape meter which will apply to three-phase systems only. Also, in certain cases of telephone interference which have occurred on systems with the neutral grounded, it is the wave shape from line to neutral and not from line to line which is of interest.

I would like to inquire if the authors found any difficulty in making measurements on systems on which there were large variations in load. In making measurements of harmonics on such systems we have found that the magnitude of the harmonics varied with the load over short periods of time (in the order of one or two seconds). I wonder if fluctuations of this nature would not make it impossible to get a consistent curve from which to pick the maximum as in Fig. 5.

It may be well to consider the first paragraph of the paper by briefly considering what accuracy may be obtained in analyzing a wave obtained with the oscillograph. Let us assume an oscillogram has a maximum ordinate of 2 in. and that the line is of average thickness, which, in order to get a good film, may be 1/20 in. or less. Using a wave micrometer ruled in fortieths of an inch there is no reason why the values of the ordinates should not be measured to within half of one division or 1/80 of an inch. This is an error of 1 in 160 or let us say 0.7 per cent. As the probability is that all these errors will not be in the same direction, it would appear more proper to take, perhaps, half of this, or say 0.35 per cent, as the probable error in measuring

1. A. I. E. E. JOURNAL, February, 1926, p. 131.

the oscillograms. Using this figure the maximum deviation in the first case quoted by the authors from the *Revue Générale de l'Electricité* should have been between the limits 2.6 per cent and 1.9 per cent or the maximum value is in excess of the average by about 15 per cent of the average value, and correspondingly less in the other case.

The large discrepancies quoted by the authors may be due to the inherent difficulty in superposing the equivalent sine wave of equal length in such a manner as to give the least difference, as required by A. I. E. E. Standards, 1922, No. 3274. It would be impossible, however, to explain them without making a detailed study of the calculations which were made in each case. Also, a comparison of the T. I. Fs. calculated from oscillograms and those taken direct with the T. I. F. given in the 1919 Report of the Subcommittee on Wave Shape of the A. I. E. E. Standards Committee, will show that the large discrepancies quoted by the authors cannot be the general rule. Furthermore, it should be remembered that by using a filter or some such device for stopping off the fundamental, a very much higher degree of accuracy in measuring harmonics may be obtained with the oscillograph.

F. K. Brainard: It is generally recognized that sine waves in a-c. apparatus are desirable and since commercial alternators frequently have voltage waves which differ considerably from sines, it would be highly desirable to have a wave-form factor which could be easily determined and which would be a measure of the detrimental effect resulting from a distorted wave. Various factors have been suggested including the following: (a) form factor, (b) peak factor, (c) telephone-interference factor, (d) differential distortion factor, (e) integral distortion factor, (f) curve factor, and (g) harmonic factor. None of these appears to be entirely satisfactory, partly because the detrimental effect of a distorted wave depends upon the trouble under discussion and partly because some of the above factors are not readily measured. If telephone interference is being considered, the telephone-interference factor is undoubtedly the proper criterion to apply, but if the core loss of transformers is under consideration or the dielectric strength of insulating material is being measured, it is quite obvious that some other factor should be used.

While this new factor gives the greatest weight to the seventh harmonic, there is not an exceedingly great variation in weight given between any of the harmonics, and in this respect it resembles the "harmonic factor" which is defined by Bedell as the ratio of the effective value of the harmonics to the effective value of the fundamental, but is superior to it in that it is very easily measured, although it is applicable to three-phase circuits only. Possibly an Institute rule using both the telephone-interference factor and this new factor specifying limiting values of both, would be desirable. In that case, the telephone-interference factor would limit possible telephone interference and this new factor would limit other troubles due to the presence of the lower harmonics.

The authors are to be complimented for the development of a wave-shape factor which gives promise of being a valuable one. The question now seems to be the determination of the value of this factor as a criterion for the comparison of voltage waves.

C. W. Bates: The paper contains a satisfactory analysis of the proposed method which should give reasonably correct values for the harmonics present, when the conditions are ideal. The paper does not, however, contain any investigation of the errors which may arise from such sources as the use of voltmeters containing some inductance, condensers whose loss is not negligible, and unbalanced line voltages. The entire theory of the proposed method rests on the assumption that when no harmonics are present the potential of the neutral point of the circuit used is displaced to such a point that the voltmeter readings have the ratio of 3.732. This is true only when both voltmeters are absolutely non-inductive, the condensers are absolutely without loss, and the voltages of the three phases are absolutely equal.

If it is assumed that each voltmeter has an inductance L in addition to its resistance R and that the condenser has a loss represented by its equivalent series resistance r in addition to its capacity c the ratio of the voltages indicated with exactly balanced three-phase line voltages will be approximately equal to $3.732 \left[1 + \sqrt{3} \left(\frac{\omega L}{R} - r \omega c \right) \right]$ when $R = \frac{1}{\omega c}$. The fractional error is then equal to $\sqrt{3} \left(\frac{\omega L}{R} - r \omega c \right)$ or practically equal to the difference of the angles of defect (from the ideal) multiplied by $\sqrt{3}$. The approximation in this result is due only to considering that the angles of defect are equal to their respective sines and tangents and that the cosines are equal to unity. These approximations are entirely justifiable for any voltmeters or condensers whose use could be considered.

The importance of these errors may be judged by considering two examples:

Voltmeters: $R = 1000$ ohms, $L = 53$ millihenries

$$\frac{\omega L}{R} = .02 \text{ at 60 cycles,}$$

$$\text{Condenser: } \frac{1}{\omega c} \text{ 1000 ohms, } r = 50 \text{ ohms}$$

$r \omega c = 0.05$ (3 deg. approximately)

The fractional error in the ratio will be equal to $\sqrt{3}$ (0.02 − 0.05) = − 0.052 or − 5.2 per cent. (By the exact expression this is 4.9 per cent, thus justifying the approximate expression given for the error). If the voltmeter inductance is 5.3 millihenries as may occur in the best modern dynamometer voltmeters and the condenser phase angle is 17 min. as might be found in a good mica condenser, each angle of defect is one-tenth the former value and the error is 0.52 per cent. Even this error is quite appreciable in the calculation of the method shown in the paper. Fortunately the errors due to inductance and to condenser loss are opposite in sign and therefore, by a suitable adjustment, they may be made to neutralize each other.

The error due to unbalanced three-phase voltage may be much greater and moreover varies continually with line-voltage fluctuations. This error may be readily analyzed by the use of the symetrical coordinates developed by C. L. Fortescue. By this method any unbalanced system of three-phase voltages is resolved into two balanced systems of opposite phase rotation. Since the direction of shift of the potential of the neutral point is determined by the phase sequence, it may be readily appreciated that voltages of opposite phase sequence simultaneously impressed will not result in the ideal ratio of voltmeters of 3.732, even if no harmonics are present.

The analysis of this error is too complicated to be presented in a brief discussion but the results of the analysis may be illustrated numerically. Let m be the degree of unbalance expressed by the ratio of the negative-sequence voltage to the positive-sequence voltage. This is roughly equal to the greatest deviation of any one of the three voltages from the mean. The error due to unbalance will depend not only on this ratio but on the phase angle between the two oppositely rotating components noted with reference to any instant. Accordingly the limits of the error are given in the first four lines of the tabulated illustrations below. Since the authors state that any small error due to voltage unbalance may be eliminated by stepping the line terminals around the circuit terminals and averaging the results obtained by the use of each of the three connections, a comparison of the error of this average is given also, in the last four lines.

Two numerical examples are given in the table, one corresponding to a 10 per cent unbalance such as would result from

voltages of 90, 105, and 105, or to 91.3, 100, and 108.7, each of these groups being approximately respective phase voltages which would result in a 10 per cent negative-sequence voltage, the difference in line voltages resulting in a different phase angle. The other example is based on a 1 per cent unbalance due for example to voltages of 99, 100.5 and 100.5. In general the unbalance will be between these limits, as the first corresponds to very poor service voltage while the second will be difficult to maintain even under laboratory conditions. From the figures given in the table it is seen that the results of a single pair of readings are entirely untrustworthy even with very well balanced voltages, and that good balance is necessary in order to secure reliable results, even if the terminals are stepped around. It may be noted that the average ratio is always high.

Negative-sequence Voltage m	10 Per cent	1 Per cent
Maximum ratio of readings	6.04	3.882
Error of maximum, per cent	62	4.0
Minimum ratio of readings	2.68	3.593
Error of minimum, per cent	29	3.7
Maximum average ratio	4.022	3.7335
Error of maximum average ratio, per cent	7.8	0.043
Minimum average ratio	3.755	3.7333
Error of minimum average, per cent	0.6	0.033

The formula from which these results were calculated is included without derivation, for the sake of completeness.

Ratio of voltmeter readings

$$= \sqrt{\frac{A + \frac{m^2}{A} + 2\,m\cos(60° + \alpha)}{\frac{1}{A} + A\,m^2 + 2\,m\cos(60° - \alpha)}}$$

$$= A\sqrt{\frac{1 + \frac{m^2}{A^2} + \frac{2\,m}{A}\cos(60° + \alpha)}{1 + A^2 m^2 + 2\,A\,m\cos(60° - \alpha)}}$$

where

A = 3.732,

m = ratio of negative - to positive-sequence components,

α = angle between components in the reference phase which is taken to be that across which the voltmeters are connected.

L. A. Doggett: We have been very pleased to have Mr. Bates attack this problem from his own angle of approach and not only check our (2 plus $\sqrt{3}$) but also show us the method of eliminating the errors due to the inductance of the voltmeters and the resistance of the condenser.

So far as the effect of unbalance is concerned we would like to submit for comparison with Mr. Bates' figures the data for one test. With balanced voltages the wave-shape factor for a certain wave was 3.693. With the same wave and with voltages of 100, 97, and 97.5, the wave-shape factors, as the terminals of the wave-shape meter were stepped around, were 3.54, 3.95, and 3.60, averaging 3.697. Experimental study of the effect of unbalanced voltages indicated that useful results were obtainable up to 2 per cent unbalance.

Mr. Smith has brought out some of the contrasts between the telephone-interference-factor meter and the present wave-shape meter. He has also covered the question of the accuracy obtainable from oscillograms. As the wave-shape meter is not a telephone-interference-factor meter, no discussion is devoted to their comparisons. Mr. Smith has described what might be called the utmost accuracy obtainable from oscillograms. The results cited in our paper are considered fair samples of every-day accuracy obtainable. As to the effect of load pulsations, we find no difficulty in getting results while undergraduate laboratory work is in full swing.

In concluding the discussion, it should be pointed out that the instrument, made accurate in the manner described by Mr. Bates, is particularly well adapted to shop testing of three-phase alternators, which have three exactly balanced voltages. Like the telephone-interference-factor meter, this meter has its distinctive characteristic. While the T. I. F. meter penalizes the 17th and 19th harmonics for 60-cycle alternators, the present wave-shape meter penalizes harmonics of phase rotation opposite to that of the fundamental.

Lastly, we find this meter admirably suited for showing and recording changes in alternator wave shape as the character of the load changes. Functioning thus, the wave-shape meter has brought to our attention some rather remarkable facts.

THEORY OF THE AUTOVALVE ARRESTER[1]

(Slepian)

New York, N. Y., February 9, 1926

K. B. McEachron: The comparison made by Dr Slepian between the energy to be handled by the valve-type arrester and the arc-resistance type for equal protection is important. With the arc type, if the flow of system energy following the impulse is not to be excessive, it is necessary to employ considerable series resistance with the result that the arrester's ability to discharge the impulse is seriously impaired. To prevent system current from following the discharge of an impulse through an arrester, it is necessary that the voltage across the arrester, as the impulse ceases, be equal to or greater than the system crest voltage. The modern valve-type arresters are designed to operate on this principle.

In his discussion of the glow discharge Dr. Slepian states that with an electrode spacing of slightly less than 0.001 cm. a voltage of 350 volts is required to maintain the glow. The theory given states that the voltage required to start the glow is less than 400 volts and the current density in the glow is about 10 amperes per sq. cm. until the disk area is covered, after which the gap voltage increases with increasing current becoming 387½ volts with a current density of 25 amperes per sq. cm. Since the effective area inside the mica spacer is of the order of 15 sq. cm. the voltage drop across the air-gap based on Dr. Slepian's figures should be constant at 350 volts with a current of 150 amperes or less increasing to 387½ volts with a current of 375 amperes.

A series of tests covering a period of two years made on these disks have led the writer to suspect that the voltage across the air gap during a discharge was not maintained at approximately 350 volts during a discharge.

It was found, for instance, that with 280 volts (crest) applied that current would follow an impulse so timed as to strike near the crest of the 60-cycle wave. This seemed to indicate a voltage much less than 350 volts following the impulse since 280 volts was sufficient to cause current flow. With steep-wave-front impulses, applied voltages as high as 1200 volts were indicated across a single gap which showed that the breakdown might be more than three times the glow voltage.

More recently we have been able, using the cathode-ray oscillograph to determine accurately the volt-ampere characteristic of disks with spacers even when the discharge lasted but a few millionths of a second. With this oscillograph photographs have been taken showing wave fronts of less than a microsecond duration with oscillations whose frequencies were of the order of 100,000,000 cycles showing so plainly that their wave shape could be determined. With this instrument, three volt-ampere curves were taken on a stack of sixteen disks with fifteen mica spacers, each different volt-ampere curve having a different crest value of current. The disks were then coated with copper on each side and stacked up without the spacers and a volt-ampere curve taken from which the voltage drop in the disks was determined for any particular value of current. By this means it was

1. A. I. E. E. Journal, January, 1926, p. 3.

found that the average resistance of a single disk was 3 ohms at 10 amperes and 2 ohms with 150 amperes flowing. With 450 amperes the average disk resistance is 1.1 ohms.

The volt-ampere curves of the air gaps for the three different currents were obtained by subtracting the disk volt-ampere curves from the disk-plus-spacer volt-ampere curves. Using Dr. Slepian's statement that with current densities less than 10 amperes per sq. cm. that the area of discharge is proportional to current it is clear that the disk voltage is constant for currents less than 150 amperes, and is numerically equal to the voltage when 150 amperes is flowing through the disk. Using this method of calculation of disk resistance the curves shown in Fig. 1 herewith were obtained. The theoretical glow voltage according to Dr. Slepian is also given. It is to be noticed that a voltage of from 600 to 700 volts was required to start current flow through the gap with the particular wave front used. As

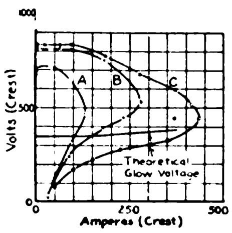

Fig. 1

the current increases to about five amperes the voltage rises to 710, 810, and 830 respectively for the three current waves. With both of the higher current curves the voltage tends to remain constant at about 800, decreasing, however, for currents in excess of about 100 amperes. When the current begins to decrease the voltage falls off until at low current values the voltage is less than 100 volts which seems to indicate the formation of an arc. It must be remembered that the shape of these curves is dependent on the amount of resistance material involved at any particular current and if the author's theory of the spreading of the discharge is incorrect then the values of resistance which have been used are not correct. The volt-ampere curve obtained across the stack of disks is a true characteristic, and the volt-ampere relations in the gap will be those given if the proper correction has been made for the resistance of the disks.

If the discharge had the characteristics attributed to it by Dr. Slepian, the voltage across the gap would be represented by 350 volts plus the additional 37½ volts as the current increased to 375 amperes. With decreasing current the relation between the voltage and the current should still be the same so that the volt-ampere curve will be represented by a single line instead of the loop which is actually found.

With all three volt-ampere curves shown, the applied voltage rose to the gap breakdown voltage in a time close to one microsecond, while the respective currents rose to their crest values in 20, 35, and 48 microseconds. From these results it would seem that the time-current relations are important in the gap discharge for with the same current, different voltages were found on each of the three different volt-ampere curves. I believe that several factors have been left out of this formula.

I have been unable to check the curves shown in Fig. 9 of this paper using this formula (corrected). I should appreciate an explanation of the formula by Dr. Slepian, and should like to know how it is plotted to get these curves.

The effect of rate of voltage application on the breakdown of the gap was not discussed by Dr. Slepian but, as with any phenomena involving ionization, time is required for the gap to reach breakdown conditions. The results of tests on sixteen disks with mica spacers are as follows:

Time-Voltage Relations of Autovalve Gap

Time to Rise to Breakdown	Gap Voltage (Crest)
1.5 microseconds	665 volts
2.5 "	530 "
30 "	390 "
60 cycles	400 " variable

These results show that in discussing the characteristics of the discharge between two electrodes as in the autovalve gap, the effect of time both before the discharge begins and after it has started cannot be neglected.

The test results given in this discussion show that discharges having quite different volt-ampere characteristics from those given by Dr. Slepian are actually to be found in the air gap between autovalve disks. These results are useful not only in connection with the theory of the glow discharge but also are of importance when applied to the actual arrester performance in service. So far as I know these results are the first to be actually obtained under impulse conditions where the time, voltage, and current relations are fully determined.

On the sixth page Dr, Slepian gives a formula for the determination of the temperature rise at the surface of a disk when a certain amount of energy is liberated at the disk surface.

J. Slepian: The paper which I have presented was written over a year ago, and in that time there have been some important additions to our knowledge of the theory of the autovalve arrester which I would like to mention briefly before taking up Mr. McEachron's welcome account of his researches.

The autovalve arrester in its functioning depends on the well established fact that a heavy current discharge between electrodes of resistivity of the order of ten ohms per cu. cm. remains in a high-voltage form for a relatively long time, whereas such a discharge between metal electrodes changes into a low-voltage form within less than a microsecond after its initiation. These two forms of discharge have long been known as glow and arc, respectively, and their properties, at least in the steady state, are fairly well known. As stated in the paper, it is generally believed that the arc discharge takes place when the cathode is hot enough for thermionic emission. Then, a difficulty arises because it appears that the density of energy input into a metal cathode surface from a glow is not great enough to heat a spot on the electrode to a high temperature in a time so short as a microsecond. It seems necessary to assume almost immediate convergence of current into some spot before that spot has become hot. The resistivity of the autovalve electrodes opposes this concentrating tendency.

Until recently, it was assumed that this concentration of current took place at inhomogeneities of the metal surface. Now, however, a new theory has been developed which seems to fit the facts quantitatively, and eliminates the need for inhomogeneities to start the current concentration. This theory is that in the heavy-current glow discharge at atmospheric pressure, the air immediately adjacent to the cathode becomes heated almost immediately to a temperature high enough for thermal ionization, and with metal electrodes this thermal ionization causes the glow to be unstable and to converge into an arc. Further particulars may be found in a paper which appeared in the *Journal* of the Franklin Institute for January, 1926.

Another advance which has been made is in our understanding of the factors which determine the rate of spreading of the discharge in the autovalve gap from its point of initial breakdown next to the mica spacer. We have known, from our tests on the protective valve of the arrester, that this spreading is very rapid, but now we have information as to the influence of electrode spacing, and also know how this factor influences the volt-ampere characteristic for impulse voltages.

The points of lowest breakdown in the autovalve gap are next to the mica spacer, the breakdown voltage there being usually less than 400 volts. If the mica spacer were not there,

the breakdown voltage would be much higher, depending on the width of the gap, and for a 5-mil gap would be about 1000 volts. Now it is clear, that with such a 5-mil autovalve gap, if 1000 volts is applied, the discharge does not need to start at the mica, but the gap will break down at all points together. For such a voltage then, the discharge may be said to spread instantly over the electrode surfaces. For a lower voltage the rate of spreading while still very fast will no longer be instantaneous. Since the rate of spreading of the discharge determines the rate at which

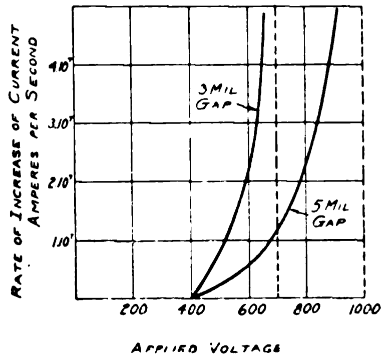

FIG. 2

the discharge current builds up in the arrester, we may expect a curve such as in Fig. 2 herewith, with an asymptote at 1000 volts for the 5-mil gap. For a 3-mil gap the asymptote will be at about 700 volts.

When an impulse current is sent through an autovalve gap, the total voltage while the current is increasing is determined by the rate at which the current is increasing. If the current is increasing slowly, the voltage will be about 400, but if the current builds up instantly the total voltage may be 1000 for

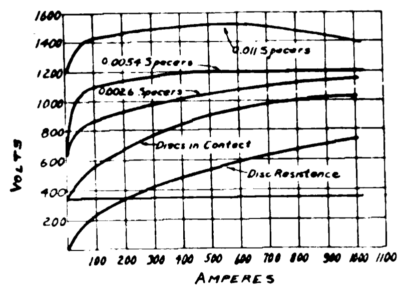

FIG. 3

the 5-mil gap and 700 for the 3-mil gap. The total voltage here includes not only the discharge voltage but also the resistance drop through the disks.

These ideas are largely the result of a study by G. F. Harrington of the impulse volt-ampere characteristics of arresters with different sizes of spacers. These were taken by determining the maximum volts and maximum amperes in a discharge by means of sphere gaps. Fig. 3 shows results obtained. It is evident that with the disks in contact, the voltage obtained corresponds to the steady-state glow, but that when the disks are separated, there is an additional rise in voltage which is necessary to cause the discharge to spread sufficiently rapidly over the disk faces.

The lowest curve in Fig. 3 is the impulse volt-ampere curve of the disk resistance, obtained by copper-plating both faces of each disk and stacking them in series. On subtracting this curve from the others in Fig. 3 we get the curves of Fig. 4. Disks in contact give a curve which lies very close to the 350-volt line, but with increasing thickness of spacer, the voltage on impulsive discharge increases rapidly.

Coming now to the results which Mr. McEachron has obtained with the cathode-ray oscillograph and which are shown in his Fig. 1, we see that as regards the magnitudes of the voltage for increasing current, there is general agreement with the results obtained by Harrington and shown in Figs. 2 and 3. It would seem from these curves that Mr. McEachron used spacers at least 0.005 in. thick, which is the upper limit for spacer thickness tolerated in the commercial autovalve arrester. With thinner spacers even better performance would be obtained. However, I believe that because of the incorrect value which he has taken for the ohmic drop through the disks, the lower parts of Mr. McEachron's curves are in error.

First of all, the current density in the discharge is only approximately 10 amperes per sq. cm., and may actually be somewhat larger. It is probably also not an absolute constant, and may vary with slight changes in disk composition. But

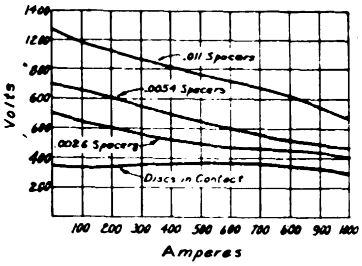

FIG. 4

taking this value, although the whole disk area is not uniformly covered for current less than 150 amperes, when the current decreases to less than this value, the discharge breaks up into a large number of very small spots which are distributed over the whole face of the disk. With this distribution of discharge the ohmic resistance is that of the whole disk and not that of only part of the disk as Mr. McEachron figured. Therefore I have redrawn Mr. McEachron's curves with the correct ohmic drop in Fig. 5.

These curves show three more or less distinct portions—first there is a higher voltage part where the current is spreading over the disk face. Then comes a drop to approximately 350

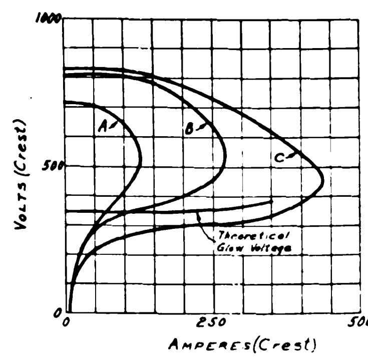

FIG. 5

volts, where the curve tends to become horizontal. The slight departure from 350 volts is readily accounted for due to uncertainty in the disk resistance, since the current distribution in plated disks is different from that with discharge, and also uncertainty in the proper value to take for the current density. Lastly there is a low-voltage part during the last 50 amperes of the discharge, which is undoubtedly due to vague contacts and lining up of particles in the gap by the intense field.

These vague contacts which follow an intense discharge explain Mr. McEachron's finding a current flow at 280 volts. By raising the resistivity of the disks this leakage current may be

reduced to as small a value as we please. In the commercial autovalve arrester this leakage is usually not detectable on an ordinary oscillograph.

Mr. McEachron's experiments on the impulse breakdown of autovalve gaps are very interesting. They show that the voltage rises to less than double for very fast discharges. When the voltage reaches the value corresponding to the gap length without distortion due to the spacer, we should expect speeds equal to that of a sphere gap.

The last point which Mr. McEachron raises is as to the correctness of Fig. 9 in the paper. The formula is incorrectly printed and should read,

$$T = \frac{W\sqrt{t}}{4.18\sqrt{\pi\, k\, c\, \delta}}$$

Taking $t = 0.001$ sec., $k = 0.016$, $\delta = 2.0$, $c = 0.185$ and $W = 3500$, gives $T = 194$ deg. which agrees with the curve of Fig. 9.

IONIZATION STUDIES IN PAPER-INSULATED CABLES—I[1]

(Dawes and Hoover)

New York, N. Y., February 8, 1926

A. E. Kennelly: Turning to the paper by Dawes and Hoover, it seems to me that the great force of that contribution lies in the fact that a bridge has been developed which employs a vibration galvanometer, with all the delicacy and precision that the vibration galvanometer affords, so that instead of having to employ a relatively great length of cable dielectric for test, it is sufficient to have only, say, a couple of meters, provided that the particular couple of meters shall represent fairly well, the whole length of a cable under consideration.

E. W. Davis: One of the most important problems which confronts the manufacturer of high-voltage cables is that of dielectric loss, its fundamental cause and its relation to the other necessary properties of a well designed cable.

The papers by Messrs. Dawes & Hoover adds one more to the numerous theories concerning the nature of dielectric loss and power factor. Unfortunately many of the papers published to date, while excellent mathematical treatises on the subject, are not founded on any scientific research work or based on data of many tests. In fact, outside of a very few isolated experiments, many of the theories cannot be checked at all.

In a recent paper presented before the British Institution of Electrical Engineers, "Dielectric Problems of High-Voltage Cable", by Percy Dunsheath, an attempt is made to connect dielectric loss with dielectric absorption, dielectric hysterisis, and dielectric conduction. Much data and many curves are given to substantiate the theory and there is included a rather unique discussion of the relation between a-c. and d-c. losses.

The paper by Dunsheath and the paper by Dawes & Hoover offer two widely divergent theories for dielectric loss, and yet both of them contain features that may be readily checked.

Fig. 1 herewith shows a few typical power factor-voltage curves that we have obtained with various impregnating compounds and at various temperatures. These tests were made in a special oil testing condenser and with a high-voltage, 60-cycle bridge. The curves are quite similar to those shown in the Dawes-Hoover paper, one in particular showing the peculiar knee found at high temperatures by these investigators.

Fig. 2 shows two curves calculated by means of the formula (17) of the Dawes & Hoover paper. By slightly varying the assumptions as to location and dimensions of the air films, both types of curves are obtained. One interpretation of such tests would indicate that compound ordinarily contains more or less air distributed through it and exhibits the same phenomena of restricted ionization as laminated insulation even though the barrier effect of the paper is not present. Another phenomenon exhibited by cable insulation, but not discussed by Dawes & Hoover, is the V curve of power factor and voltage. Numerous samples tested show a decrease of power factor with increasing voltage and then as higher stresses are reached, a rapid increase.

In built-up insulation, there are invariably minute air films. The loss through these films depends upon the conduction

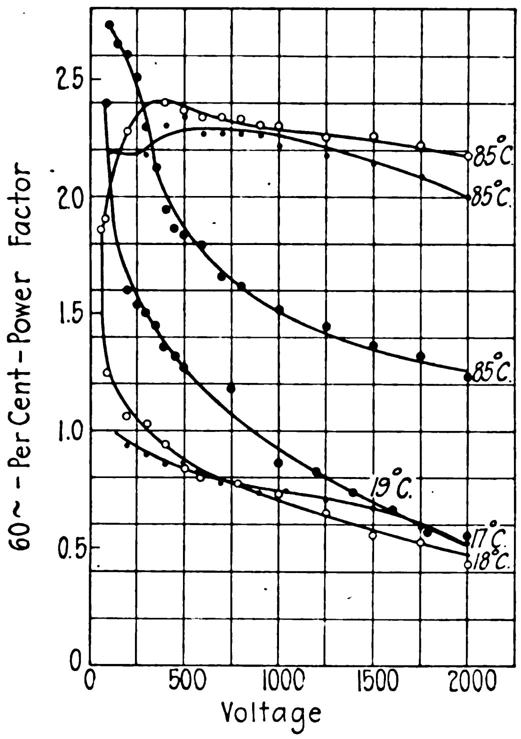

Fig. 1—Power Factor Versus Voltage Various Impregnating Compounds

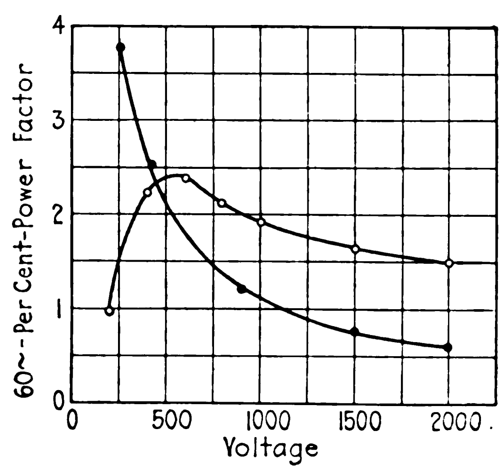

Fig. 2—Calculated Power Factor-Voltage Curves Impregnating Compounds

through and conduction around the film along the paper. The conduction loss at low stresses would follow ohm's law and at high voltages would depend upon the degree of ionic saturation or ionization. If we consider a very low-pressure air film between two paper tapes, the full ionic saturation would be reached at a very low stress and, therefore, the leakage current would not increase directly with the voltage. The dielectric loss, therefore, would not increase directly with the voltage and this would mean a decrease of power factor with increasing stress. This phenomenon holds until a point is reached where ionization

1. A. I. E. E. Journal, April, 1926, p. 337.

of the higher-pressure air in the insulation is complete. If the ionization took place at the same voltage for a large majority of the air films, we would expect a sharp increase of power factor. It is possible that the ionization point for various films may differ so much that a gradual rather than a sharp increase of power factor occurs. This effect is of course governed by the relative amount of air to insulation, the average pressure of these air films and the leakage characteristic of the paper insulation. We should not expect to find this phenomenon in a cable the paper insulation of which had quite high leakage characteristics.

Tests on Impregnated-Paper Sheets. Power-factor tests on sheets of vacuum-dried and impregnated paper were made with a high-voltage bridge in order to check the previous conclu-

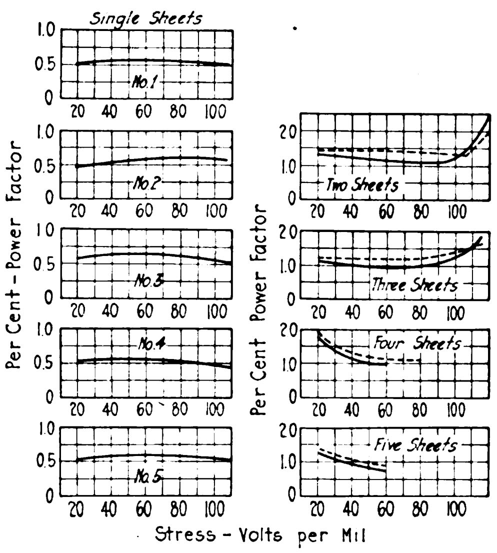

FIG. 3—SIXTY-CYCLE POWER FACTOR VERSUS VOLTAGE IMPREGNATED-PAPER SHEETS. DOTTED CURVES ARE RESULTS OF TESTS WITH PRESSURE ON UPPER ELECTRODE

sions. It was thought that tests on single sheets of paper in very close contact with the electrodes would show the characteristics of the paper insulation itself. Then, using more than one sheet, tests could be made with air films between.

The curves in Fig. 3 show the results of these tests.

In no instance was a *V* curve obtained with a single sheet of paper. Two and three sheets of paper, when placed loosely together and tested, gave decided *V* curves of both the gradual and the sharp type. With three and four sheets of paper, sufficient stress could not be obtained with the voltage available to reach the critical point in the power-factor curve but the start of the *V* curve was obtained in each instance. The application of pressure to the upper electrode when testing multiple sheets changes the character of the curves very much. In Fig. 3, when two sheets are tested under pressure, the *V* curve is partially eliminated and the voltage at which ionization takes place is increased. With three sheets under pressure, the *V* curve is eliminated completely. In the case of four and five sheets, sufficient pressure was not applied to remove the *V* curve completely but the dotted curves shown seem to indicate the tendency for this to take place.

W. A. Del Mar: The paper by Dawes and Hoover contains a wealth of experimental material which requires considerable detailed study, and it is difficult to comment upon the results without knowing more about the materials worked upon. For instance, cables impregnated with different types of compounds would probably show different characteristic curves. I think that the value of the paper would be increased very much if information were given regarding the type of compound used in the cables for which curves are given. For instance, whether the compounds are solid or liquid at the temperatures at which the experiments were made, and so on.

I notice that most of the experiments, if not all of them, were made with single-conductor cables. Some rather interesting work which Mr. Hanson has been doing and also some which has been done in England and recorded in the current Journal of the Institution of Electrical Engineers, England, indicates that in three-conductor cables, a large proportion of the loss which occurs at the higher voltages occurs in the fillers, and if the fillers are omitted or replaced by some material which has not the same characteristics as the ordinary paper crepe, those losses can practically be eliminated and the ionization curve,—that is to say, the voltage-power factor curve,—becomes virtually a horizontal line between stresses of 20 volts and 100 volts per mil, which are about the limits in Fig. 5 of the paper.

It would therefore seem that the work which the authors have done needs to be somewhat amplified by an analysis of just the parts of the cable in which the principal losses occur, at the different voltages. It is possible that by such an analysis, steps could be taken to reduce these losses at the higher voltages.

Anyone who has done any laboratory work of this kind will appreciate the immense amount of painstaking, careful work that Prof. Dawes and Mr. Hoover have done in this paper. Nevertheless, I am not entirely convinced that their curves represent insulation characteristics to the exclusion of test-apparatus idiosyncrasies. When, however, you look at the curves and compute the number of experimental points they have made, the work appears to be really prodigious, and even if some corrections should have to be made, the authors are to be congratulated upon their results.

R. W. Atkinson: I have been interested in bridge measurements ever since I became connected with the cable industry, and last year published in the *Electric Journal* a description of the method we are now using and gave a brief description of it in a discussion before the Institute. The bridge that has been shown tonight, and the one I described are about as different in general construction and circuit as two instruments both of the bridge type could well be and yet serve the same purpose. Yet I am interested to note that they both have certain fundamental characteristics and attain final results equivalent in many respects.

The sensitivity of the two types is nearly the same, so far as I can judge from the figures given in the paper, and the voltage across the measuring parts of the bridges is comparable. These are fundamental parts of the whole problem of precision measurements of dielectric losses. As Prof. Dawes has pointed out, it is very desirable indeed to have the voltage drop across the resistance in series with the measured condenser very low so that no difficulty will be experienced from the effects of the capacitance to ground of the detector and certain other parts of the circuit. His instrument and mine are closely alike in this respect and have a very much lower drop than in the case of any other dielectric-loss-measuring device of comparable sensitivity that has been described.

Some fundamental differences between the two bridges are these:—My bridge uses an a-c. galvanometer as a detector; Prof. Dawes uses a vibration galvanometer with vacuum-tube amplifiers to get the same result.

The vibration galvanometer requires accurate frequency which is not always convenient where a commercial circuit supplies the power. The a-c. galvanometer requires an auxiliary source of current to supply the field at the same frequency as that supplying the measured condenser.

An advantage of our bridge over most other devices for measuring dielectric loss is that it is so arranged that when balance is obtained, the power factor may be read directly from the dials.

There is one difference between the two instruments, which is a very important one and is in favor of the a-c. galvanometer

type. In using the vibration galvanometer, it is necessary to secure a very accurate capacity balance before the power-factor balance can be obtained. With the a-c. galvanometer type the bridge is first made sensitive almost entirely to capacity and then made sensitive almost entirely to the power factor, by changing the relation of the field so that the capacity balance does not have to be made nearly so accurately as it would otherwise have to be. This is very significant because it permits measurements to be made much more rapidly than with the other type.

E. S. Lee: With reference to the Dawes-Hoover paper, I think there are several things of great interest to those who have to work with cables and make measurements thereon. In the first place, we find that we have one more method added to the already long list and large number of different means by which we measure dielectric power loss. This is a bridge method. As Mr. Atkinson has said, about a year ago he described his bridge, and just a year ago from this same platform we were told of work which had been done with the Schering bridge, which work has been carried on for this past year with great success.

Prof. Dawes says: "On one occasion after completing a 60-cycle test, we found that the 25-cycle losses were greater than the 60-cycle losses even though sufficient time had been allowed for the cable to reach constant conditions." Such conditions are not new to those who are making these measurements continually. Also, if you will observe the curves of his Figs. 11, 13, and 16 you will observe "humps" which might be looked upon as indication of error. But Prof. Dawes has stated that they have checked those portions and they find those humps should be there in the curves. These also are found by other observers.

Thus, we are glad to find that as new investigators take up this work, their results are in agreement with what has been found in factory testing and experimentation.

I want to call attention to one point, which may not be necessary, particularly to those who are familiar with the work, but I think it is quite necessary, particularly for those who are not so familiar with the work. Some reference was made to the fact that these are characteristic curves, and I grant you that they are, except I would call to your attention that the largest portion of these curves is outside of the operating range; that is, the curves in Figs. 8 to 16 are for a cable which we would say would be normally rated at 12 kv. If you will look along the abscissas or on the curves for 12 kv., you will notice that within that value the dielectric power loss is quite small; the power factor is very low, and the change in these values is small. It is well beyond this voltage that the changes occur. In the present-day cable, the same conditions exist. We have to go beyond the operating values, considerably, in order to get these changes.

There is one other thing to which I would like to call attention: when I first looked at these curves, I thought the change in capacitance was enormous, but if you will note the scales, you will find it is not. It is only about 5 per cent. The change in the power factor is of the order of 300 to 400 per cent; the change in dielectric power loss is of the order of about 3000 per cent. So one has to observe these scales carefully in order to obtain correct conceptions. The explanation offered by the authors for the shape of these curves is good and of value, though if tests are made on cables with different treating compounds and with liquid fillers, it will be found that these same curves are not characteristic for those cables but that another set of characteristic curves will be obtained. Their shape likewise has to be explained.

I believe we are largely forgetting what power factor is. We talk about it quite a bit. I believe I am right when I say that it is the ratio between the dielectric power loss and the product of the voltage and the current. In other words, the variations in these three quantities govern the variation of the power factor; therefore, a discussion of the variation of power factor must include the variation of these factors. It is really the dielectric power loss that we are interested in. If we talk in terms of power factor, then our results become more directly comparable without regard to volume of the dielectric, but I think if we remember that the loss varies quite nearly as the square of the voltage, that the capacitance does not change greatly, hence current is proportional to voltage, we can work out the ratio of these factors and see just about how the power factor will vary. If air ionization is present, however, conditions are quite different from those when no ionization exists, particularly since the dielectric power loss varies at a faster rate than the square of the voltage.

I was interested in the agreement between calculated results and measured results, and the statement also that if we knew the constants, we could very readily calculate. I think that is true but the constants are often difficult to determine.

W. B. Kouwenhoven: The authors state that the air condenser that they employed in their bridge had a phase angle. In measurements that I have made with the Schering bridge I have never been able to detect any phase angle in the air condenser used. Slight errors, however, may creep in due to insufficient shielding of the leads and apparatus, and these will cause discrepancies which are usually assigned to a phase angle in the air condenser. Proper shielding will often eliminate these errors.

In some work that I have been doing with Dr. Whitehead

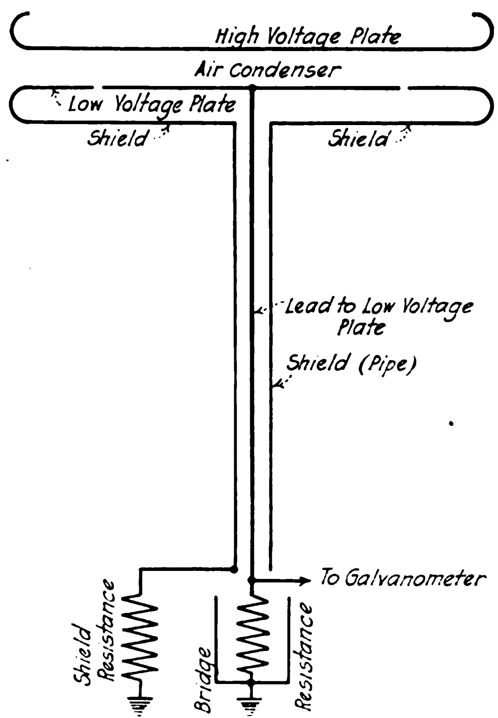

FIG. 4

we have found it necessary to shield the air condenser and its leads as shown in Fig. 4 herewith, which shows the air condenser side of a high-voltage bridge. The pipe shield on the lead to the low-voltage plate of the air condenser must be maintained at the same voltage as the lead otherwise charging currents between this lead and its shield will introduce errors in the results. Any change that is made in the bridge resistance in series with the condenser lead must be accompanied by a proportional change in the resistance in series with the shield, otherwise an error will be produced in the phase angle as determined in the bridge. The shielding of the specimens should be carried out in a similar manner.

In measuring losses at high voltages with the Schering bridge

or with the quadrant electrometer at Johns Hopkins University we have followed the practise of determining the accuracy of the apparatus. In making this check we first measure the loss in a specimen and then insert a known non-inductive resistance in series with the specimen and measure the loss again. We determine the current in the specimen circuit and calculate the loss in the added resistance. If the apparatus is functioning correctly the loss in the added resistance should equal the difference between the first and second loss measurements.

W. F. Davidson: I desire to call attention to certain limitations of the method used by Dawes and Hoover and, indeed, by most other investigators. We are dealing here with a composite insulation which is stressed to such values that ionization reaches considerable proportions. As a consequence, such "constants" as capacity and resistance cease to be true constants and not only vary with the effective value of the impressed voltage but even vary cyclically. Whitehead, Peek, and others have called attention to the distorted current wave of corona, which is merely another way of stating that the capacity and resistance are not constant.

Under these conditions the observed data, and with them the computed data, will depend upon the method of measurement—a wattmeter method will give one result and bridge methods other results.

To illustrate this, assume that the impressed voltage is not distorted in any way and that we have a reference "no-loss" circuit as well as the circuit containing the test specimen. The voltage and the two currents may be written in the form:

$e = E\,[A_1 \sin \omega t + B_1 \cos \omega t]$

$i_1 = I_1\,[a_1 \sin \omega t + b_1 \cos \omega t]$

$i_2 = I_2\,[\alpha_2 \sin \omega t + \beta_2 \cos \omega t + \ldots \alpha_n \sin n \omega t + \beta_n \cos n \omega t]$

and

$A_1^2 + B_1^2 = 1, \quad a_1^2 + b_1^2 = 1, \quad \alpha_2^2 + \beta_2^2 + \ldots \alpha_n^2 + \beta_n^2 = 1$

In the test circuit the true power will be

$$W = \frac{E\,I_2}{2}(A_1\,\alpha_2 + B_1\,\beta_2)$$

since the over-tones in the current wave have no corresponding element in the voltage wave and hence do not contribute toward the average power.

If the measurements be made with a wattmeter (dynamometer or electrostatic) with an ammeter and voltmeter, the observed and computed results will be:

Potential difference $= E/\sqrt{2}$ r. m. s. volts

Current $= I_2/\sqrt{2}$ r. m. s. amperes

Power $= \dfrac{E\,I_2}{2}(A_1\,\alpha_2 + B_1\,\beta_2)$ watts

Power factor $= A_1\,\alpha_2 + B_1\,\beta_2$

Resistance $= \dfrac{E}{I_2}(A_1\,\alpha_2 + B_1\,\beta_2)$

Capacity $= \dfrac{I_2}{E\,\omega\,\sqrt{1 - (A_1\,\alpha_2 + B_1\,\beta_2)^2}}$

If the measurements be made with a bridge using a tuned vibration galvanometer or a dynamometer with fields excited at the fundamental frequency, the results would be as follows if the measured voltage and standard capacity are used:

Potential difference $= E/\sqrt{2}$ r. m. s. volts

Current $= \dfrac{I_2}{\sqrt{2}}\sqrt{\alpha_2^2 + \beta_2^2}$

Power $= \dfrac{E\,I_2}{2}(A_1\,\alpha_2 + B_1\,\beta_2)$

Power factor $= \dfrac{A_2\,\alpha_2 + B_1\,\beta_2}{\sqrt{\alpha_2^2 + \beta_2^2}}$

Resistance $= \dfrac{E}{I_2}\,\dfrac{A_1\,\alpha_2 + B_1\,\beta_2}{\sqrt{\alpha_2^2 + \beta_2^2}}$

Capacity $= \dfrac{I_2\,(\alpha_2^2 + \beta_2^2)}{E\,\omega\,.\,\sqrt{(\alpha_2^2 + \beta_2^2) - (A_1\,\alpha_2 + B_1\,\beta_2)^2}}$

These results depend on the fact that the bridge will only balance the fundamental component of i_2 against the reference circuit. In a bridge measurement, securing balance with a hot-wire or other untuned detector, it will be impossible to secure an exact balance and the observed values will differ in many points from those above.

In closing, I should like to suggest that we have reached a point in our researches where it seems essential that we consider instantaneous value $\dfrac{\partial E}{\partial I}$ and not average values. Fortunately the means for doing this are already at our disposal in the cathode-ray oscillograph. The JOURNAL of the Institution of Electrical Engineers for November, 1925, contains three excellent papers dealing with this powerful tool of the modern investigator into dielectric phenomena.

G. B. Shanklin: Several years ago I made a special study of the subject of "ionization in cables," and as a co-author submitted some of the findings in Institute papers. Our work dealt largely with "cause and effect" from a practical standpoint. No quantitative nor qualitative analysis was attempted. The work, in conjunction with that of contemporary workers, resulted in recognition of the cause and importance of ionization in cables and established methods of eliminating or reducing it. Recent advancement in the voltage rating of cables is based on the principles demonstrated by this early work.

A more expert and systematic study by qualified physicists and research engineers familiar with the electron theory has long been needed. This excellent paper by Messrs. Dawes and Hoover represents, I hope, a beginning which will result in eventually establishing the theory of ionization in cables on a firm quantitative basis.

Their present results are not only a distinct advancement but are in good agreement with our previous work, as far as it went. By using a length of ordinary impregnated paper cable with a special loose sheath, we obtained curves very similar to those in Fig. 7 of the paper. The curves were not, as theirs are, subject to accurate analysis, for ionization of the large air space directly under the loose sheath was obscured by simultaneous ionization through the thickness of paper insulation. The use of a model cable sample enabled them to obtain much more accurate data.

Change or shifting of ionization curves, as shown in Fig. 9, is, as they state, a function of time. I agree that residual or free ions, after the voltage is reduced, are the main contributing cause of this, but do not agree that absorption or higher internal temperature plays an important part. Instead, there appears to be a factor discovered by J. J. Thomson and called "ionization pressure," which is important. When the gas spaces are first ionized, this "ionization pressure" pushes the softened compound back, resulting either temporarily or permanently in enlarged gas spaces. A particular cable might operate indefinitely at normal voltage without ionization, but if a momentary over-voltage, such as produced by a switching surge is applied, ionization might persist for some time after the voltage drops back to normal. This is, in effect, exactly the same characteristic shown in Fig. 9.

The irregular shape of the first section of the high temperature-power factor curves, as shown by Figs. 11 and 13, is, I have believed for some time, due to the liquid nature of the compound. Some form of ionic conduction through this liquid is apparently responsible, for these peculiar shapes are obtained only with liquid filling compounds. I have seen the same type of curves obtained at room temperature when a thin oil is used for impregnation.

On the fourteenth page the authors make the statement: "It has been recognized for some time past that, although the paper itself has lower dielectric strength than the impregnating compound, the dielectric strength of the cable is increased by using paper in combination with compound." This statement is misleading. They evidently mean that cellulose fiber in paper form and in combination with air has less strength than when in combination with compound. This is evident since compound has greater strength than air. Actually, cellulose in pure form is an excellent insulator, and this is why paper, acting as a barrier, improves the dielectric strength of the compound.

Their theory of the formation of tree designs seems very plausible. Certainly, it must be due to tangential stresses along and between the surfaces of the paper wrappings. The high-frequency nature of this discharge is also well established. It might be pointed out that impregnated paper insulation has something like one-tenth the dielectric strength longitudinally between surfaces of wrappings, that it has radially or perpendicular to these surfaces. The absence of fiber barriers in this direction accounts for this.

It is sincerely hoped that the authors will continue their valuable work to a final conclusion.

J. B. Whitehead: We have had some difficulties which Professor Dawes doesn't mention, and which I hope he hasn't had. There are also some that he has had which we have not. Dr. Kouwenhoven has called attention to one of our greatest difficulties, that is, the screening of the test electrode and maintaining the guard electrode at exactly the same potential. On our Schering bridge, we found we could get power-factor measurements in the same range that Professor Dawes is working, that would differ by 50 to 100 per cent simply by a variation in the resistance in the tail of the guard circuit. I presume he has solved that difficulty, or perhaps his bridge is not so sensitive to it as our own.

As to the phase difference of his air condenser, I am astonished at the value that he finds. We have found nothing to indicate such a difference in our condenser. We have split it into two halves, put one-half in each side of the bridge, and have added small resistances in the tail circuit of the side we are measuring, thus checking by successive increments of power factor, to see whether there is any initial value of phase difference. We have not detected any, and I hope that Professor Dawes, will tell us what he consideres to be the source or cause of the phase difference he finds. In this connection I have the following references to phase difference in air condensers:

Giebe and Zickner, in the Archive fur Elektrotechnik, find that in standard air condensers of the Reichsanstalt no phase difference can be detected by methods measuring the same to an accuracy of from one to two seconds of arc. These are small air condensers, and I think the maximum voltage upon them was about 300 volts, and the measurements were directed only at the possibility of a phase difference due to the normal ionization of the air. This is the only source that I can think of for a phase difference, unless, one has actual point discharges between the plates of the condenser, in which case you could get ionization losses of any description. I assume that Professor Dawes' condenser was free from error of this type.

E. Möller also finds that radium rays and copious brush discharge in the neighborhood of an air condenser have no effect on its phase difference, but he is working at frequencies up to 180,000 and above, so perhaps his figures cannot be taken.

C. H. Willis who is working in my laboratory has computed the value of the phase difference due to the normal ionization in the air. This was for a condenser of our dimensions, in which the space separation up to about 35,000 or 40,000 volts is two inches. The ratio of charging current to conduction current is based on the normal velocity of ions in the air, and the potential gradient and the frequency, and so on, a very simple calculation. The value of the phase difference in this case works out to be 4×10^{-6}. This is far below the figures which Messrs. Dawes and Hoover have given and indicates a negligible phase difference.

I do not feel that it is necessary to invoke the structure of the atom in explanation of the behavior of this type of insulation. I believe that the change in the power factor, as it rises beyond the ionization point, can be accounted for by the saturated conditions in these air layers, if it be remembered that this ionization is extinguished at every half wave, as the voltage goes down below the critical value. We have every reason to suppose that at such frequencies as we are using here, there is complete extinction, every half wave. As a consequence there arises the question of the recombination of the ions, and I think it is clearly evident from the very interesting and beautiful experiments on the artificial cable with an air layer, that there is a normal saturated condition due to a limited air area, beyond which you do not get any further ionization and therefore no further loss, as you go on up in voltage.

Another thing that we have to note here is that there are two possible sources of loss in ionization: one due to the actual process of ionization itself, the actual collision or the knocking apart of component parts, and then on top of that such conductivity as exists due to the passage of the ions across the air space. I think it is very easy to picture a saturated condition and if we have that, it is very easy to see that as the voltage curve goes up, the power factor may reach a maximum.

I also was particularly interested in the difference between the ascending and descending curves, and I would like to ask whether these curves repeat themselves accurately. Nothing has been said here about the effect of the presence of ionization on the cable structure itself. It is a most powerful destructive agent. If you have any layer in which there is active ionization going on, I wouldn't say that it would remain in the same condition for more than a few seconds. I think it probable that much of the trouble in cable insulation is due to the fact that it is rapidly destroyed as soon as we let ionization start. I venture the prediction that in a few years' time we are going to see some curves of this kind which will be flat, and when you do that, and not until you do, will you have cable that will be satisfactory. When ionization goes on, the cable is going to pieces, and it seems to me that it is only a question of thorough and complete impregnation. If we can get that, I don't see how we can fail to straighten these curves out and get rid of the principal cause of this trouble.

C. A. Adams: Referring to the destructive effect of internal corona, I have photomicrographs which show the fusing by corona of mica laminae in the insulation of a 25,000-kv-a. turbo alternator. There was in this case conclusive evidence of what might be called a "corona blast," namely the reaction of the corona currents on the magnetic field due to the load currents in the armature conductors; the corona current being perpendicular to the magnetic field.

C. L. Dawes: Mr. Del Mar requested some more data on the cable. These are in the hands of the Committee. We have the cable numbered and I believe we know the manufacturer, but we we do not know the compound. He states that he hopes we determine in which part of the cable the loss occurs. At the present time we are analyzing the cable layer by layer, finite thicknesses from the center out, those thicknesses being so small that they are practically surfaces. Our one source of error is that we must assume that the air spaces are equally distributed through the insulation. If that is not true, our work obviously will be in error.

He states that we have done a lot of work and determined so many experimental points. I merely wish to add to that and state that these are just a few representative data. There wouldn't be room in an ordinary journal to include all the curves which we could put in.

We are very glad Mr. Lee pointed out the fact that we were

carrying the operating range of the cable above the ordinary operating voltage. It is necessary to do this, however, in order to study the phenomena. We are studying ionization itself, and we are not attempting to obtain the ordinary commercial curves which have been published or which are readily obtainable in many manufacturers' laboratories.

Mr. Davidson brought out the fact that the current is distorted by the variable factors in the circuit. We have had that in mind for some time, and Mr. Hoover and I have discussed the possibility of obtaining oscillograms of the charging current through the cable. That is one of the details which we have set aside until a more opportune time comes to make an investigation in that particular direction. I will state, however, that in some of our early experiments the man who was doing the work at that time told me that he had obtained a power factor of something like 0.1 per cent. I questioned it very much, and on further investigation I found that he was using as a source the commercial lighting circuit, and he had not become familiar with the galvanometer, and inadvertently he tuned in for the third harmonic; in other words, he was balancing up the third harmonic and in his calculations he obtained a power factor which was one-third of what he should have obtained.

P. L. Hoover: I will reply first to Mr. Atkinson's statement that in balancing a bridge "it is necessary to secure a very accurate capacity balance before the power-factor balance can be obtained." It can be shown mathematically that this effect is inherent in the bridge and does not depend on the type of measuring instrument used. Furthermore, with the Wien and Schering bridges it can also be shown that the power factor, as determined by a minimum deflection of the detecting instrument, may be in error by 50 or 100 per cent if the capacity balance is out by about one per cent. This effect does not enter in the bridge used for this investigation. With this new bridge an accurate capacity balance can not be obtained if the power-factor balance is out very far. The two balances must be obtained simultaneously.

Furthermore, an amplifier is not necessary with this bridge although it helps considerably at the lower voltages if the sample is small. At higher voltages, above 25 kv., the amplifier is not used.

The question raised by Professors Kouwenhoven and Whitehead concerning the grounding of the condenser shield through a resistance is interesting in that it points out another advantage of this new bridge over the Wien and Schering bridges. Since, with the latter bridges, it is necessary to make the capacity balance to extraordinary precision in order to get a fair precision in the power-factor balance, it is essential to maintain the guard ring or shield at exactly the same potential as the low-voltage electrode of the condenser. Otherwise the effective capacity of the condenser will change due to the change in the potential distribution within the condenser. This effect is largely eliminated in this new bridge since the power-factor balance does not depend upon such a critical balance of the capacitances.

It should also be noted that the resistance in the shield circuit is not a constant, neither is it equal to the resistance in the other arms of the bridge. If C_1 and C_2 represent the capacitances of the low-voltage electrode and the shield respectively, and R_1 and R_2 the resistances in series with these capacitances, then, for the shield to be at the same potential as the low-voltage electrode the shield resistance must be $R_1 = R_2 (C_1 \; C_2)$. Consequently the resistance in the shield must be changed every time the bridge is changed. With the Wien and Schering bridges this effect is very important and accounts for Prof. Whitehead's observation that a small change in the shield resistance may change the power factor by 50 to 100 per cent.

Check measurements made since the writing of this paper have shown that the angle of our air condenser was due to insufficient shielding of the lead from the low-voltage electrode of our air condenser as Prof. Kouwenhoven has pointed out. In our particular case there was magnetic coupling as well as electrostatic. Shielding corrected the difficulty and our air condenser now has no measurable loss.

ILLUMINATION ITEMS

By Committee on Production and Application of Light

THE LIGHT-COLOR PLAYER*

If, by a person seated at an instrument, illumination could be as flexibly and delicately controlled as sound can be by one seated at a piano, is it not conceivable that we should have a new method of emotional expression which might ultimately become a rival to music, or at least a valuable and glorious accompaniment to it?

While the main problem involved in designing such an instrument has always been the flexible and continuous grading of the intensity of illumination from darkness to its highest pitch, and vice versa, of course the problem of color-play at once assumed its interactive importance. Color is so wonderful a phenomenon in the act of seeing that it could not be ignored in the attempt to express emotion through the sense of vision; such a source of highly pleasurable sensations must be taken advantage of. And yet the injection of color-play has tended, in the popular mind, to obscure the full appreciation of what light-play is.

Through long association with lighting effects on the stage, or by watching moving picture screens, one naturally thinks of color-play on screen or stage, as being something at which an audience would sit and look. It is true that colors may be most beautifully presented when thrown on a monochromatically reflecting screen—preferably a white silvered curtain, hanging in loose folds. And it may be that while color-play on such a curtain, or on other objects or surfaces of a stage, will constitute an important feature of this new art, yet, after all, this is but a fraction of its main object. To produce its maximum emotional effect, or, conversely, to express most fully the emotions of the performer, the illumination of the whole interior must be played upon. This is because of the very wide seeing angle of the eye—both horizontally and vertically—and because illumination, like the atmosphere, is all pervading, surrounding the whole person and the whole assemblage of persons. If the highest expression of this new art is to be conveyed a play on that all enveloping illumination must be secured.

This light play in the illumination of the interior should not be thought of as a mere grading up and down of intensity—with or without color changes. It is not confined to that, but may constitute an extension of the space to be illuminated. Starting, for instance, with a brilliantly lighted curtain and the auditorium in darkness, the glow may be made to grow in area, with the smoothness of a dawn, from a spot on the curtain to gradually reach the rear and covers the whole

*From a paper presented before a meeting of the Philadelphia Section of the Illuminating Engineering Society, Jan. 26, 1926, by Mary Hallock Greenewalt.

interior. In other words, a climax may be reached either by gradually increasing the intensity throughout or the area illuminated. And, of course, either of these processes may be reversed, or, to a certain extent, they may be combined.

This play on the whole interior illumination may be illustrated by phenomena of nature. Everyone is familiar with the change of mood which accompanies the passing of a heavy cloud across the face of the sun, or the gradual transformation of a brilliant morning into a cloudy day. Also, how ominous is an unusually heavy cloud, producing near-darkness at midday! Conversely, how may one's mood change when an overcast gloomy day clears at sunset and fills the world with glorious radiance and, be it observed, with glorious color. A day of doubt and skepticism closes with the conviction that "all's right with the world." Again, who has not been seated on terrace or lawn of a summer evening and become conscious of a soft radiance suffusing the landscape, slowly growing in clearness, until the full moon, having risen behind the foliage and at last surmounting the tree tops, spreads its glorious illumination through all space? The magic effect is not that of something viewed, but of being bathed in universal radiance. Depending on the arrangement of lamps, effects of similar type may be produced in any interior by one seated at the console of this light-color player. And color-play is not necessarily confined to screen or curtain on the stage, but may be suffused throughout the interior.

A play of light and color on a curtain or stage, watched by an audience seated in uniform darkness, or near-darkness, may be compared to a performance of music in the presence of a uniform buzzing or hissing sought throughout the auditorium. For its perfect enjoyment, music must be the only sound reaching the ear; it must be unconfused in the whole interior and dominate the consciousness of the listener. So it is with the play of light; it must be capable of filling the whole eye of the watcher and of dominating his emotions.

It probably goes without saying that this art of mobile light admits of projecting changing patterns or shapes (coloring them as desired) by providing mechanism for gradually changing the shapes of the beams thrown by the projecting lamps. The earliest experiments, many years ago, were concerned with this type of light and color-play, but it was soon realized that it is but one small phase of the main problem in developing this art of mobile light and color. However, it is an inclusive phase.

The console contains three rheostats, each about 30 30 in. high by 36 in. long, so designed and arranged that the illumination intensity given by the lamps connected to them can be changed by steps so small as to seem continuous. Mercury switches absolutely noiseless of operation are used, so arranged that the same body of mercury makes contact between a choice of various pairs of conducting leads. The console is relatively light in weight and is about 30 in. wide by 42 in. long. The seated player controls the play of light and color by using keys and pedals.

The auditorium accessory consists of an arrangement of switches in a separate compact box not over 20 in. long, connected to the console and to the wiring of the auditorium lighting system in such a manner that the illumination in large auditoriums, even those consuming a wattage as high as 250,000, may be varied up or down at will by minute steps, so as to seem continuous. The regular lighting system of an auditorium may be so connected and utilized, but, of course, if special effects are desired, or color effects, special lamps would need to be properly placed.

The lamp head is designed for getting different colors from exactly the same point and to save wattage. The lamp is mounted in a special reflector, and fitted with a color wheel equipped with variable timing control, and a color signalling attachment. For color-play on curtain or stage, the lamps would naturally be placed as the character of the distribution is helped. Separate lamps, each with its fixed color screen, may be used in place of the color wheel. Of course, for certain limited or temporary purposes, where it is desired to use the instrument for color-play as a stereopticon, the lamp head, or several of them, may be mounted directly on the console, thus providing a self-contained portable color-player.

A musical composition to secure permanence and permit of indefinite performance by others needs a written record. So with a light composition. A system of scoring has been designed for light compositions which anyone familiar with musical scores can easily master, and a basis of permanence for this new art is thus laid.

The development of an instrument to play with light and color, to be operated by one person, must have awaited the advent of the incandescent electric lamp; it could not have been done with the light from the candle, kerosene lamp or gas lamp. It has been helped by the development of high wattage, high candle power lamps, and of various technical devices, such as the mercury switch. It must have awaited facts developed by physiological research, including the seeing increments of the eye under varying intensities. A new means of emotional expression and of esthetic enjoyment is thus given to the world—who can predict the extent of its ultimate development? Perhaps a time will come when it will be a factor in heightening the enjoyment of music, deepening the devotion of religious worship, augmenting the effect of oratory, enhancing the brilliancy of dances, banquets and social functions, beautifying and refining whatever may be done on the stage, platform, or motion picture screen, and, when played on the silver curtain, becoming in itself a source of joy to the following generations.

Annual Convention at White Sulphur June 21-25

A wide variety of technical subjects, the choice of a charming location, and enjoyable recreational features mark the program for the Annual Convention of the A. I. E. E. which will be held at The Greenbrier, White Sulphur Springs, W. Va., June 21-25, 1926.

Technical Sessions

The technical papers cover a broad range of subjects and the reports of the Technical Committees will describe the important developments which have occurred in the various fields of electrical theory and application. The papers will include the subjects of the theory of synchronous machines, non-harmonic alternating currents, a-c. circuits, dielectric breakdown, rectifiers, magnetization, heat transfer in machines, auto-transformers, electrical measurement of mechanical vibrations, remotely controlled substations, high-speed circuit breakers, regenerative braking and windings for d-c. machines. The accompanying tentative program gives more detailed information on the technical features.

The Attractive Location

No finer place than the Greenbrier at White Sulphur Springs could have been selected for the convention. This magnificent, modern hotel is located in the Greenbrier Mountains 2000 feet above sea level in most attractive surroundings. Small cottages, close to the main hotel, are available for those who desire them. There is every opportunity for outdoor sports and recreation. Close to the hotel there are two 18-hole golf courses which are among the finest in the country and also a splendid nine-hole course. Excellent tennis courts will be available and both golf and tennis tournaments are planned.

A swimming pool, 40 by 103 ft. in size and fed from one of the large springs, is another attraction at this hotel.

A fine stable of thoroughbred horses is maintained there and those interested may enjoy horseback riding on well kept trails over the mountain ridges through very beautiful scenery. Also automobile driving is very enjoyable in this country and many people motor to the Greenbrier from New York, Philadelphia and Washington.

Special Addresses

An interesting feature of the meeting will be the addresses on three organizations which play an important part in the electrical industry, namely, the International Electrotechnical Commission, the American Engineering Council and the American Engineering Standards Committee. The speakers will be C. H. Sharp, President of the U. S. National Committee of the I. E. C., L. W. Wallace, Executive Secretary, A. E. C., and C. E. Skinner, Chairman A. E. S. C. Many members will be glad to hear these talks on the objects, organization and activities of these bodies.

Recreation

The recreational side of the convention is receiving special attention and every afternoon will be free for sports and pleasure. There will be a reception and dance on Tuesday evening of the convention week and dancing will be enjoyed on other evenings.

The ladies will be especially welcome and many plans are being made for their enjoyment.

Section Delegates' Conference

During the morning and afternoon of Monday, June 21, a conference of the delegates of Institute Sections will be held under the suspices of the Sections Committee, but all interested are welcome to attend.

Registration and Hotel Accommodations

It will be appreciated if those who plan to attend the convention will notify Institute headquarters, 33 W. 39th Street, New York, as soon as possible.

Hotel accommodations should be reserved by communicating directly with The Greenbrier, White Sulphur Springs, W. Va. A list of rates is given below.

Rates per Person at The Greenbrier

Cost of Meals is Included

Single room without bath	$9.00
Single cottage room with use of bath (average five rooms per cottage with two or three baths)	$10.00
Double room (twin beds) and single room with bath between	$10.00
Two double rooms (twin beds) with bath between	$10.00
Two single rooms with bath between	$11.00
Double room (twin beds) with bath	$11.00
Single room with private bath	$12.00

Reduced Railroad Rates

Special railroad rates have been granted for those who attend the convention. These rates are available under the "certificate plan" which requires that each member or guest request a certificate when purchasing his railroad ticket to White Sulphur Springs. If 250 certificates are deposited with the Transportation Committee at The Greenbrier, each certificate holder is entitled to half-fare on his return trip over the same route. There are certain restrictions as to some limited trains, date of travel, etc., on which information should be obtained from local ticket agents.

Every member and guest should get a certificate whether or not he will use it. This will insure that those who want to take advantage of the reduced fare will not be deprived of the opportunity.

The following table shows the schedules on trains arriving in the morning in White Sulphur Springs from several cities. While this schedule will probably be in effect until after the convention, members should consult their local ticket agents relative to trains. It is advised that parlor-car and sleeping-car accommodations be reserved at the earliest possible date.

The general committee in charge of arrangements for the convention is as follows: Farley Osgood, Chairman, W. R. Collier, W. S. Lee, E. B. Meyer, W. E. Mitchell, A. M. Schoen and H. B. Smith.

SCHEDULE OF TRAINS ARRIVING AT WHITE SULPHUR SPRINGS IN THE MORNING

From the East

Lv. New York, Penn. Sta.	Penn. R. R.	5:45 p. m. (E.S.T.)
Lv. West Philadelphia	Penn. R. R.	7:53 p. m. (E.S.T.)
Lv. Wilmington	Penn. R. R.	8:34 p. m. (E.S.T.)
Lv. Baltimore	Penn. R. R.	10:00 p. m. (E.S.T.)
Lv. Pittsburgh	B. & O. Ry.	12:55 p. m. (E.S.T.)
Lv. Washington	C. & O. Ry.	11:20 p. m. (E.S.T.)
Ar. White Sulphur Springs	C. & O. Ry.	7:25 a. m. (E.S.T.)

This train carries through Pullman sleepers from New York.

From the West

Lv. Chicago	Big Four Ry.	1:00 p. m. (C.S.T.)
Lv. Indianapolis	Big Four Ry.	6:15 p. m. (C.S.T.)
Lv. St Louis	Big Four Ry.	12:00 Noon (C.S.T.)
Lv. Detroit	Mich. Cent. Ry.	12:20 Noon (E.S.T.)
Lv. Toledo	Big Four Ry.	2:00 .p m. (E.S.T.)
Lv. Louisville	C. & O. Ry.	6:00 p. m. (C.S.T.)
Lv. Cincinnati	C. & O. Ry.	9:10 p. m. (C.S.T.)
Ar. White Sulphur Springs	C. & O. Ry.	8:40 a. m. (E.S.T.)

This train carries through Pullman sleepers from Chicago, St. Louis, Cincinnati and Louisville to White Sulphur Springs.

E.S.T = Eastern Standard time C.S.T = Central Standard time.

TENTATIVE TECHNICAL PROGRAM

Tuesday Morning, June 22

President's Address, Dr. M. I. Pupin

Presentation of A. I. E. E. Prizes for Papers

Developments in Electrical Engineering as described in the reports of the Technical Committees and of the Standards Committee as indicated below.

Research, J. B. Whitehead, Chairman.
Electrophysics, J. H. Morecroft, Chairman.
Education, Harold Pender, Chairman.
Standards, H. S. Osborn, Chairman.
Instruments and Measurements, A. E. Knowlton, Chairman.
Communication, H. P. Charlesworth, Chairman.
Production and Application of Light, P. S. Millar, Chairman.
Electrical Machinery, H. M. Hobart, Chairman.

Wednesday Morning, June 23

Session A

Synchronous Machines (Extension and Interpretation of Blondel's Treatment), R. E. Doherty and C. A. Nickle, both of General Electric Co.

Non-Harmonic Alternating Currents, Frederick Bedell, Cornell University.

Graphical Solution of A-C. Circuits, F. W. Lee, Johns Hopkins University.

Session B

Remote Controlled Substations, W. C. Blackwood, N. Y. & Queens Elec. Lt. & Pr. Co.

The High-Speed Circuit Breaker in Railway Feeder Networks, J. W. McNairy, General Electric Co.

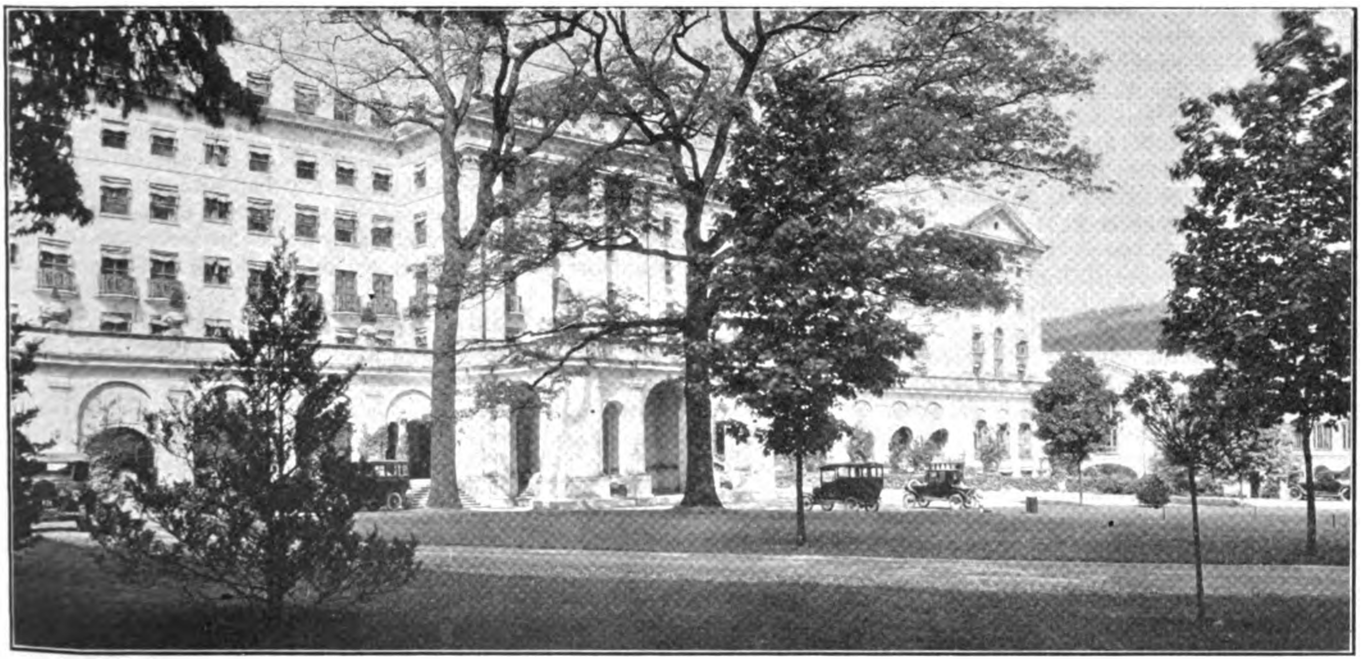
Regenerative Braking for D-C. Locomotives, Alfred Bredenberg, Jr., General Electric Co.

Multiplex Windings for D-C. Machines, C. C. Nelson, Massachusetts Inst. of Technology.

Thursday Morning, June 24

Developments in Electrical Engineering as described in the reports of the Technical Committees indicated below.

Power Generation, V. E. Alden, Chairman.
Power Transmission and Distribution, P. H. Thomas, Chairman.
Protective Devices, E. C. Stone, Chairman.
General Power Applications, A. M. MacCutcheon, Chairman.
Applications to Iron and Steel Production, F. B. Crosby, Chairman.
Applications to Mining Work, F. L. Stone, Chairman.
Applications to Marine Work, L. C. Brooks, Chairman.
Transportation, C. T. Hutchinson, Chairman.
Electrochemistry and Electrometallurgy, G. W. Vinal, Chairman.



A. I. E. E. Convention Headquarters—Greenbrier Hotel, White Sulphur Springs

FRIDAY MORNING, JUNE 25
SESSION A

The Mechanism of Breakdown of Dielectrics, P. L. Hoover, Harvard University.

Mercury-Arc Rectifiers, D. C. Prince, General Electric Co.

Electrical Recording of Vibrations, A. V. Mershon, General Electric Co.

SESSION B

Law of Magnetization, S. L. Gokhale, General Electric Co.

Surface Heat Transfer in Electric Machines with Forced Air Flow, O. E. Luke, Westinghouse Elec. & Mfg. Co.

General Theory of the Auto-Transformer, W. L. Upson, Washington University.

The Niagara Falls Regional Meeting

As we go to press with this issue of the JOURNAL, the Regional Meeting of the A. I. E. E. at Niagara Falls, N. Y., is convening for its first session. The number of early arrivals registered indicates an unusually good attendance, and the diversified program and excellent weather conditions which prevail presage a most interesting and enjoyable time for both the indoor and outdoor features of the meeting. The program was published in full in the May JOURNAL and preliminary copies have been mailed to all the membership in the eastern part of the United States. A complete account of this meeting will appear in the July JOURNAL.

Regional Meeting Held at Madison

The first regional meeting of the Great Lakes District of the Institute was held in Madison, Wis., May 6 and 7, with headquarters in the Hotel Loraine. It was most enjoyable and instructive to the one hundred eighty who attended. There were three well attended technical sessions, a regional dinner, and a number of interesting trips.

At the first session on Thursday, May 6, two papers were presented, namely, *Rural Electrification*, by G. C. Neff, and *Important Features of a Successful Plan for Rural Electrification*, by G. G. Post. Quite a number discussed these papers. Included were E. A. Stuart, A. H. Ford, E. H. Lehman, K. A. Pauly, Eugene Holcomb, C. B. Hayden and F. W. Duffee.

Three papers on high-voltage cable were presented Friday morning. These were as follows: *The Quality Rating of High-Tension Cable with Impregnated Paper Insulation*, by D. W. Roper and Herman Halperin; *Tests of Paper-Insulated, High-Tension Cable*, by F. M. Farmer; and *The Effect of Internal Vacua in High-Voltage Cables*, by W. A. Del Mar. These papers were received with great interest and extended discussion followed. Those taking part were: R. W. Atkinson, W. S. Clark, E. S. Lee, D. M. Simons, R. J. Wiseman, H. G. Burd, S. J. Rosch, Percy Dunsheath, E. C. Willman, F. A. Brownell, and E. M. Tingley.

Following these papers F. G. Boyce presented a paper on *Some Interconnected-System Operating Problems.* This was discussed by D. W. Roper, H. J. Burton, Carl Lee, and R. L. Dodd.

A session on *Cooperation between the Colleges and the Industries in Research* occupied Friday afternoon. Papers on this topic were read by the following: W. E. Wickenden (read by J. T. Rood), A. A. Potter (read by C. F. Harding), B. F. Bailey whose paper was entitled *Can the University Aid Industry?*, and Edward Bennett whose paper was entitled *Seminars for Practising Engineers.* Those contributing discussions were E. B. Paine, John Mills, S. H. Mortensen, J. S. Coldwell, F. E. Tourneur, and C. F. Harding.

L. J. Peters then presented a paper on *Behavior of Radio Receiving Systems to Signal and to Interference* which was discussed by Prof. Edward Bennett.

An enjoyable feature of the meeting was the regional dinner held on Thursday evening. A very inspiring address was made by Dr. Glenn Frank, President of the University of Wisconsin. Dr. Frank drew attention to the present sociological and economic problems of this country and suggested as possible remedies two courses of action. The first he called a "new scientific renaissance" which could be accomplished by making the knowledge of researchers in all lines of science available for general understanding and practical utilization. The second remedy he called a "new industrial revolution." The main lines of action in such a revolution would be four, namely, (1) to decentralize industry, (2) to regularize production and distribution, eliminating excessive seasonal activities, (3) to reduce unemployment, and (4) to allay the insecurity of the labor class. In elaborating on these propositions Dr. Frank suggested as one means of accomplishing them, the small factory making standardized parts and situated in farm territory where laborers might alternate between farm work and factory work.

Meetings of the Branch Counselors of the District were held on Thursday and Friday at which were present the counselors of ten Branches and several other professors who were interested.

Many of the visitors took the trips which were arranged in and around Madison and a number also found time to play golf.

Student Convention Held at M. I. T.

A convention of enrolled students of the Northeastern District of the A. I. E. E. was held at Massachusetts Institute of Technology, Cambridge, Mass., on May 7. The meeting, which was arranged by a student committee assisted by the Boston Section, had an attendance of one hundred sixty. There were three technical papers presented and a number of inspection trips were made. A banquet was also given.

At the technical session in the morning, at which S. A. Tucker, Chairman of the Yale Branch, presided, the following papers were presented: *D-C. Transmission Considerations*, by S. W. Marshall, M. I. T. graduate; *A Phase of Distribution Engineering*, by O. W. Briden, Brown 1926; and *Electrical Characteristics of Richmond Station of the Philadelphia Electric Company*, by Constantine Barry, M. I. T. 1927.

At the banquet in the evening, Prof. H. B. Smith, Vice-President in the Northeastern District, was toastmaster. Dr. S. W. Stratton, President of Massachusetts Institute of Technology, welcomed those present in a short talk, after which three addresses were made. Dr. M. I. Pupin, President of the A. I. E. E., chose as his subject *Science and Engineering.* He was followed by Prof. C. F. Scott, Yale University, who spoke on *How Student Branches Came into Being*, and R. E. Doherty, Consulting Engineer, General Electric Company, who spoke on *Employment with a Large Manufacturing Company.*

In the afternoon many took the trips which were made to the following places: Edgar Station of the Edison Electric Illuminating Company; the plant of the Simplex Wire and Cable Company; a machine-switching exchange of the New England Telephone Company; and the M. I. T. Laboratories.

A meeting and luncheon of the Branch Counselors of the District was held at which every Counselor was present besides a number of others interested in Branch and Section activities.

Establishing of Louisville Section

A meeting was held on May 13 in Louisville, Kentucky to consider the advantages of establishing a local Section of the Institute in that city. Some sixteen A. I. E. E. members were present and listened to an interesting talk on the value of local Sections given by W. E. Mitchell of the Alabama Power Company, Vice-President of the A. I. E. E. from the Southern District. It was decided that the establishing of a local Section in Louisville would be a distinct advantage to every one concerned and a committee was appointed to complete the formalities and present a report at a meeting to be held in September. Those named on the committee were, E. D. Wood, Operating Electrical Engineer, Louisville Gas & Electric Co. and D. C. Jackson, Jr., Professor of Mechanical and Electrical Engineering at the University of Louisville.

Cummings C. Chesney

PRESIDENT-ELECT OF THE A. I. E. E.

Cummings C. Chesney, Manager and Chief Engineer, General Electric Company, Pittsfield, Mass., has been elected President of the American Institute of Electrical Engineers for the year beginning August 1, 1926, as announced in the report of the Committee of Tellers published elsewhere in this issue.

President-elect Chesney was born in Selingsgrove, Pa., October 28, 1863. He was graduated from Pennsylvania State College in 1885, and for three years taught mathematics and chemistry. In 1888 he joined Mr. William Stanley's laboratory force at Great Barrington, Mass., and the following year entered the services of the United States Electric Lighting Company in Newark, N. J., a subsidiary of the Westinghouse Electric and Manufacturing Company. In 1890 he moved to Pittsfield, Mass., where he was one of the original incorporations of the Stanley Electric Manufacturing Company, started with a capital of $25,000. The company was organized to develop the alternating-current inventions of William Stanley, John Kelley and C. C. Chesney. The work was primarily of a pioneer character with little precedent to guide it.

C. C. Chesney

This company developed the well-known S. K. C. system (Stanley, Kelly, Chesney). The first polyphase transmission plant equipped with the S. K. C. system to be put into successful operation and the first in America was installed in 1893 and is supplying power and light today for use in the towns of Housatonic and Great Barrington, Massachusetts. In 1895 a 12,000-volt plant was installed for service from Lowell to Grand Rapids, Michigan. The operating success of these alternators was due to special design in which the high-tension currents were generated in the stator element by the revolving rotor, these being the first alternators to produce a true sine wave. As early as 1896 alternating-current generators of 6000 volts with control equipment were put into successful operation on the transmission line of the Montmorency Electric Power Company, Quebec. In 1898 generators up to 12,000 volts were placed in service. During the early period two-phase alternating-current induction motors were developed, electrostatic condensers at 500 volts and electric transformers of 100-light capacity. In developing the transformer all spaces in the coils were filled with Gilsenite to provide better heat dissipation and insulation. This occurred as early as 1892, as did the development of cloth treated with oxidized linseed oil. The most effective general insulation in use today was developed by the Stanley Company, in 1891-1892, superseding the old insulating methods using shellac and P. & B. paint. In 1893 belt-driven alternators were put into successful operation and in 1899 alternators of this design direct-connected to steam engines went into successful operation in the power house of the Staten Island Electric Company. These were the first alternators to be operated in parallel and in regular commercial service. Switchboard instruments, high-tension arc breaking devices, frequency indicators, indicating wattmeters, lightning protection for high and low-tension currents, condensers, etc., were among other apparatus manufactured by the Stanley Company. The company built the first revolving field types of alternators used in America. These were extensively used in hydraulic stations, notably the Bay Counties and Standard companies' lines in California, at that time the longest high-voltage lines in the world, using 40,000 to 60,000 volts.

Mr. Chesney was vice-president and chief engineer of the Stanley Company from 1904 to 1906. On the latter date he took up the duties of chief engineer and manager of the Pittsfield works of the General Electric Company, which company had acquired the Stanley Manufacturing Company. Under Mr. Chesney's supervision the Pittsfield works in recent years have made particular progress in the development of apparatus for commercial service up to 220,000 volts, and lately have completed successful tests of 1,000,000 volts for transmission purposes.

Mr. Chesney is a Fellow of the Institute, and has taken an active interest in its affairs. He served as manager from 1905 to 1908 and as vice-president from 1908 to 1910. He is also a member of the Society of Arts, London, of the American Society for the Advancement of Science and of the Engineers Club of New York. During the year 1920 he was president of the Engineering Society of Western Massachusetts. He has always had a strong civic interest, taking an active part in the life of his community. He is chairman of the industrial committee of the crippled

children's home in Pittsfield, one of the best equipped industrial rehabilitation schools for children in New England; and is director of the Agricultural Bank and president of the Morris Plan Bank of Pittsfield.

The Edison Medal was awarded to Mr. Chesney in 1921, "for early developments in alternating-current transmission."

A. I. E. E. Directors' Meeting

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Friday, May 21, 1926.

There were present: President M. I. Pupin, New York; Vice-Presidents Harold B. Smith, Worcester, Mass.; Arthur G. Pierce, Cleveland, Ohio; Managers H. M. Hobart, Schenectady, N. Y.; G. L. Knight, Brooklyn, N. Y.; National Secretary F. L. Hutchinson, New York.

A minute was adopted in memory of the late Carl Hering, Past President of the Institute.

Reports were presented of meetings of the Board of Examiners held April 26 and May 17, 1926, and the actions taken at those meetings were approved. Upon the recommendation of the Board of Examiners, the following actions were taken upon pending applications: 93 Students were ordered enrolled; 164 applicants were elected to the grade of Associate; 18 applicants were elected to the grade of Member; 1 applicant was elected to the grade of Fellow; 3 applicants were transferred to the grade of Fellow; 18 applicants were transferred to the grade of Member.

The Board ratified the approval by the Finance Committee, for payment, of monthly bills amounting to $21,343.99.

The National Secretary reported 1330 members delinquent in the payment of dues for the fiscal year ending April 30, 1926; and the Board directed that the usual efforts be continued to collect these dues, through the Secretary's office and by bringing the list to the attention of the Section officers concerned.

The annual report of the Board of Directors for the fiscal year ending April 30, 1926, as prepared in the National Secretary's office was presented and accepted for presentation at the annual business meeting of the Institute to be held during the evening of the same day. The annual report of the National Treasurer was presented, accepted, and ordered filed.

The annual reports of various standing committees (exclusive of the technical committees, whose reports will be presented at the Annual Convention in June), abstracts of which were incorporated in the Board of Directors' report, were received and ordered filed for reference by the committees of the next administration.

The following new by-law was adopted, in order to incorporate in the Institute by-laws the action taken by the Board of Directors on April 9, 1926, in adopting the policy of providing for the affiliation with the Institute of engineering student organizations in colleges in which it is not feasible to establish Student Branches of the Institute because of the limited number of students:

"SEC. 59A. An established student engineering society in a university or technical school of recognized standing may, upon application of its officers and a member of the Institute connected with the school, and the approval of the Board of Directors, become associated with the Institute. Members of such associated student engineering society may have the same privileges as enrolled Students of the Institute and will be governed by the same requirements."

Upon the recommendation of the Committee on Student Branches, the Board approved for printing and distribution in pamphlet form, "Suggested By-laws for Student Branches."

The Standards Committee submitted for the Board's approval, a revision of Section 7 of the A. I. E. E. Standards (Alternators, Synchronous Motors and Synchronous Machines in General), and the Board voted to approve the recommended revision.

An invitation to nominate a candidate for the 1926 Kelvin Medal was accepted and referred to the President with power. President Pupin stated that he would confer with the presidents of the other Founder Societies before acting in the matter.

In accordance with Section 37 of the constitution, the Board considered the appointment of a National Secretary for the administrative year beginning August 1, 1926, and National Secretary F. L. Hutchinson was reappointed.

Other matters of importance were discussed, reference to which may be found in this and future issues of the JOURNAL.

Board of Directors' Report for the Year Ending April 30, 1926

The annual report of the Board of Directors of the American Institute of Electrical Engineers was presented at the annual business meeting of the Institute held in New York Friday evening, May 21.

This report consists of a brief summary of the principal activities of the Institute during the year, including abstracts of various reports submitted by officers and committees, covering their respective branches of work. The more important matters referred to in the report have been, or will be, covered in much more detailed form in the JOURNAL, and therefore the report will not be published in full herein; but any member of the Institute may obtain a pamphlet copy upon application to the National Secretary.

The growth in Institute membership during the year is indicated in the following tabulation:

	Honorary	Fellow	Member	Associate	Total
Membership on April 30, 1925	4	597	2,436	14,282	17,319
Additions:					
Transferred		33	178		
New Members Qualified		5	97	1,976	
Reinstated			8	45	
Total	4	635	2,719	16,303	
Deductions:					
Died		7	16	71	
Resigned		2	36	333	
Transferred			18	193	
Dropped		1	26	800	
Membership, April 30, 1926	4	625	2,623	14,906	18,158
Net increase in Membership during the year					839

The activity of the Sections and Branches during the year and the growth in the number of these organizations, also in the number of meetings held by them and in the aggregate attendance, are shown in the following statement:

	For Fiscal Year Ending			
	May 1 1919	May 1 1921	May 1 1923	May 1 1926
SECTION				
Number of Sections	34	42	46	51
Number of Section meetings held	217	303	344	405
Total Attendance	25,837	37,823	46,672	58,959
BRANCHES				
Number of Branches	61	65	68	86
Number of Branch meetings held	156	443	503	714
Attendance	6,441	21,629	26,893	35,270

The Finance Committee's report, together with the general balance sheet and detailed financial statements of the public accountants who audited the Institute's books, is included in the report.

Report of Committee of Tellers on Election of Officers

To the President,
American Institute of Electrical Engineers

DEAR SIR:

This committee has carefully canvassed the ballots cast for officers for the year 1926-1927. The result is as follows:

Total number of ballot envelopes received		4811
Rejected on account of bearing no identifying name on outer envelope, according to Art. VI, Sec. 34 of the Constitution	43	
Rejected on account of voter being in arrears for dues for year ending May 1, 1926, as provided in the Constitution and By-Laws	99	
Rejected on account of ballot not being enclosed in inner envelope, or being improperly marked, or on account of inner envelope or ballot bearing an identifying name, according to Art. VI, Sec. 34, of the Constitution	111	
Rejected on account of having reached the Secretary's office after May 1, according to Art. VI, Sec. 34, of the Constitution	14	267
Leaving as valid ballots		4544

These valid ballots were counted, and the result is shown as follows:

For President	
C. C. Chesney	4399
Blank	145
For Vice-Presidents	
District	
No. 1 *North Eastern*	
H. M. Hobart	4397
Blank	147
No. 3 *New York*	
G. L. Knight	4385
Blank	159
No. 5 *Great Lakes*	
B. G. Jamieson	4402
Blank	142
No. 7 *South West*	
A. E. Bettis	4362
Blank	182
No. 9 *North West*	
H. H. Schoolfield	4371
Blank	173
For Managers	
F. J. Chesterman	4441
Blank	103
H. C. Don Carlos	4433
Blank	111
I. E. Moultrop	4439
Blank	105
For Treasurer	
George A. Hamilton	4407
Blank	137

Respectfully submitted,

SERGIUS P. GRACE, *Chairman*
E. S. HOLCOMBE
W. E. COOVER
E. F. THRALL
E. F. WATSON
J. T. WELLS
Committee of Tellers.

Date May 10, 1926.

Annual Meeting of A. S. T. M.

The Twenty-Ninth Annual Meeting of the American Society for Testing Materials will be held at Chalfonte-Haddon Hall, Atlantic City, N. J., June 21-25 inclusive. The program will be diversified including the following sessions: Tuesday morning Committee Meetings; afternoon, First Session, Wrought Iron, Cast Iron and Magnetic Testing. Wednesday, June 23, (a. m.) Third Session, Steel; Fourth Session, Brick, Tile, Refractories and Fire Tests; Fifth Session, (p. m.), Edgar Marburg Lecture. Thursday, June 24, (a. m.), Sixth Session, Corrosion and Fatigue of Metals; Seventh Session, Road Materials, Waterproofing, Petroleum Products and Thermometers. Evening Sessions, Non-Ferrous Metals and Metallography; Textiles, Rubber, Coal, Timber, Insulating Materials and Slate. Tenth Session, Symposium on Resin. Friday, June 25th, (a. m.), Eleventh Session, Preservative Coatings and Naval Stores; Twelfth Session, Cement, Lime, Gypsum and Nomenclature.

Special, reduced rates have been prearranged for those who wish to attend if 250 certificates are filed, and as he registers, each member will receive a complete set of reports and papers prepared for this meeting. Golf and tennis tournaments, an informal dance and smoker will supply entertainment of a more recreative nature.

1926 Convention of the Illuminating Engineering Society

The Twentieth Annual Convention of the Illuminating Engineering Society will be held at Spring Lake, N. J., from September 7-10, inclusive, with headquarters at the Essex and Sussex Hotel. The Essex and Sussex is ideally located directly on the ocean front, a short trip from New York and Philadelphia. It is beautifully appointed and enjoys a most enviable reputation for its service and cuisine.

A well-rounded papers program is being prepared with special features showing the developments in specific fields which have taken place during the twenty years of existence of the Society. Special and unique features are also being planned for the entertainment program and it is confidently expected that the 1926 Convention will prove to be a most successful one.

Annual Meeting and New York Section Meeting, May 21, 1926

The annual business meeting of the Institute was held at the Engineering Societies Building, New York, on Friday evening, May 21, 1926. President Pupin presided, and called upon National Secretary Hutchinson, who presented in abstract the annual report of the Board of Directors, printed copies of which had been distributed to members in attendance. (This report is referred to elsewhere in this issue).

The report of the Committee of Tellers on the election of officers of the Institute was then presented by Mr. Hutchinson, and, in accordance therewith, President Pupin declared the election of the following officers, whose terms will begin on August 1, 1926:

PRESIDENT:	Cummings C. Chesney, Pittsfield, Mass.
VICE-PRESIDENTS:	
District No. 1	H. M. Hobart, Schenectady, N. Y.
District No. 3	George L. Knight, Brooklyn, N. Y.
District No. 5	B. G. Jamieson, Chicago, Ill.
District No. 7	A. E. Bettis, Kansas City, Mo.
District No. 9	H. H. Schoolfield, Portland, Ore.
MANAGERS:	F. J. Chesterman, Pittsburgh, Pa.
	H. C. Don Carlos, Toronto, Ont.
	I. E. Moultrop, Boston, Mass.

NATIONAL TREASURER: George A. Hamilton, Elizabeth, N. J.

These officers, together with the following hold-over officers, will constitute the Board of Directors for the next administrative year, beginning August 1: M. I. Pupin, New York; Farley Osgood, New York; P. M. Downing, San Francisco, Calif.; Herbert S. Sands, Denver, Colo.; W. E. Mitchell, Birmingham, Ala.; Arthur G. Pierce, Cleveland, Ohio; W. P. Dobson, Toronto, Ont.; W. M. McConahey, Sharon, Pa.; W. K. Vanderpoel, New York; H. P. Charlesworth, New York; John B. Whitehead, Baltimore, Md.; J. M. Bryant, Austin, Tex.; E. B. Merriam,

Schenectady, N. Y.; M. M. Fowler, Chicago, Ill.; H. A. Kidder, New York; E. C. Stone, Pittsburgh, Pa.

Dr. Pupin then called upon Mr. H. A. Kidder to preside during the remainder of the meeting which was under the auspices of the New York Section.

Chairman Kidder, after a few preliminary remarks on the value of modern methods of obtaining data on circuit breaker performance as compared with the early days when the certainty of performance of a breaker was an almost unknown quantity, introduced the speaker of the evening, W. R. Woodward, General Engineer, Westinghouse Elec. & Mfg. Co., Pittsburgh, Pa. In the presentation of his paper, "A High-Power Laboratory for Testing Oil Circuit Breakers and Other Apparatus," Mr. Woodward outlined the advantages and disadvantages of factory testing as compared to field tests, described the ever increasing demand for larger and larger test sets, and the effort which has been made to make the laboratory complete, flexible, and safe. The paper was profusely illustrated with lantern slides. Discussion of the paper was given by R. M. Spurck, G. E. Co., and E. K. Read of the Westinghouse Co.

The Montefiore Triennial Prize

April 30, 1927 has been set as the latest date upon which papers may be submitted to the jury of award for the George Montefiore Foundation Medal.

This prize is awarded every three years upon the basis of international competition for the best original work in scientific progress and progress in technical application of electricity in any of its branches. Popular works and simple compilations are precluded. Papers submitted are subject to the following general stipulations:

Only such papers as have been prepared during the three years preceding the meeting of the acting jury will be acceptable; all must be either printed or typewritten, in both French and English, and twelve copies sent free of postage to M. le secretaire-archiviste de la Foundation George Montefiore, rue Saint-Gilles, 31 Liege, Belgium, by whom they will be acknowledged to the author. A majority vote of four-fifths by the board of award allows of one-third of the amount available being bestowed for the presentation of a valuable discovery in the scientific field or the statement of a new idea which may lead to important development in electrical progression. Should the prize for any year not be awarded or any portion of it remain undistributed this amount will be added to the award for the next triennial period. Any paper upon which the jury decides will be published in the Bulletin de l'Association des Ingenieurs électriciens of l'Institut électro-technique Montefiore, 25 reprints to be sent to the author free of charge but no further profit to be derived by him from its reprinting. The award carries with it a gratuity of 20,500 francs (about $600) to be distributed at the discrimination of the jury of award, which is comprised of ten electrical engineers, all holding diplomas of the Institute Electrotechnique Montefiore, five Belgians and five others, presided over by the director of the Institute Electro-Technique Montefiore, who automatically becomes one of the Belgian delegates.

At the head of all papers submitted, or in some other conspicuous place should be plainly written: "Travail soumis au concours de la Foundation George Montefiore, session de 1923-1926" (Paper submitted for the competition of the George Montefiore Foundation).

American Engineering Standards Committee

WELCOME SUGGESTIONS ON SYMBOLS AND ABBREVIATIONS

Under the auspices of the American Engineering Standards Committee, an undertaking which will lead eventually to the standardization of scientific and engineering symbols and abbreviations has now been fairly launched. The sectional committee, which in its representation includes thirty-one trade, technical and scientific bodies, held its organization meeting January 21, 1926, societies taking the leading part in the work as sponsors being, the American Association for the Advancement of Science, the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Society of Mechanical Engineers and the Society for the Promotion of Engineering Education. The secretary of the sectional committee, (Preston S. Millar, Electrical Testing Laboratories, 80th Street and East End Avenue, New York City) will be very glad to receive in cooperation any suggestions which interested organizations may care to make with regard to symbols and abbreviations to be adopted in the various fields of engineering and industry. Completion of the entire work will require the participation of many interests, it is the committee's present plan to concentrate upon the fields in which there is the greatest need of unification of standards, taking up further work as opportunity affords.

Carnegie Institute Summer Course

Excepting a few guest instructors and special lecturers, none but members of the regular college teaching staff has been appointed to the faculty for the summer courses this year at the Carnegie Institute of Technology, according to an announcement from the Pittsburgh institution. The guest members of the faculty, it is further announced, will be on duty at various periods during the six weeks' courses for teachers from June 28 to August 6 in the College of Fine Arts. For the eight weeks' courses from June 4 to August 6 for undergraduates in the industrial and engineering courses, only members of the regular college faculty have been engaged.

As a result of the increasing interest shown in the type of technical instruction featured at this institution. Carnegie officials report plans to receive another large enrolment of summer students for this year.

ENGINEERING FOUNDATION

EDWARD DEAN ADAMS GIVES GENEROUSLY TO RESEARCH

A gift of $100,000 has been made to the Engineering Foundation and the Engineering Societies Library by Edward Dean Adams, as announced by W. L. Saunders President of the United Engineering Society and Chairman of its endowment committee at a meeting of the Foundation the evening of May 19th when a dinner was held at the Union League, with Mr. Adams as guest of honor.

This generous gift of Mr. Adams' brings research endowment fund up to a total of $650,000, with Mr. Ambrose Swasey's initial endowment of $500,000 and the $50,000 received under the will of the late Henry R. Towne.

The sum of $12,000 was contributed toward the support and promulgation of a fundamental research in blast furnace slags, now in progress at the University of Wisconsin under the direction of Richard S. McCaffery, member of the Institute of Mining Engineers and Professor of Metallurgy at the University. The investigation is being conducted with the understanding that information established by the work done will be contributed to the research data of the Engineering Foundation before the 20th of each January, covering progress of the preceding calendar year; any unused portion of the funds appropriated to revert to the Foundation.

The Foundation also voted $5000 a year for two years, to promote electrical insulation research on the specific subject of dielectric absorption, through investigation to be conducted at the Johns Hopkins University under the direction of John B. Whitehead, Fellow of the American Institute of Electrical Engineers and Professor of Electrical Engineering at Johns

Hopkins University. Results on these investigations are to be returned to the Foundation before January 20th of each year covering the previous calendar year with full accounting of the funds expended and return of any residue which may exist.

The personnel of the Endowment Committee is as follows:

Ex officiis:

W. L. Saunders, President, United Engineering Society, *Chairman.*

L. B. Stillwell, Chairman, Engineering Foundation.

Sydney H. Ball, Chairman, Library Board.

Nominees of American Society of Civil Engineers:

Charles F. Loweth, Chicago; Chief Engineer, Chicago, Milwaukee & St. Paul Railway.

H. deB. Parsons, New York; Consulting Engineer.

Ralph J. Reed, Los Angeles; Chief Engr., Union Oil Company.

Nominees of American Inst. of Mining and Metallurgical Engineers:

D. W. Brunton, Denver; Chairman, Board of Consulting Engineers, Moffatt Tunnel.

J. V. N. Dorr, President, The Dorr Company (metallurgical, chemical and sanitary process equipment). New York.

Thomas Robins, New York; President, Robins Conveying Belt Co., member, Naval Consulting Board.

Nominees of American Society of Mechanical Engineers:

J. W. Lieb, New York; Vice-President & General Manager, The New York Edison Company.

Wynne Meredith, San Francisco; member of firm, Sanderson & Porter.

E. A. Simmons, New York; President, Simmons-Boardman Publishing Company.

Nominees of American Institute of Electrical Engineers:

Calvert Townley, New York; Assistant to President, Westinghouse Electric & Manufacturing Company.

H. A. Lardner, Vice-President, J. G. White Engineering Corporation, New York.

E. Wilbur Rice, Jr., Schenectady; Honorary Chairman, General Electric Company.

Members-at-large:

Charles F. Rand, New York; Past-President, American Inst. of Mining and Metallurgical Engineers.

James H. Perkins, New York; President, The Farmers' Loan and Trust Company, financial adviser and custodian of securities for United Engineering Society.

H. Hobart Porter, New York, of Sanderson & Porter, and President, American Water Works & Electric Company.

Robinson Fellowship—Ohio State University

At a recent meeting of the Robinson Fellowship Committee it was voted to recommend Mr. Herbert L. Rawlins of Fredericktown, Ohio, Senior in Electrical Engineering, for the award of the Stillman W. Robinson Fellowship for the year 1926-27.

This fellowship has a value of $750 and provides that the successful applicant shall devote his entire time to graduate study and research, leading to the degree of Master of Electrical Engineering.

This fellowship was endowed by Stillman W. Robinson, formerly Professor of Mechanical Engineering and a famous inventor of shoe and other automatic machinery. Professor Robinson also gave the University the large experimental boiler in the Mechanical Engineering Department.

Dr. E. J. Berg Gives Steinmetz Lecture Before Schenectady Section

The second Steinmetz Lecture, entitled *The Solution of Transient Phenomena by Elementary Mathematics* was delivered by Dr. Ernst J. Berg, Professor of Electrical Engineering, Union University, at the meeting of the Schenectady Section on April 23. The Steinmetz Lectures are a series of annual addresses which was instituted last year by the Schenectady Section in honor of the late Dr. C. P. Steinmetz. The first address was given by Dr. M. I. Pupin in 1925. For the second lecture Dr. Berg selected a subject in which Dr. Steinmetz was deeply interested throughout his lifetime. The lecture was much appreciated by the 450 who were present. Copies of the address may be obtained from Institute headquarters, New York.

National Capital Park and Planning Commission

Since the development of plans for this Commission, engineers generally have been interested because of a proposal to make prominent engineers from the District of Columbia and elsewhere, members. Under the provision of the Act at least one man would be appointed from the District of Columbia and as announced on May 19th at the White House engineers are pleased to find a prominent member of their profession, F. A. Delano, on the list of appointees. Other men prominent in the engineering architectural development of city planning appointed to the and Commission by the President, were:

M. B. Medary, Philadelphia, Pa., President of the American Institute of Architects,

F. L. Ohmstead, of Boston, Mass.,

J. C. Nichols, of Kansas City, Mo.

Bureau of Standards Visiting Committee Meets

The Visiting Committee of the Bureau of Standards met with Director Burgess at the Bureau on April 29th. This body is composed of five scientists appointed by the Secretary of Commerce and entrusted with the work of going over the policy of the Bureau from time to time to look into the status of scientific experimentations and outline new phases of investigation.

It is understood that the Committee, during its recent meeting, went over the requirements of the Bureau of Standards and worked with the Director in developing some plans for the future. The nature of the Committee's report has not been disclosed. It was stated by Dr. George K. Burgess, Director of the Bureau, that the complete report will be submitted at a later date. The members of the Committee are: Wilder D. Bancroft, of Cornell University; Gano Dunn, New York; William F. Durand, New York; Samuel W. Stratton, Massachusetts Institute of Technology, and Ambrose Swasey, of Cleveland, Ohio. Prior to their meeting at the Bureau, the committee paid a complimentary call on Secretary Hoover.

Three members of the committee are also members of the American Institute of Electrical Engineers.

Stamp Memorial to John Ericsson

Postmaster General New has authorized a special five cent postage as a memorial to John Ericsson, engineer, builder of the *Monitor*, according to an announcement at the Post Office Department under date of May 5th. It is understood that an issue of 15,000,000 of these stamps will be placed on sale first at New York City, Chicago, Minneapolis and Washington, on May 29th. The stamp is being released simultaneously with the unveiling of the John Ericsson Memorial Statue in Potomac Park, Washington, D. C., on May 29th.

According to a statement issued by the State Department the Crown Prince of Sweden will unveil the statue. Representatives of the leading engineering and allied technical organizations of America have been invited to attend this ceremony. The subject of the stamp will be a replica of the John Ericsson Memorial, designed by the sculptor, James Earle Fraser.

Levy Medal to F. W. Peek, Jr.

Frank W. Peek, Jr., consulting engineer of the General Electric Company in charge of the company's high voltage experimental laboratory at Pittsfield, Mass., was awarded the Levy gold medal by the Franklin Institute of Philadelphia. This award, founded by Louis Edward Levy, was given Mr. Peek in recognition of his paper presented a year ago before the institute on "High-Voltage Phenomena."

Mr. Peek is one of the world's best known figures today in the investigation of artificial lightning and high voltages. He has produced, in the General Electric's laboratory, voltages greater than two million. Outstanding in his research work has been his formation and establishment of laws regarding corona, the investigation of lightning and its effect on high voltage transmission, the study of dielectric phenomena, line insulations and the problems connected with the transmission of high voltage currents.

Obituary

Carl Hering, pioneer electrical engineer and an outstanding figure in today's electrical engineering circles, died suddenly on Monday, May 10th, at the Hahnemann Hospital, Philadelphia, where he had gone to recuperate from what he considered a slight affection of the heart.

Born in Philadelphia in 1860, Doctor Hering's early education was through the schools of that city and in Germany. He quickly became a leader in the technical world, especially in the electrical field in its modern form, which had just sprung into being as he arrived at the age of manhood. In 1880, he graduated from the University of Pennsylvania with a degree of Bachelor of Science and high honors; seven years later, he had conferred upon him the post-graduate degree of M. E. and again, in later years, he received from this same university the honorary degree of Doctor of Science. In 1882, while teaching at the university, he began the study of electrical engineering and in 1883 he published his first technical article, the precursor of a long series of contributions to the profession, including innumerable papers read before the various societies, press articles and no less than eight books. In this same year he was appointed a member of the jury for the international electrical exhibition in Vienna and in the years following he was called upon at least eleven times for similar service both in Europe and at home. There was scarcely an international or otherwise important exhibition associated with the electrical art in which he did not participate. In 1885 he became chief electrical engineer for a German company manufacturing and installing motors and dynamos, but early in 1886 he returned to his native country to practise consulting electrical engineering in the city of Philadelphia. In 1889 he was appointed officer of Public Instruction by the French Government, which, in 1891, made him Knight of the Legion of Honor. Among his many other attainments, Doctor Hering was an enthusiast on the subject of scientific explanation of exceptions to generally accepted physical laws, and through his own personal research, contributed much to the classification of electrical nomenclature. In 1892 he was technical editor of the *Electrical World* and a year later established the "Digest of Current Electrical Literature." For ten years he conducted a department, abstracting notable articles on electrical science in all technical papers of the world. Doctor Hering's work in the electrochemical world began prior to 1890 with extended researches into storage batteries. From these results he obtained numerous patents. He also investigated the regeneration of battery solutions and, in 1900 made electric furnace tests for the reduction of arsenic ore. Some six years later, while designing and operating electric furnaces, he began a series of experiments which resulted in the discovery of a new electromagnetic force to contract a conductor through which current is flowing even to the extent of rupture, when it is fluid. This was known as the "pinch" effect. He also discovered other effects showing that the electromagnetic forces act upon the material of the conductor. In 1909 he applied these forces to impart rapid motion to molten masses and based upon this principle, he invented an electric furnace now in wide commercial use. As early in his career as 1883 he was computing conversion factors for electrical and mechanical energy, publishing a comprehensive treatise on this subject in 1904. A few years later, however, he recalculated all electrochemical equivalents. In 1908 he made exhaustive analyses of the interrelations of various units entering into the calculation of light phenomena and in that same year he described an experiment purporting to demonstrate a hitherto unrecognized factor in electromagnetic induction to show that the well-known Maxwell law of induction should be modified in order to become universal. Doctor Hering was one of the three men to plan and organize the American Electrochemical Society and was also instrumental in founding the *Electrochemical Industry* now *Chemical and Metallurgical Engineering,* published by the McGraw-Hill Publishing Company.

In 1900-1901 he served the Institute as its President; in 1904 he was elected president of the Engineers' Club and in 1906, president of the American Electrochemical Society. Other scientific groups of which he was a valued member are American Association for the Advancement of Science, the Franklin Institute and Illuminating Engineering Society.

At its May 21 meeting, the Board of Directors of the A. I. E. E. passed the following Resolution:

In the death of Dr. Carl Hering on May 10th a distinguished member has been removed from the ranks of the A. I. E. E. pioneers. From eighteen eighty-eight, when he affiliated with the Institute, down through his years of faithful and able service as a committeeman and as President in 1900 and 1901, Dr. Hering stood firmly for the maintenance of Institute ideals. It is with a sense of the great loss sustained that the Board of Directors hereby extends to his family and associates its sincere sympathy, and orders this minute spread upon the records.

Robert Sanford Riley died Friday, May 7, 1926. His death closes a career of much more than usual success not only in his home community but also throughout the entire engineering world. Coupled with high ability, he had high humanity. He led but also served.

Mr. Riley was born in Canada in 1874. His boyhood was spent in Winnipeg. Both his father and mother are descended from a line of old Yorkshire, England. He was graduated with honors in 1896 from Worcester Polytechnic Institute.

He began his business career as an apprentice in a locomotive works. Between 1898 and 1903 Mr. Riley worked his way around the world as a marine engineer starting from Cramp's shipyard in a ship which as draftsman he had helped to design. Sailing the Pacific in the Empress Line, he joined the United States Navy in Hong Kong. He went through the boxer uprising and came home via the Indian Ocean and Suez Canal as chief engineer of the *Arethusa*, a naval auxiliary used as a base ship for torpedo boats. He left the sea to enter the employ of the New York Ship Building Company.

In 1906 Mr. Riley became manager of the American Ship Windlass Co. of Providence, R. I., and here he had an opportunity to put his naval engineering experience to further use in the design of windlasses and steering engines. He soon specialized on the "Taylor" stoker, then being manufactured by the American Ship Windlass Co. in the crude form in which it was left by the death of the inventor. Mr. Riley redesigned and improved the "Taylor" stoker and built up a large business, and became known as a pioneer in the commercial development of high capacity under-feed stokers.

In 1911 Mr. Riley sold out his interests in the American Ship Windlass Co. and later organized the Danford Riley Stoker

Company of Worcester, Mass., to develop and market the Riley Self-Dumping Underfeed stoker.

In July 1918, Mr. Riley's services were called for by the Emergency Fleet Corporation under Chas. L. Schwab. He organized a department for the conducting of trial trips and observing performance in service of boats of the Emergency Fleet Corporation which in January 1919 he turned over to the permanent organization of the Emergency Fleet Corporation.

In 1918 Mr. Riley was elected President of the Worcester Chamber of Commerce and was re-elected in 1919. He was vice-president of the Worcester Y. M. C. A., a member of the A. S. M. E. and served on various of its committees, contributing many valuable papers, he was a member of the Naval Architects and Marine Engineers, the Alpine Club of America, the Appalachian Club, Engineers Clubs of Boston and New York, the Worcester Club, the Tatnuck Country Club, the Detroit Athletic Club. He took an active interest in the movement for the betterment of the city, and was a large contributor to its worthy causes. He gave not only of his money but of his time and energies.

Henry Fleetwood Albright, Fellow of the Institute and since 1917 vice-president of the Western Electric Company, Chicago, died Tuesday, May 11th, after an illness of several months.

Mr. Albright was born in Lancaster, Pennsylvania, October 5th, 1868. Immediately upon his graduation from the Philadelphia High School, he started his technical education under private tutelage and in 1886 entered the employ of the Fuel Gas and Electric Company of Pittsburgh which, at that time, was installing all Westinghouse plants. In 1892 he joined the Western Electric Company as a salesman of electric light and power apparatus in Chicago, and two years later was transferred to its Construction Department in New York, in 1897 becoming plant engineer of the New York factory. His brilliant success and natural aptitude led, in 1899, to his advancement to the position of general manager, and eight years later he received his appointment as general superintendent of the company's manufacturing plants. Shortly thereafter, he again removed to Chicago, where he was largely responsible for the building of the Hawthorne Works of the Western Electric Company, starting its development on a prairie site on the outskirts of Chicago in 1904 and developing it into the largest telephone factory in the world. Almost forty thousand men and women were employed and Mr. Albright's outstanding contribution to it was scientific factory planning and management. At the time of his death he was head of all the company's manufacturing and plant engineering activities.

Closely coupled with his managerial and scientific ability was his aptitude for making friends, and to this qualification, allied with his natural application and zest to any undertaking, may be attributed Mr. Albright's achieved brilliant success.

Mr. Albright joined the Institute in 1892 in the grade of Associate, but advanced to full Member March 20, 1894 and became a Fellow in 1912, typifying in this, as in all of his activities, his constant progression.

William H. Forde, Associate of the Institute and Electrical Engineer for the Stone & Webster Company, Boston, was killed in an automobile accident at Conowingo, Maryland, May 11th.

Mr. Forde was born in Natick, Mass., February 14, 1893. In 1913 he graduated from the Electrical Engineering course at Sheffield Scientific School, and his first position was light and power solicitor for the El Paso Electric Railway Co. He then became solicitor of light and power for the Electric Company, Milford, Mass., and later spent two years as salesman for the Electric Storage Battery Company, Boston. In July 1912, Mr. Forde was chosen electrical inspector for the Stone & Webster Company, with whom he was still affiliated at the time of his death.

PERSONAL MENTION

W. R. Marshall, formerly branch manager for the Westinghouse Company at Buffalo has been selected for new duties as District Manager, Pittsburgh, Pa.

Henry Eggelhof, Dallas, Texas, was recently appointed exclusive representative for the Eastern half of Texas by the Uehling Instrument Co. of Paterson, N. J.

Erwin G. Fleming has been transferred from the Central Station Engineering Dept. of the General Electric Company, Schenectady to the Jacksonville, Fla. office. Mr. Fleming will stay at Miami.

C. W. Stokes has joined the organization of the American Brown Boveri Electric Corporation and will be connected with their Chicago office. He was formerly Canadian manager for the English Electric Co., Ltd., and also for a number of years manager for the Sterling Engineering Co., Montreal, Canada.

L. C. Brooks, who has been identified with the Electrical Marine Industry since the first electric ships (The U. S. S. *Kearsage* and *Kentucky* built at Newport News in 1900) and whose resignation as Electrical Engineer of the Bethlehem Shipbuilding Corporation was recently announced, may now be addressed at Groton, Mass. He is taking a much needed rest before forming other business connections, but in the meantime will continue his interests along marine lines. Mr. Brooks has served as chairman of the Institute Committee on Application to Marine Work.

Addresses Wanted

A list of names of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

1.—William E. Ames, Detroit Edison Co., Detroit, Mich.
2.—H. R. Bailey, Electric Bldg., Portland, Ore.
3.—J. Roy Barclay, 3424 Harrison St., Kansas City, Mo.
4.—Hubert L. Clary, 782 West 24th St., Milwaukee, Wis.
5.—J. F. Clinton, 3682 Broadway, New York, N. Y.
6.—J. E. Contesti, 350 W. 58th St., New York, N. Y.
7.—Hugh Denehy, The Inst. of Elect. Engrs., Savoy Pl., Victoria Embankment, London W. C. 2. Eng.
8.—Ralph Elsman, 120 Broadway, New York, N. Y.
9.—Charles A. Foust, 10505 93rd St., Woodhaven, N. Y.
10.—George Frasher, 1209 So., 4th Ave., Louisville, Ky.
11.—S. Alden Griffin, 19 Elliott St., Springfield, Mass.
12.—Harold G. Haines, 7416 Sylvester, Detroit, Mich.
13.—William A. Hincy, Colonial Apts., Media, Pa.
14.—Elmer D. Johnson, 1481 Harvard St., Washington, D. C.
15.—John E. Lewis, 376 Meyran Ave., Pittsburgh, Pa.
16.—F. A. Lindlof, 610 So. Spring St., Los Angeles, Calif.
17.—Charles W. Lueek, 1454 First Ave., New York, N. Y.
18.—Charles W. Magee, c/o Pelser, 210 West 102nd St., New York, N. Y.
19.—Shu-Sing Man, 541 West 124th St., New York, N. Y.
20.—J. A. McDermott, Y. M. C. A., Lima, Ohio.
21.—Irving Menschik, c/o Dublier Cond. & Radio Corp., 48 W. 4th St., New York, N. Y.

22.—Erwin H. Mitchell, c/o Schmeltz, 481 6th St., Brooklyn, N. Y.
23.—Robert H. Russell, 1128 Warren West, Detroit, Mich.
24.—Lieut. A. G. Scott, 68 West 107th St., New York, N. Y.
25.—Kermit G. Seaman, P. O. Box No. 68, Boulder, Colo.
26.—A. B. Smedley, c/o Cooper Hewitt Elec. Co., 1406 First Nat'l. Bank Bldg., Cincinnati, Ohio.
27.—C. D. Smith, 857 St. Charles St., New Orleans, La.
28.—Will M. Strickler, 301 Detroit Life Bldg., Detroit, Mich.
29.—O. G. Utt, 4738 Oak St., Kansas City, Mo.
30.—Leo A. Van Etsen, 1100 Park Ave., New York, N. Y.
31.—John D. Walker, 2686 Woodstock Ave., Swissvale, Pa.
32.—A. R. Williamson, 561 Delaware Ave., Norwood, Pa.
33.—C. A. Winder, Southern Equipment Co., San Antonio, Texas.

Book Review

NEW HANDBOOKS OF THE BUREAU OF STANDARDS

Handbooks No. 6 and No. 7, giving Safety Rules for the Installation and Maintenance of Electrical Supply Stations and Electric Utilization Equipment, respectively, are now on distribution through the Bureau of Standards, Washington. Price 10 cents each. These are published in small 5-in. by 7-in. paper covered pamphlets No. 6 comprising Part I the Grounding Rules of the fourth edition of the National Electrical Safety Code, while No. 7 consists of Part III and the Grounding Rules of the fourth edition of the National Electrical Safety Code. Publication dates, February 5 and March 12, 1926, respectively. Address Superintendent of Documents, Government Printing Office, Washington, D. C.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES (MAY 1-30, 1926)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

CRYSTALLINE FORM AND CHEMICAL CONSTITUTION.

By A. E. H. Tutton. Lond. & N. Y., Macmillan & Co., 926. 252 pp., illus., diagrs., tables, 9 x 6 in., cloth. $3.60.

An account of the present position of chemical crystallography, based upon a course of lectures delivered at Cambridge University. The book is intended primarily for students of chemistry, physics or mineralogy, but an introductory chapter which summarizes the essential facts of pure crystallography renders it available to readers unfamiliar with the subject.

AUSGEWAHLTE METHODEN FUR SCHIEDSANALYSEN UND KONTRADIKTRISCHES ARBEITEN BEI DER UNTERSUCHUNG VON ERZEN, METALLEN UND SONSTIGEN HUTTENPRODUKTEN....

By Gesellschaft Deutscher Metallhutten-und Bergleute. Berlin, The Society, 1926. (Mitteilungen, t. 2). 146 pp., 9 x 6 in., boards. $2.50.

A collection of methods for the chemical analysis of metals and ores, recommended by the Chemical Section of the Society of German Metallurgists and Miners for umpire analyses. The methods cover the examination of zinc, zinc ash and zinc ores; cadmium; nickel, nickel ores and alloys; cobalt and bismuth, and their ores and alloys; lead compounds; magnesium and its alloys; corundum and carborundum; and the secondary ingredients in antimony and its ores. A chapter on proper methods of sampling is included.

APPAREILLAGE ELECTRIQUE.

By P. Maurer. Paris, Gauthier-Villars et Cie., 1926. 317 pp., illus., diagrs., tables, 10 x 6 in., paper. 55 fr.

A text-book on apparatus for interrupting, protecting, regulating and distributing electricity. The treatment is largely descriptive and treats of the design and use of switches, circuit-breakers, rheostats and switch-boards of the commercial types in use in France.

DICTIONARY OF APPLIED CHEMISTRY, v. 6.

By Sir Edward Thorpe. Revised & enlarged edition. Lond. & N. Y., Longmans, Green & Co., 1926. 791 pp., illus., diagrs., 9 x 6 in., cloth. $20.00.

The death of Sir Edward Thorpe, in February, 1925, interrupted the completion of the Dictionary, but publication is now resumed under the editorship of Dr. H. Forster Morley, and it is hoped to complete the work during 1926.

The present volume includes a number of lengthy articles on substances of great industrial importance, prepared by competent authorities. Saponification, silver, soap, sodium and its salts, starch, sugar, sulfur, sulfuric acid, synthetic drugs, tannins and tantalum are thus treated, together with many others. The new edition easily maintains the work in its rank as the leading English encyclopedia of industrial chemistry.

FUNDAMENTAL CONCEPTS OF PHYSICS IN THE LIGHT OF MODERN DISCOVERY.

By Paul R. Heyl. Balt., Md., Williams & Wilkins Co., 1926. 112 pp., 7 x 5 in., cloth. $2.00.

An account of the evolution of our present concepts through the eighteenth, nineteenth and twentieth centuries. Dr. Heyl studies the antecedents of present views, tracing correlations, analogies and similarities wherever they are found, and regarding the concepts in their philosophical aspects. The book is an interesting, non-mathematical description, accompanied by a list of references to more detailed works.

GUTERUMSCHLAG.

Die Guterumschlag-Verkehrswoche des V. D. I. in Düsseldorf und Köln, 1925. Sonderausgabe der Zeitschrift des V. D. I. Berlin, V. D. I. Verlag, 1926. 256 pp., illus., diagrs., 11 x 8 in., paper. 30.-rm.

In September, 1925, a week-long conference on the problems of freight traffic was held in Düsseldorf and Cologne under the auspices of the Verein Deutsche Ingenieure. The papers presented appeared in the V. D. I. Zeitschrift and are now collected in the present volume.

While questions of railroad freight handling are most extensively treated, there are papers on boat traffic, harbor machinery, street and light railroads, motor-truck and airship freight handling. Special attention is given to loading and unloading machinery and to the efficient utilization of equipment.

HERTHA AYRTON; a Memoir.

By Evelyn Sharp. London., Edward Arnold & Co., 1926. 304 pp., illus., port., 9 x 6 in., cloth. $5.50. (Gift of Longmans, Green & Co., N. Y.)

Mrs. Ayrton's chief interest to engineers arises from her investigations of the electric arc, which were published in book form in 1902. In 1899 she was elected a member of the Institution of Electrical Engineers, being the first woman to attain that distinction. She also engaged in an investigation of the formation of sand ripples, which led her, during the War, to the invention of the Ayrton fan, a device for driving back poison gas.

Her biographer traces her career from early childhood to her death in 1923.

INTRODUCTION TO INDUSTRIAL CHEMISTRY

By S. I. Levy. N. Y., McGraw-Hill Book Co., 1926. 288 pp., illus., diagrs., 8 x 6 in., cloth. $4.00.

Dr. Levy's book departs from the usual textbook on industrial chemistry, which deals with the specialized technique of particular branches of chemical industry. Instead, he offers a general introduction to the whole subject, in which are discussed such matters as costing, methods of heating, cooling, pulverizing, filtering, extracting, distilling, drying, etc., on a large scale, and the transporting and handling of gases and liquids. The presentation of these foundation processes is supplemented by brief accounts of certain selected industries; fuel, sulfuric acid, alkali, intermediates and explosives. The book is intended to bridge the gap between the methods of the laboratory and those used industrially.

LOKOMOTIVVERSUCHE IN RUSSLAND.

By G. Lomonossoff. Berlin, V. D. I. Verlag, 1926. 330 pp., illus., diagrs., tables, 12 x 9 in., cloth. 42.-mk.

In the years 1898 to 1900, Professor Lomonossoff devised a method for testing locomotives, by which the engine was subjected to the working conditions customary for laboratory tests, on the actual roadway instead of in the laboratory. Wind resistance and the jolting from passage over the rails here introduce factors absent from laboratory tests.

Since 1908 the method has been used in Russia to investigate each new type of locomotive. The present work presents some of the results of tests made from 1908 to 1923.

The purpose and method of testing is first explained. The eight types of locomotives tested are then fully described, after which the results of tests on a locomotive of the newest Russian type are given in detail. The most important results of the tests of the remaining types of locomotives are then given. The final chapter illustrates the use of the experimental results for the solution of problems of locomotive operation.

METHODS OF MEASURING TEMPERATURE.

By Ezer Griffiths. 2nd edition. Lond., Charles Griffin & Co.; Phila., J. B. Lippincott Co., 1926. 203 pp., illus., tables, 9 x 6 in., cloth. 10s 6d.

Written for those concerned with the measurement of temperature in scientific investigations or in industrial operations. Attention is given chiefly to the experimental basis of the methods in general use, the calibration of the instruments and the precautions to be observed in practice.

A connected account of the classical researches with the gas thermometer is given. Subsequent chapters deal with the mercury thermometer, the resistance thermometer, the thermocouple, the radiation pyrometer and the optical pyrometer. References are appended to each chapter.

The changes in this edition are, in addition to the correction of errata, chiefly in the portion on optical pyrometry.

POWER-FACTOR WASTES.

By Charles R. Underhill. N. Y., McGraw-Hill Book Co., 1926. 326 pp., illus., diagrs., tables, 9 x 6 in., cloth. $3.50.

This discussion of power-factor wastes is intended to present the subject from many points of view and thus to direct more attention to their importance. It aims to acquaint those responsible for these wastes with their causes, their cost and their cures. Many chapters are contributed by specialists on their subjects.

PYROMETERS.

By Ezer Griffiths. Lond. & N. Y., Isaac Pitman & Sons, 1926. 126 pp., illus., diagrs., tables, 7 x 5 in., cloth. $2.25.

Intended as a connecting link between textbooks on heat and advanced treatises on pyrometry, this little book describes recent pyrometric apparatus, including expansion thermometers, thermoelectric pyrometers, resistance thermometers, optical and total radiation pyrometers. Only a few types of each class are described, but these have been selected from outfits designed to meet unusual requirements.

RAILROAD ELECTRIFICATION AND THE ELECTRIC LOCOMOTIVE.

By Arthur J. Manson. 2nd edition. N. Y., Simmons-Boardman Publishing Co., 1925. 332 pp., illus., diagrs., tables, 9 x 6 in., cloth. $4.00.

Intended to provide information of value to those concerned with the operation and maintenance of electric locomotives, or interested in the general subject of railroad electrification. Technical detail is reduced to small dimensions, but the fundamental units and principles of electricity are explained, the design and construction of electric locomotives are described and illustrated, and the solutions of a number of practical problems incident to electrification are given. An appendix gives a brief history of electrification in the United States.

TOPOGRAPHICAL DRAWING NOTES.

By G. P. Schubert. 2nd edition. Houghton, Mich., Michigan College of Mines, 1926. 82 pp., 11 drawings & diagrs., 6 x 9 in., cloth. $1.65.

This textbook supplements the lectures and laboratory work in a course on topographical drawing and traverse computations given at the Michigan College of Mines. It treats various methods of calculating and plotting traverses and of drawing suitable topographic maps. The course is planned to enable surveyors and mining engineers to do as much of this class of work as they may be called upon to do in their regular practice.

Past Section and Branch Meetings

SECTION MEETINGS

Boston

Modern Methods of Combustion Control, by E. G. Bailey, Bailey Meter Co. Joint meeting with A. S. M. E. April 15. Attendance 150.

The Art of Making Good Concrete, by W. C. Voss, Portland Cement Association; E. S. Larned, Civil Engineer, and J. G. Ahlers, Barney-Ahlers Construction Corp. Joint meeting. April 21. Attendance 228.

Chicago

Automatic Stations and Their Remote Supervision, by Chester Lichtenberg, General Electric Co. Joint meeting with Western Society of Engineers. May 3. Attendance 200.

Cincinnati

Modernizing Industrial Control Apparatus, by G. O. Wilms, Allen-Bradley Company. April 8. Attendance 84.

Cleveland

Industrial Motor Bearings from a Maintenance Point of View, by H. G. Veit, National Malleable Castings Co.;

Large Synchronous Motors for Industrial Drives, by P. C. Jones, Goodyear Tire and Rubber Co., and

Some Design Features of Industrial Motors, by E. E. Dreese, Lincoln Electric Co. April 22. Attendance 93.

Connecticut

Relativity and the Einstein Theory, by W. B. Hall, Yale University. April 29. Attendance 65.

Denver

Operation of D-C. Motors on Direct and Alternating Current Simultaneously, by Edwin Heath, University of Colorado;

Some New Developments in High-Voltage Insulators, by P. M. Brown, University of Colorado; and

The Application of Vacuum Tubes to Magnetic-Flux Measurements, by K. A. Browne, University of Colorado. April 16. Attendance 70.

Engineering in Russia, by S. M. Marshall, Perine and Marshall. April 22. Attendance 28.

Detroit-Ann Arbor

Power from Mercury Vapor, by W. L. R. Emmet, General Electric Co. Illustrated by slides and motion picture. March 16. Attendance 200.

Inspection trip to River Rouge Plant of the Ford Motor Company. April 3. Attendance 50.

Power Factor, What Is It and What Can We Do About It, by E. L. Bailey, Sales Engineer. Joint meeting with Detroit Engineering Society. April 23. Attendance 175.

Erie

Oil-Electric Locomotives, by Herman Lemp, Consulting Engineer. Illustrated with slides. Joint meeting with A. S. M. E. and A. C. S. April 20. Attendance 200.

Fort Wayne

The Consolidation of the Traction Company with the Insull Properties, by R. M. Fuestel, Indiana Service Corporation. Illustrated with motion pictures. April 28. Attendance 54.

Indianapolis-Lafayette

The Development of Steam Generators and Radiant Heat, by G. A. Orrok. Joint meeting with A. S. M. E. April 20. Attendance 119.

Ithaca

Finding and Filling Your Place in Industry, by C. R. Dooley, Standard Oil Company of New Jersey. March 15. Attendance 200.

Lightning and High-Voltage Phenomena, by F. W. Peek, Jr., General Electric Co. April 14. Attendance 70.

The Social and Economical Aspect of Niagara Falls Power, by W. K. Bradbury. May 7. Attendance 130.

Kansas City

Light Radiations as Shown by the Spectroscope, by F. E. Johnson, Kansas University Engineering School;

Loop Feeders of the Kansas City Power and Light Company, by W. O. Edmonds, Kansas City Power and Light Co., and

Super Power Systems, by B. J. Denman, United Light and Power Co. March 31. Attendance 48.

Lightning Protective Devices, by A. L. Atherton, Westinghouse Electric and Mfg. Co. The following officers were elected: Chairman, R. L. Baldwin; Secretary, S. M. DeCamp. April 30. Attendance 51.

Los Angeles

Modern Developments in Astronomical Research, by Ferdinand Ellerman, Mount Wilson Observatory. Illustrated. May 4. Attendance 150.

Lynn

The Industrial Conditions of the Nation, by D. S. Kimball, Cornell University, and

The Activities of Lynn, by Hon. Ralph S. Bauer, Mayor. March 20. Attendance 184.

Mexico

Maximum-Demand Meters, by Solis Payan. May 6. Attendance 18.

Milwaukee

The Mechanical Engineer in the Large Industries Today, by O. A. Anderson, Armour and Company. March 17. Attendance 70.

The Tremendous Responsibilities Which Confront the Engineer, by Roy Wright, Vice-President, A. S. M. E. April 21. Attendance 60.

Minnesota

Transmission of Pictures over Wire, by R. D. Parker, American Telephone and Telegraph Co. April 26. Attendance 150.

Nebraska

Tasks Ahead in Engineering Education, by O. J. Ferguson, University of Nebraska. April 9. Attendance 35.

Niagara Frontier

Automatic Train Control, by W. H. Reichard, General Railway Signal Company. The following officers were elected: Chairman, H. B. Alverson; Secretary-Treasurer, A. W. Underhill, Jr. April 30. Attendance 42.

Philadelphia

Progress, by L. F. Deming, General Electric Co. Illustrated with slides. April 12. Attendance 105.

Pittsburgh

Lightning, by F. W. Peek, Jr. Illustrated with slides and motion picture. The election of the following officers was announced: Chairman, W. C. Goodwin; Secretary, D. M. Simons. May 11. Attendance 385.

Pittsfield

Annual Dinner, held at the Hotel Wendell. The speakers were: C. C. Chesney, President-Elect of the A. I. E. E.; H. M. Hobart, Vice-President-Elect in District No. 1; Harold B. Smith, Vice-President in District No. 1; E. D. Eby, Chairman of the Pittsfield Section, and Dr. J. J. Walsh of Brooklyn, N. Y. Entertainment was furnished by the Radio Four Quartet, the Kilowatt Orchestra—an orchestra composed of electrical engineers, and Harold B. May's dance orchestra. The program was broadcast through WGY. March 30. Attendance 309.

Inspection trip to the Schenectady Works of the General Electric Company. April 19. Attendance 350.

Portland

The Influence of Line Voltage upon Induction-Motor Characteristics, by C. H. Bjorquist and H. E. Rhoads;

The Effect of Three-Phase Transformer Connections on Induced Harmonics, by D. O. Bergey, E. E. Kearns and C. W. Leihy, and

The Characteristics of Distribution Transformers at High Overloads, by F. C. Mueler, C. R. McLean, B. E. Plowman, O. W. Hurd and W. W. Bonar. These papers were presented by senior students of the Oregon Agricultural College. A demonstration of first-aid methods was also given by members of the Pacific Telephone and Telegraph Co. April 9. Attendance 135.

Providence

Fundamental Considerations of Power Limits of Transmission Systems, by R. E. Doherty, General Electric Co. Joint meeting with A. S. M. E. and Providence Engineering Society. April 8. Attendance 35.

Most Recent Radio Developments, by E. L. Bowles, Massachusetts Institute of Technology. The following officers were elected: Chairman, E. E. Nelson; Vice-Chairman, F. N. Tompkins, and Secretary-Treasurer, F. W. Smith. April 20. Attendance 60.

San Francisco

Manufacture, Treatment and Testing of Special Alloy Steels, by G. A. Richardson. Joint meeting with A. S. M. E., A. S. C. E. and Chemical Society. April 14. Attendance 250.

Engineering Education—Its History and Prospects, by H. H. Henline, Stanford University. April 23. Attendance 80.

St. Louis

The Position of Capital in the Electrical Industry, by W. A. Layman, Wagner Electric Corp. September 16. Attendance 122.

Lightning, by E. E. F. Creighton, General Electric Co. October 23. Attendance 275.

The Klydonograph and Its Application, by J. H. Cox, Westinghouse Electric and Mfg. Co. November 18. Attendance 102.

Engineering Research, by B. L. Newkirk, General Electric Co. December 16. Attendance 200.

Long-Distance Cable Communication, by H. H. Nance, American Telephone and Telegraph Co. January 20. Attendance 162.

Dance. Joint with A. S. M. E. February 17. Attendance 205.

Development of Electric Power Generation and Distribution, by Col. Peter Junkersfeld, McClellan and Junkersfeld. March 17. Attendance 180.

Automatic Stations, by C. A. Butcher, Westinghouse Elec. & Mfg. Co. April 21. Attendance 60.

Schenectady

The Relation between Technical and Business Training, by J. G. Callan, Harvard College of Business Administration. April 16. Attendance 350.

Seattle

Cost Analysis of Engineering Problems, by E. G. Champreux, The Pacific Telephone and Telegraph Co. The following officers were elected: Chairman, C. E. Mong; Secretary-Treasurer, C. R. Wallace. April 21. Attendance 81.

Sharon

Steel-Mill Electrification, by G. E. Stoltz, Westinghouse Electric & Mfg. Co. May 4. Attendance 101.

Spokane

Automatic Train-Control Equipment, by R. C. Charlton, Oregon-Washington Railroad and Navigation Co. April 23. Attendance 40.

Saskatchewan

Annual Meeting. The following officers were elected: Chairman, S. R. Parker; Secretary-Treasurer, W. P. Brattle. April 15.

Springfield

Automatic and Supervisory Controlled Substation, by R. J. Wensley, Westinghouse Elec. & Mfg. Co. April 20. Attendance 100.

Toronto

High-Power Laboratory of the Westinghouse Electric and Manufacturing Company, by W. R. Woodward. April 23. Attendance 300.

Toronto—Past and Present, by T. A. Reed. The following officers were elected: Chairman, M. B. Hastings, Secretary, F. F. Ambuhl. May 7. Attendance 63.

Utah

Loud-Speaker Horns, by J. V. Laird;

Electro-Chemical Reduction of Metals, by S. M. Young;

A Proposed Railway Electrification, by C. E. Hoffman;

Characteristics of Vacuum Tubes, by I. S. Pierson; and

Automatic Control of Substations, by A. LaMont Nelson. These papers were furnished by students of the University of Utah. April 28. Attendance 22.

Vancouver

Some Recent Developments in Urban Transportation, by H. M. Lloyd, British Columbia Electric Railway Co., Ltd. April 6. Attendance 26.

Washington

Developments in Motor-Vehicle Headlighting, by Lieut-Col. R. E. Carlson, Bureau of Standards. The following officers were elected: Chairman, C. A. Robinson; Vice-Chairman, M. G. Lloyd; Secretary-Treasurer, D. S. Wegg. May 11. Attendance 38.

Worcester

Electrical Reproduction of Music, by H. H. Newell, Worcester Polytechnic Institute. May 5. Attendance 80.

BRANCH MEETINGS

Alabama Polytechnic Institute

Business Meeting. The following officers were elected: Chairman, J. D. Stewart; Vice-Chairman, W. L. Garlington; Secretary-Treasurer, I. L. Knox. April 21. Attendance 22.

The Application of the X-Ray to Industry, by Dr. Fred Allison. May 5. Attendance 52.

University of Arizona

Power-Distribution Practise, by B. L. Jones;

Mine Lighting, by S. A. Sinclair, and

Underground Power Installation, by W. T. Wishart. April 10. Attendance 18.

University of Arkansas

Engineering English, by Dr. Jones. November 3. Attendance 32.

Natural-Period Vibration of Machinery, by Prof. Theorle, and

Equipment of a Modern Power Plant, by E. Reynolds. November 17. Attendance 28.

Power Distribution, by A. S. O'Bar;

Benefits of Engineering Organization, by B. A. Avery, and

Production of Casing-Head Gas, by E. T. Martin. December 1. Attendance 28.

Carrier Waves in Telephony, by R. A. Austin, and

Economy in Modern Steam Locomotives, by F. H. Smith. January 19. Attendance 20.

Gas-Engine Electric Railways as Used in England, by Frank Lane, and

Engineering Exhibit at Arkansas State Fair, by J. F. Toohey. February 2. Attendance 25.

Improved Methods of Combustion, by Prof. Strate. April 7. Attendance 11.

Development and Use of Searchlights, by Russell McFarland, and

Automobile Lights, by Elmer Nichols. April 20. Attendance 14.

High-Frequency Apparatus, by E. F. Nichols. The following officers were elected: President, Carroll Walsh; Vice-President, C. W. Collier; Secretary-Treasurer, W. H. Mann. May 4. Attendance 15.

Armour Institute of Technology

Smoker. April 14. Attendance 71.

Business Meeting. The following officers were elected: Chairman, M. T. Goetz; Secretary, C. W. Schramm; Treasurer, C. W. Burcky. May 6.

Brooklyn Polytechnic Institute

Motion pictures, entitled respectively "Revelations by X-Ray," "Endurance Tests of Induction Motors," and "Manufacture of Okonite Cables," were shown. April 14. Attendance 45.

California Institute of Technology

Business Meeting. April 27. Attendance 23.

Inspection trip to the Shrine Temple in Los Angeles. April 30. Attendance 12.

University of California

Inspection trip to P. T. & T. Co. January 29. Attendance 30.

Inspection trip to G. & E. Co. Broadcasting Station KGO. February 9. Attendance 45.

Inspection trip to P. T. & T. Co. March 17. Attendance 25.

Business Meeting. April 14. Attendance 31.

Case School of Applied Science

The Application of Carbon Products to Industry, by P. D. Manbeck, National Carbon Co., Inc. April 27. Attendance 38.

Catholic University of America

Radio, by B. J. Kroeger. Illustrated with slides. April 22. Attendance 21.

University of Colorado

Operation of a Series Motor with A-C. and D-C. Simultaneously, by Edwin Heath;

High-Voltage Insulators, by P. M. Brown. Illustrated with slides.

The Measurement of Magnetic Flux by the Use of the Vacuum Tube, by Kenneth Brown. April 16. Attendance 50.

University of Florida

Construction and Operation of Gas-Electric Busses, by F. P. Dean, and

Early Development of Steam Engine, by G. C. Robertson. April 26. Attendance 15.

Georgia School of Technology

Business Meeting. The following officers were elected: President, W. M. McGraw; Secretary-Treasurer, F. L. Kaestle. April 20. Attendance 45.

State University of Iowa

The Selenium Cell and Its Uses, by A. J. Plath. and

The Cathode-Ray Oscillograph, by R. B. Prunty. April 14. Attendance 34.

Wind Power, by Theo. Van Law;

Atomic-Hydrogen Arc Welding, by R. C. Van Ness, and

Insulating Materials Used in Transformers, by R. H. Perry. April 21. Attendance 33.

A motion picture, entitled "Coal is King," was shown. April 28. Attendance 35.

Patent Laws, by G. Gunderson, and

110-Volt Filamentless Vacuum Tube, by N. Jensen. May 5. Attendance 36.

Kansas State College

The Theory of Electrostatic and Electromagnetic Fields, by E. R. Lyons. January 12. Attendance 83.

Synchronous Machinery and Equipment, by E. S. Henningsen, General Electric Co. March 4. Attendance 98.

Growth of Utilities, by Arthur Groesbeck, United Light and Power Corp. April 12. Attendance 72.

Public-Utility Publicity, by H. W. Davis. April 27. Attendance 55.

Lafayette College

Talks were given by C. L. Craven and P. O. Farnham. March 31. Attendance 21.

Inspection trip to Lehigh Telephone Company's Central Station in Easton, Pa. April 7. Attendance 20.

The Use of Compressed Air in Industry, by A. H. Taylor, Ingersoll-Rand Co. April 28. Attendance 21.

Lehigh University

Some Problems of the Electrical Industry, by L. W. W. Morrow, Managing Editor, *Electrical World*, and

Organization and Operation of a Public Utility, by Chas. Zug, Jr., student. March 11. Attendance 49.

Recent Developments in Electric Traction, by J. D. Alrich, General Electric Co. A motion picture, entitled "Electrification of the Mexican Railroad," was shown. April 15. Attendance 66.

Lewis Institute

The Use of Mercury-Arc Rectifiers in Substations, by R. B. Freston. April 30. Attendance 18.

Massachusetts Institute of Technology

The Outlook for the Electrical Engineer Now in College, by Dr. E. W. Wickenden, Society for the Promotion of Engineering Education. April 23. Attendance 22.

University of Michigan

A film, showing the Okonite method of manufacturing insulated wires and cables, was shown. April 26. Attendance 30.

School of Engineering of Milwaukee

Standing Waves at Ultra-Radio Frequencies, by Ben Chromy. A motion picture, entitled "White Coal," was shown. April 20. Attendance 41.

Inspection trip to the Nash Motors Corporation. April 28. Attendance 40.

Motion pictures, entitled "The Audion" and "The Go-Getter," were shown. May 11. Attendance 25.

University of Minnesota

The Application of Synchronous Machines, by C. W. Place General Electric Co. March 9. Attendance 75.

Montana State College

Diesel-Electric Drive for Dredges, by B. W. Crowell, and

Lighting-Generator Research, by R. K. Frazier. April 8. Attendance 159.

The Graduate Engineer and His Relation to the Industries, by Mr. Caples, The Anaconda Copper Mining Co. April 12. Attendance 172.

Modernized Dipping and Baking, by S. Thompson, and

Electric Refrigeration, by H. F. Dehler. May 6. Attendance 147.

University of Nevada

Business Meeting. The following officers were elected: President, George Fairbrother; Secretary-Treasurer, Cornelius Fort. April 26. Attendance 20.

College of the City of New York

Inspection trip to Interborough Power Plant. March 30. Attendance 23.

Electric Wave Filters, by A. Granich, Bell Telephone Laboratory. Illustrated with slides. April 22. Attendance 41.

Business Meeting. May 6. Attendance 13.

New York University

Business Meeting. October 15. Attendance 21.

Opportunities for the Electrical Engineering Graduate, by Dr. L. L. Arnold. October 29. Attendance 28.

Business Meeting. November 13. Attendance 32.

Distortion in Radio Receiving Sets and Loud Speakers, by A. Senauke. December 11. Attendance 19.

Turbo-Alternators, by J. Hemingson, General Electric Co. January 15. Attendance 42.

Business Meeting. April 20. Attendance 21.

Distortion Causes in Audio-Frequency Amplifiers, by Alexander Senauke, Popular Science Radio Laboratory. April 22. Attendance 27.

University of North Carolina

The Automatic Telephone, by J. C. Fred, student. February 25. Attendance 31.

A-C. Measurements with the Electron Tube, by J. D. Finklea. March 8. Attendance 26.

The Power Possibilities of Muscle Shoals, by H. C. Klingenschmitt. April 1. Attendance 28.

Interesting Phases of the Electrical Engineering Profession, by T. J. McManis, General Electric Co. Illustrated with slides. April 26. Attendance 54.

University of North Dakota

Electrification of the Virginia Railroad, by Leonard Dagen;

The Electrical Stethophone, by Thore Hawk, and

The Life of Michael Faraday, by H. W. Augustadt. April 19. Attendance 17.

Northeastern University

Inspection trip to the Simplex Wire and Cable Company. April 2. Attendance 40.

Dangers of Electrical Shocks, by A. E. Kennelly, Harvard University. April 29. Attendance 64.

Ohio Northern University

Business Meeting. October 14. Attendance 47.

Protective Apparatus, by Mr. Roth. November 19. Attendance 22.

Business Meeting. January 20. Attendance 23.

The Application of Electric Power to Auxiliary Drives in Central Stations, by Prof. I. S. Campbell. April 14. Attendance 20.

The Application of the Compound-Interest Formula to the Various Sciences, by Prof. Whitted. April 28. Attendance 21.

Ohio State University

A motion picture, entitled "Wizardy of Wireless," was shown. April 30. Attendance 112.

Opportunities for Engineers in Public-Utility Work, by E. C. Stone, Duquesne Power and Light Co. Joint meeting with A. S. M. E. May 7. Attendance 52.

Oklahoma Agricultural and Mechanical College

Business Meeting. October 21. Attendance 66.

The Telephone Business, by Mr. Boone. Four reels of motion pictures were shown. April 21. Attendance 68.

University of Oklahoma

How To Lose Your First Job, by F. G. Tappan. April 15. Attendance 23.

Oregon State Agricultural College

The Influence of Line Voltage upon Induction-Motor Characteristics, by C. H. Bjorquist and H. E. Rhoads;

The Effect of Three-Phase Transformer Connections on Induced Harmonics, by D. O. Bergey, E. E. Kearns and C. W. Leihy, and

The Characteristics of Distribution Transformers at High Overloads, by F. C. Mueller, C. R. McLean, B. E. Plowman, O. W. Hurd and W. W. Bonar. Illustrated with slides. April 9. Attendance 56.

Pennsylvania State College

Electric Locomotives, by O. K. Harlan. Illustrated with slides. Joint meeting with A. S. M. E. March 3. Attendance 60.

Smoker. The following officers were elected: President, F. F. Wilkins; Vice-President, E. H. Basehore; Secretary, E. Huggler; Treasurer, M. I. Allen. April 28. Attendance 45.

University of Pennsylvania

After College, What?, by C. K. West, General Electric Co., and C. H. Wellerjean, Westinghouse Electric and Mfg. Co. February 25. Attendance 62.

Business Meeting. April 14. Attendance 45.

University of Pittsburgh

Crystal Control of Radio Frequencies, by F. C. Hartman, student, and

Experiences at National Tube Co., by G. M. Jarrett, student. March 5. Attendance 24.

The Liberty Bridge, by V. R. Covell, Bureau of Bridges of Alleghany County. March 12. Attendance 24.

George Westinghouse, by D. G. Nesbit, student, and

Railroad-Signal Control, by Chas. Caveny, student. March 19. Attendance 28.

Opportunities with The Duquesne Light Co., by W. F. Young. March 26. Attendance 28.

Homestead Steel Company, by A. S. Brown. April 9. Attendance 25.

Industrial Engineering, by L. P. Alford. April 16. Attendance 26.

Talks by H. J. A. Cramer and E. E. Muerer, students. April 23. Attendance 26.

Talks by E. H. Powell and J. J. Pfeiffer, students. April 30. Attendance 26.

Purdue University

The World of Paper, by P. Y. Tumey, General Electric Co. Illustrated with slides and motion pictures.

Switchboards, by C. C. Adams, General Electric Co. April 13. Attendance 100.

Westinghouse—The Institution, by Prof. L. D. Rowell. April 27. Attendance 35.

Rensselaer Polytechnic Institute

Modern Induction Furnaces, by J. A. Seede, General Electric Co., and

The Design and Operation of Electric Furnaces, by F. W. Brooke, William Swindell and Bros. April 20. Attendance 65.

Rhode Island State College

Stresses in High-Speed Turbines, by Professor Brown. March 29. Attendance 21.

Rutgers University

Finances of the Light and Power Industry, by Mr. Siddons, student, and

The Treating of Telephone and Telegraph Poles, by Mr. Miller, student. April 19. Attendance 19.

South Dakota State School of Mines

Business Meeting. April 1. Attendance 11.

University of Southern California

The Duties of a Power Salesman, by Mr. King, Los Angeles Bureau of Power and Light, and

The Application of Electricity to the Oil Industry, by Mr. Wade. April 15. Attendance 37.

Stanford University

The Pit River Development of the Pacific Gas and Electric Co., by E. A. Crellin. Illustrated with slides. April 20. Attendance 26.

Business Meeting. May 4. Attendance 21.

Stevens Institute of Technology

A motion picture, entitled "Speeding Up Deep-Sea Cables," was shown. A short talk was also given by Lincoln Walsh, student. April 15. Attendance 74.

A film, illustrating the applications of the gyroscope, was shown. a demonstration of the properties of the gyroscope by means of a small model was also given by L. G. Walsh, student. The following officers were elected: Chairman, D. B. Wesstrom; Secretary, Gene Witham. May 4. Attendance 110.

Swarthmore College

Business Meeting. April 15. Attendance 30.

Syracuse University

A motion picture, entitled "Power," was shown. April 12. Attendance 19.

Automatic Railway Substations, by W. H. H. Wilkinson. April 19. Attendance 19.

Agricultural and Mechanical College of Texas

Electrical Show, produced by the students. In connection with the show the Southwestern Bell Telephone and Telegraph Company held a pageant showing the development of the telephone for the last 50 years. April 10. Attendance 1000.

Problems of Independent Telephone Companies of Today, by R. B. Still, Association of Independent Telephone Companies of Texas. May 7. Attendance 84.

University of Texas

A motion picture on Automatic Substation Control was shown. April 8. Attendance 23.

Business Meeting. April 22. Attendance 8.

Virginia Military Institute

The Socket Power Supply for Radio Receivers, by W. R. Noble. Motion picture, entitled "The Queen of the Waves," was shown. December 22. Attendance 19.

A motion picture, entitled "The King of the Rails," was shown. February 15. Attendance 47.

University of Virginia

Motion pictures, entitled "The King of the Rails," and "The Panama Canal," were shown. April 19. Attendance 16.

Communication from Moving Trains, by Jean Roberts. Motion pictures, entitled "The Go-Getter," and "The Queen of the Waves," were shown. May 3. Attendance 20.

University of Washington

The Design of Telephone Pole Lines, by Mr. Freed, Pacific Telephone and Telegraph Co. April 7. Attendance 22.

Worcester Polytechnic Institute

The Telephone, by Captain J. C. Fair, New England Telephone and Telegraph Co. April 21. Attendance 28.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.
53 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.
57 Post St., San Francisco, Calif., N. D. Cook, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to ***EMPLOYMENT SERVICE, 33 West 39th Street, New York City,*** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

ELECTRICAL SWITCH DESIGNER, for automatic control of direct- and alternating-current motors. Opportunity. Apply by letter stating technical training, experience, age and required salary. Location, New York City. R-9039.

ELECTRICAL ENGINEER GRADUATES, two, with several years' experience, for distribution department of large public utility. Opportunity to enter commercial sales department. Experience in overhead distribution layout and estimating desirable. Opportunity. Apply by letter with complete details of age, education, training, experience and salary desired with recent photograph. Location, Middle Atlantic. R-9727-C.

INSTRUCTOR, electrical engineering graduate, under 30, to instruct in lecture room and laboratory educational department of large eastern public utility. Some experience in pedagogy and the electrical industry essential. Apply by letter, stating education, experience, age, salary expected, and other details. Location, New York City. R-9068.

MEN AVAILABLE

1925 GRADUATE ELECTRICAL ENGINEER, Georgia Tech., age 24, sales and business experience. Desires position with possibilities for advancement with public utility or electrical contracting company. Location, preferably Florida or Georgia. C-2004.

PLANT ENGINEER, MECHANICAL SUPERINTENDENT OR MASTER MECHANIC, mechanical engineer, age 40, with fifteen years' experience in the above, desires an opening with a progressive concern. Prefers location in Eastern or Central states. C-1182.

ELECTRICAL ENGINEER with wide and thorough experience in America and Europe, desires position as executive or chief electrical engineer. Competent in electrical and mechanical design of electrical machinery; made special study of gasoline electric automotive vehicles. Familiar with research work in electrical, mechanical and physical problems. East preferred. Minimum salary $6600. C-693.

ENGINEER, age 36, married, graduate M. E. and E. E., wide range of engineering experience, and especially well qualified in public utility electrical engineering, power plants, sub-station lines. Highly trained technically, but prefers position requiring combination of technical and executive ability. Available in two to four weeks. Location, United States. B-5842.

ELECTRICAL ENGINEER, age 32, married, technical graduate, ten years' experience in construction, maintenance and hydroelectric work with prominent companies here and in Venezuela, South America. Desires permanent position in Spanish speaking country. Available on short notice. C-917.

ELECTRICAL ENGINEER, four years' design and development experience with large manufacturing company. Would like similar work with a well established company in the Middlewest. College graduate, 28, married. C-1132.

EXPERIENCED ENGINEER, age 40, single, desires investigational work, preferably of electrical and mechanical laboratory research or development type. Ability tested in many ways. Reports on problems requiring originality and resourcefulness, and the supervision of others, most satisfactory. Available after May 15, 1926. Location preferred, Middlewest. B-6273.

ELECTRICAL ENGINEER, technical graduate, ten years' experience with large Eastern manufacturing concern, desires position as instructor in department of electrical engineering. Qualified to teach direct and alternating current machinery, and electrical laboratory. Especially interested in laboratory work. Position must offer possibilities of advancement. Location, West. C-50.

ASSISTANT EXECUTIVE, well balanced experience of thirteen years on cost analysis, industrial processing, commercial statistics, advertising administrative control. Seven years with large company servicing subsidiaries and clients. Public utility experience. Prefers administrative or commercial to strictly technical. Technical graduate, married, 34. Location, New York, New England. Available reasonable notice. B-9122.

ELECTRICAL ENGINEER, age 24, will graduate in June 1926. Interested in sales or distribution of some technical product. C-1306.

CONSTRUCTION ENGINEER, age 38, married, electrical graduate, recent study M. I. T. Allis Chalmers test. Thirteen years' experience electrical manufacture, installation power plant machinery, maintenance, general construction. Desires position steam plant construction. Salary $3600. Available June 1st. A-4018.

TECHNICAL GRADUATE OF BRITISH UNIVERSITY, electrical engineering, age 35, single, over ten years' experience in general electrical and mechanical engineering, including lighting installations, one year illumination tests, about three years mechanical drafting, inspection of finished parts, also two years' experience in patent disclosures and patent drafting. Besides English, speaks and writes two Balkan languages and French. Inventive abilities. Best references. Willing to go anywhere. B-7214.

RADIO COMPASS ENGINEER, technical graduate, desires position with reliable concern in this capacity. Present employed by U. S. Navy Department on position and direction finding by radio. C-723.

ELECTRICAL ENGINEER, B. S. in railway electrical engineering in 1924, 23, single. Two years in general engineering course; two years in central station and substation work in large Midwestern utility engineering department. Location desired, Illinois or foreign. C-1331.

INSTRUCTOR, age 28, single, B. S. and M. S. in E. E., ('23 and '24). Now taking graduate courses in mathematics. Experience; nine months time study and job analysis with an electrical manufacturer, ten months training course in generating and distributing departments of a public utility. Ready to begin about September 6th. C-1034.

ASSISTANT PROFESSORSHIP desired by an electrical engineer seeking promotion above present position. Age 30, married, three years' practical and five years' teaching experience. B. S. and M. S. degrees in electrical engineering. Man of initiative and ability. Desires position in recognized Eastern or Midwestern university. B-3376.

ELECTRICAL ENGINEER, expert switchboard designer, power station layout, relay protection, selection of oil circuit breakers and automatic switching. South West preferred. C-1333.

ELECTRICAL ENGINEER, age 27, experience in research and developing of electrical appliances, desires similar employment. Available on two weeks' notice. Salary $250 a month. B-7270.

ELECTRICAL ENGINEERING GRADUATE, age 31, married, eight years' experience in engineering research, development and teaching electrical theory and laboratory. Graduate study carried on while teaching. Available at once for continuing in similar work. C-3.

SALES ENGINEER, age 34, married, well acquainted with New England markets, desires to represent electrical manufacturer in this territory. Experienced in selling to dealers, jobbers and manufacturers. Technical education. Ten years' Engineering and selling experience. Present connection with internationally known manufacturer. Salary and expenses. Available one month. A-1330.

LICENSED PROFESSIONAL ELECTRICAL ENGINEER, versed also in mechanical, structural steel, concrete and hydraulic work. Power stations, power transmission, industrial plants, etc. Design, construction, operation; practical as well as theoretical (research). Reliable, responsible. B-7337.

RADIO ENGINEER, thoroughly educated, experienced, wants position technical correspondent or development engineer large radio company. Past four years employed as operating engineer, second in charge, in two of New York's broadcasting stations. Designed, constructed, installed third large broadcasting station Second Radio District. Two years magazine, special feature writing experience. Not interested position broadcasting station. Available two weeks' notice. Minimum salary $3000. C-1108.

ELECTRICAL ENGINEER, age 29, married, university graduate, five year course, one year in Commerce and Journalism College. Desires connection with progressive company in commercial capacity or industrial engineering firm. Work has covered estimating, contracting and manufacturing work. Available on reasonable notice. Location, Ohio. B-9865.

MECHANICAL ENGINEER, technical graduate, married, wide experience in design and construction of power plants, fire prevention and protection, and preparation of special reports, extensive acquaintance among city officials. Desires position with contractor or consulting engineer. B-7189.

ELECTRICAL ENGINEER, age 30, married, graduate E. E. M. E. Seven years' varied experience on central and substation estimating, design, construction and installation also safety and research work. Five years in responsible positions with private corporation and public utilities. Good record and references. Desires responsible position requiring ingenuity and good judgment with industrial, engineering or small power company, preferably New York or neighboring state. Available on reasonable notice. B-5505.

ASSISTANT ENGINEER, age 25, single, electrical and mechanical. Eight year course engineering theory and electrical station design. Apprenticed motor and generator building. Installed and repaired gas and crude oil engines, automatic lighting and pumping systems, machinery, etc. Available on seven days' notice. C-1301.

GRADUATE ELECTRICAL ENGINEER, will go anywhere; over twelve years' experience in construction, operation, maintenance of steam generating stations; efficient production of power; meter and installation work. Desires post leading to executive responsibility. Knowledge Spanish. Age 38. Married. $4200 minimum. Available August. C-1372.

ELECTRICAL ENGINEER, COLLEGE GRADUATE. Seventeen years' experience on power station, sub-station, transmission and industrial work as designer, chief draftsman, assistant engineer. Experience with manufacturing companies, Public Utilities and Consulting Engineers. B-7183.

ELECTRICAL construction, maintenance or appraisal engineer, wide experience in construction work including steam turbine installations, largely with electric manufacturing and public utility companies. Competent to make up prices for public utility appraisals. C-1163.

ELECTRICAL ENGINEERING GRADUATE, 29, single, wishes position with engineering or construction firm where the following experience can be used to advantage. Two years' experience on bridges, conveyer equipment, one year test and assembly electrical motors, one one year test and assembly storage batteries. Great adaptability. Hard worker, available immediately. Location, Northern Ohio preferred. B-7908.

GRADUATE ELECTRICAL ENGINEER. Special studies Business Administration—four years varied experience with large manufacturing company and as technical assistant to electrical superintendant large steel company in charge of maintenance and construction. Familiar with all details of the department including estimates, power distribution, tests, and personnel. Excellent references from former employers. C-1297.

ELECTRICAL ENGINEER, age 26, married, technical graduate, four years' experience test supervision with public utility, one year's experience teaching, executive, statistician, organizer. Desires position with progressive organization offering reasonable advancement for conscientious, energetic worker. C-1346.

ELECTRICAL ENGINEER, M. I. T. graduate, two years' active experience in telephone engineering. Desires position with a future with manufacturing company on production, technical, or sales staff. Location, vicinity of New York. Available two weeks. C-1305.

ELECTRICAL and mechanical engineer, university graduate, age 39, married, desires executive or sales position. Twelve years' executive experience, electric railway, light and power. Wide acquaintance among operating officials of all utilities, and manufacturers. Best references. Available May 1st. New York vicinity preferred. C-1235.

ENGINEER, B. S. and E. E. degrees, fifteen years' experience testing, construction, design and supervision of substation and distribution work. Desires connection with manufacturer, public utility, engineer or investment banker employing engineers. Available on one month's notice. B-9551.

ELECTRICAL GRADUATE, age 24, single, desires permanent position engineering work. One year test, one year Caines current field engineering with General Electric Company. Familiar with Utilities of the South. C-1391.

ELECTRICAL ENGINEER, college and technical graduate, age 25 years' broad experience in power plant and substation design, H. T. bus construction, power and light distribution, underground and line transmission, quantity surveys, specification writing, executive correspondence, and office charge desires position with reliable utility company, Atlantic coast preferred. B-3231.

ELECTRICAL ENGINEER, age 26, married, desires position that has good chance for advancement. Fifteen months with General Electric Company as student engineer, two years teaching electrical engineering, three months operating large hydro-electric plant. Available at once. C-54-100.

WATSON, H. KENNETH, Draftsman, Engg. Dept., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
*WEINER, LOUIS, Anaconda Sales Co., 25 Broadway, New York, N. Y.
WEITZMAN, HARRY A., Penn Public Service Corp., Johnstown, Pa.
WESTBROOK, JOSEPH A. ALBERT, Engineer, Street Cable Div., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
WILLIAMS, GEORGE SETH, Vice-President & General Manager, Central Maine Power Co., 317 Water St., Augusta, Me.
WILLIARD, JOHN ANDREW, Electrical Designer, Philadelphia Electric Co., 1035 Chestnut St., Philadelphia, Pa.
*WISSMANN, JOSEPH THEODORE, Receiving Engineer, Radio Corp. of America, Riverhead, N. Y.
WOMER, CLAUDE EMORY, Supt. of Equipment, Shamokin-Mt. Carmel Transit Co., Mt. Carmel, Pa.
WOODS, OSBORNE BAKER, Senior Operator, Newfoundland Power & Paper Co., Deer Lake, Newfoundland.
YOUNT, L. E., Asst. Manager, Western Radio, Inc., 1224 Wall St., Los Angeles, Calif.
ZEPLAIEV, PAUL PETER, Teacher, Elec. Engg. Dept., Polytechnic Institute of Leningrad, Leningrad, Russia.
ZIELINSKI, HEINZ, Draftsman-designer, Kny-Scheerer Corp. of America, 119 7th Ave., New York, N. Y.; res., Sharon, Pa.
ZIMMERMAN, EUGENE FREDERICK, Student Engineer, Southwestern Bell Tel. Co., 512 Planter's Bldg., St. Louis, Mo.

Total 161

*Formerly Enrolled Students.

ASSOCIATES REELECTED MAY 21, 1926

CRANSTON, ROBERT W., Supt. Substations, West Penn Power Co., 14 Wood St., Pittsburgh, Pa.

FLESHIEM, ROBERT STEPHENSON, Asst. Manager, Elec. Dept., Allis-Chalmers Mfg. Co., Milwaukee, Wis.

MAHOOD, EDWIN TERRELL, Valuation Engineer, Southwestern Bell Telephone Co., 569 Boatman's Bank Bldg., St. Louis, Mo.

MEMBER REELECTED MAY 21, 1926

SIMPSON, FRANK, Treasurer, The Collier-Simpson Co., 500 East 102nd St., Cleveland, Ohio.

MEMBERS ELECTED MAY 21, 1926

ALLEN, THOMAS SIMMONS, Engineer, Allis-Chalmers Mfg. Co., 3421 Sycamore St., Milwaukee, Wis.

BARNARD, GLENN HARRISON, Manager, Marine Sales & Philadelphia Dist. Office, Electro-Dynamic Co., Bayonne, N. J.

BECKETT, WILLIAM, Asst. Engineer, Dept. of Development, Georgia Railway & Power Co., Atlanta, Ga.

BURRI, JOSEPH JOHN, Supt. of Distribution, Staten Island Edison Corp., Staten Island, N. Y.

CASTER, JOHN HERBERT, Dist. Engineer, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

FLORY, A. C., Manager, Steam Turbine Dept., Allis-Chalmers Mfg. Co., Milwaukee, Wis.

HARVEY, ARTHUR FREDERIC, Asst. Engineer of Electrification, Central Argentine Railway, Victoria, F. C. C. A., Argentina, S. A.

HOADLEY, HERBERT EUGENE, Distribution Supt., The Ohio Public Service Co., Warren, Ohio.

LEWIS, HAROLD G., Springfield Service Manager, Westinghouse Elec. & Mfg. Co. 395 Liberty St., Springfield, Mass.

McLEAN, JAMES SINCLAIR, Construction Supt., The J. G. White Engineering Corp., 43 Exchange Place, New York, N. Y.

SCHOLZ, CARL E., Chief Engineer, Federal Telegraph Co., Palo Alto, Calif.

SPELLMIRE, WALTER B., Manager, General Electric Co., 1307 Oliver Bldg., Pittsburgh., Pa.

THOMAS, WILLIAM ANDREW, 3rd Radio Engineer, Sonora Phonograph Co., Inc., 279 Broadway, New York; res., Brooklyn, N. Y.

THOMSON, OSCAR ROLAND, Asst. Supt., C. O. S., Hydro-Electric Power Commission of Ontario, Belleville, Ont., Can.

TRETJAK, GREGORY TIMOTHY, Teacher, Elec. Engg. Dept., Electrotechnical Institute, Pessotchnaya 5, log. 6, Leningrad, Russia.

UPP, JOHN W., Jr., Electrical Engineer, Ohio Brass Co., Mansfield, Ohio.

WILLISON, JOHN WRIGHT, Supt., Yorkshire Electric Pr. Co., 36 Park Place, Leeds, Yorkshire, Eng.

FELLOW ELECTED MAY 21, 1926

KLOSS, MAX, Prof. of Elec. Engg., Technische Hochschule, Charlottenburg; for mail, Berlin-Nikolassee, Germany.

TRANSFERRED TO GRADE OF FELLOW MAY 21, 1926

DWIGHT, HERBERT BRISTOL, Professor, Massachusetts Institute of Technology, Cambridge, Mass.

HEINZE, CARL A., Electrical Engineer in charge of Distribution, Department ofWater & Power, City of Los Angeles, Los Angeles, Calif.

OEHLER, ALFRED G., Editor — *Railway Electrical Engineer*, Electrical Editor — *Railway Age*, New York, N. Y.

TRANSFERRED TO GRADE OF MEMBER MAY 21, 1926

ANDERSON, EDWARD T., Electrical Engineer, Board of Water & Electric Light Commissioners, Lansing, Mich.

BACKUS, CYRUS D., Principal Examiner, U. S. Patent Office, Washington, D. C.

BOHNERT, ARTHUR M., District Engineer, Ohio Brass Co., San Francisco, Calif.

BOLLINGER, HOWARD M., Supervisor of Plant Methods, Chesapeake & Potomac Telephone Co., Washington, D. C.

BROCKWAY, R. M., Engineer, Switchboard Dept., General Electric Co., Schenectady, N. Y.

CARPE, ALLEN, Engineer, Dept. of Development & Research, American Telephone & Telegraph Co., New York, N. Y.

CLAPP, ROBERT H., Telegraph Engineer, American Telephone & Telegraph Co., New York, N. Y.

COLBURN, WELLEN H., Electrical Engineer, Station Engineering Dept., Edison Electric Illuminating Co. of Boston, Boston, Mass.

FINCH, WILLIAM G. H., Radio Editor and Engineer, International News Service, New York, N. Y.

GIBSON, E. S., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.

JACKSON, DUGALD C., Jr., Asst. Professor of Electrical Engineering, Trinity College, Durham, N. C.

RAMIREZ, JAVIER P., Consulting Engineer, Professor Escuela de Ingenieros Mecanicos Electricistas, Mexico City, Mex.

RORTY, M. C., President, International Telephone Securities Corp. — Vice-President, International Tel. & Tel. Corp., New York, N. Y.

SAATHOFF, GEORGE W., Chief Construction Engineer, Henry L. Doherty & Co., New York, N. Y.

SPORN, PHILIP, Assistant to Electrical Engineer, American Gas & Electric Co., New York, N. Y.

SPRACKLEN, EMERY E., Electrical Engineer in charge of Design, Ohio Public Service Co., Massillon, Ohio.

TAYLOR, NEWTON S., Manager, Switchboard Section Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

WHIPPLE, CLYDE C., Asst. Professor of Electrical Engineering, Polytechnic Iustitute, Brooklyn, N. Y.

RECOMMENDED FOR TRANSFER

The Board of Examiners, has recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

FONDILLER, WILLIAM, in charge, General Development Laboratory, Bell Telephone Laboratories, New York, N. Y.

HUBLEY, GEORGE W., Consulting and Advisory Engineer, Louisville, Ky.

STRENG, LEWIS S., Vice-President in charge of Operation, Louisville Gas & Electric Co., Louisville, Ky.

To Grade of Member

AMES, NORMAN B., Assistant Professor of Electrical Engineering, George Washington University, Washington, D. C.

BAILEY, RAYMOND, Chief Electrical Designer, Philadelphia Electric Co., Philadelphia, Pa.

CELIS, ATILIO, Manager-Engineer, San Juan Office of International General Electric Co., Inc., San Juan, P. R.

CHADWICK, RALPH H., Section Head, Transformer Engineering Dept., General Electric Co., Fort Wayne, Ind.

CLEARY, LEO H., Electrical Engineer, Standard Engineering Co., Washington, D. C.

EDISON, OSKAR E., Associate Professor of Electrical Engineering, University of Nebraska, Lincoln, Neb.

FEDER, JOSEPH B., Electrical Engineer, Chas. Cory & Son, Inc., New York, N. Y.

GARRISON, DWIGHT, Supt., Telephone Dept., Atlantic Refining Co., Philadelphia, Pa.

GAYLORD, JOHN C., Electrical Engineer' Southern California Edison Co., Los Angeles, Calif.

GORDON, LESLIE B., Chief Electrical and Power Engineer, Kelly-Springfield Tire Co., Cumberland, Md.

HALPENNY, R. H., Electrical Engineer, Southern Sierras Power Co., Riverside, Calif.

HAMILTON, JAMES T., Supt. of Equipment, New York, Westchester & Boston R. R., New York & Stamford Ry. Co., Westchester Street Ry. Co., New York, N. Y.

HECHT, J. BERNARD, Outside Plant Engineer, Tri-State Tel. & Tel. Co., St. Paul, Minn.

HESTER, EDGAR A., Transmission Planning Engineer, Duquesne Light Co., Pittsburgh, Pa.

HOWK, CLARENCE L., Telephone Engineer, International Standards Electric Corp., New York, N. Y.

KARCHER, E. KENNETH, Chief Electrical Engineer, Utica Gas & Electric Co., Utica, N. Y.

KENNEDY, S. M., Vice President, Southern California Edison Company, Los Angeles, Cal.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before June 30, 1926.

Alberti, J. N., General Electric Co., Schenectady, N. Y.

Allen, J. G., Duquesne Light Co., Pittsburgh, Pa.

Ames, A. W., Lighting Dept., City of Seattle, Seattle, Wash.

Auten, L. D., Cleveland Railway Co., Cleveland, Ohio

Ballantine, R. A., Penn Electrical Engineering Co., Scranton, Pa.

Ballard, W. C., Jr., Cornell University, Ithaca, N. Y.

Banan, H. F., Westinghouse Elec. & Mfg. Co., Boston, Mass. (Applicant for re-election.)

Barse, J. H., McKinney Steel Co., Cleveland, Ohio

Bartholomew, F. J., Bartholomew, Montgomery & Co., Ltd., Vancouver, B. C.

Barton, S., Federal Telegraph Co., Clearwater, Calif.

Bayles, C. G., Black & Veatch, Kansas City, Mo.

Becker, H., Jr., Interborough Rapid Transit Co., New York, N. Y.

Beckett, R. V., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Bennett, J. W., Eastern N. J. Power Co., Allenhurst, N. J.

Bergholtz, H., General Electric Co., Schenectady, N. Y.

Binder, G. A., Ohio Brass Co., Chicago, Ill.

Blake, F. J., Public Service Co. of Colorado, Denver, Colo.

Bodge, H. H., (Member), Fall River Electric Light Co., Fall River, Mass.

Borgeson, S. E., Western Electric Co., Inc., Hawthorne Sta., Chicago, Ill.

Bornholz, F. J., (Member), Shanghai Municipal Council, Shanghai, China. (For mail, San Francisco, Calif.)

Bothwell, F. A., General Electric Co., Schenectady, N. Y.

Boyere, E. E., (Member), Electrical Specialist, Erie, Pa.

Brackett, N. W., Puget Sound Power & Light Co., Seattle, Wash.

Braithwaite, W. S., Edison Elec. Illuminating Co., Boston, Mass. (Applicant for re-election.)

Brennon, L. A., General Electric Co., Erie, Pa.

Bristow, T. N., H. B. Squires Co., Seattle, Wash.

Brown, J. F., Tri-State College, Angola, Ind.

Brown, L., City of Seattle, Lighting Dept., Seattle, Wash.

Buchanan, E. C., The Pacific Tel. & Tel. Co., Portland, Ore. (Applicant for re-election.)
Burckett, D. M., Great Northern Railway, Seattle, Wash.
Burrow, P., Supt. of Power Plant, Dryden, Wash.
Bustillo, F. E., Mexican Light & Power Co., Mexico D. F., Mex.
Butler, W. C., The Pacific Tel. & Tel. Co., Seattle, Wash.
Butow, F. W. C., Pacific Coast Steel Co., S. San Francisco, Calif.
Butt, F. H., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Campbell, T. L., Toronto Hydro-Electric System, Toronto, Ont., Can.
Carrick, J. F. C., General Electric Co., Niagara Falls, N. Y.
Carter, T. B., Cumberland Tel. & Tel. Co., Louisville, Ky. (Applicant for re-election.)
Chambers, H. D., Puget Sound Power & Light Co., Seattle, Wash.
Christianson, E. C., Puget Sound Power & Light Co., Tacoma, Wash.
Cirella, L. E., Simplex Wire & Cable Co., Cambridge, Mass.
Cooper, R. F., Miller Rubber Co., Akron, Ohio
Crago, P. H., Union Switch & Signal Co., Swissvale, Pa.
Craven, F. E., Bell Telephone Co. of Pa., Philadelphia, Pa.
Crawford, J. M., General Electric Co., Schenectady, N. Y.
Crock, I. Z., New England Tel. & Tel. Co., Boston, Mass.
Crump, L. W., Puget Sound Power & Light Co., Tacoma, Wash.
Cunningham, K. G., Ohio Bell Telephone Co., Cleveland, Ohio
Curtis, G. V., General Electric Co., Schenectady, N. Y.
Cuthbert, J. T., Duquesne Light Co., Pittsburgh, Pa.
Davis, W., Toronto Hydro-Electric System, Toronto, Ont., Can.
Day, W. P., General Electric Co., Schenectady, N. Y.
de Lima, C. A., Westinghouse Elec. International Co., Mexico, D. F.
Deneen, R. J., Ohio Brass Co., Chicago, Ill.
de Vries, B. D., Duquesne Light Co., Pittsburgh, Pa.
Dibblee, J., (Member), Hydro-Elec. Pr. Commission of Ontario, Toronto, Ont., Can.
Diehl, W. A., National Malleable & Steel Castings Co., Cleveland, Ohio
Doane, P., New York Edison Co., New York, N. Y.
Dowe, G. P., The Canadian Crocker-Wheeler Co., St. Catharines, Ont., Can.
Drake, R. A., U. S. S. Arizona, San Francisco, Calif.
Duevel, C. O., Jr., Consumers Central Heating Co., Tacoma, Wash.
Duffy, L., Puget Sound Power & Light Co., Seattle, Wash.
Eveland, G. H., Feather River Power Co., San Francisco, Calif.
Fagan, H. J., 1555 Walton Ave., Bronx, New York, N. Y.
Falk, V. E., Stone & Webster, Inc., Boston, Mass.
Falor, H. L., Northern Ohio Power & Light Co., Akron, Ohio
Flory, C. L., Radio Corp. of America, Tuckerton, N. J.
Fontaine, J., North Carolina State College, Raleigh, N. C.
Forsyth, J. W., Engineer, City of Philadelphia, Philadelphia, Pa.
Free, J. E., General Electric Co., Philadelphia, Pa.
Fuhs, R. H., Indianapolis Light & Heat Co., Indianapolis, Ind.
Gale, Arthur P., Wisconsin Power & Light Co., Madison, Wis.
Gantenbein, E. F., Puget Sound Power & Light Co., Olympia, Wash.
Garner, F. E., Daven Radio Corp., Newark, N. J.
Ghen, M. W., Duquesne Light Co., Pittsburgh, Pa.
Giangrande, D. M., The New York Edison Co., New York, N. Y.
Gibney, E. L., Lighting Dept., City of Seattle, Seattle, Wash.
Gibson, F. C., Edison Storage Battery Co., Seattle, Wash.
Gillis, M. D., General Electric Co., Erie, Pa.
Gilson, W. J., Canadian & General Finance Co., Toronto, Ont., Can.
Goyne, T. S., Goyne Steam Pump Co., Ashland, Pa.
Graul, E. A., Duquesne Light Co., Pittsburgh, Pa.
Graves, J. M., (Member), Duquesne Light Co., Pittsburgh, Pa.
Hall, I. E., Roller-Smith Co., Bethlehem, Pa.
Hansen, T. A., Puget Sound Power & Light Co., Seattle, Wash.
Harkins, P. S., Bell Telephone Co. of Pa., Philadelphia, Pa.
Harrell, F. E., Reliance Electric & Engineering Co., Cleveland, Ohio
Hartle, W. G., General Electric Co., Schenectady, N. Y.
Haskens, A. J., Union Switch & Signal Co., Swissvale, Pa.
Helander, W. N., Puget Sound Power & Light Co., Olympia, Wash.
Hicks, L. V., (Member), Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Hillock, J. F., Duquesne Light Co., Pittsburgh, Pa.
Hite, J. W., Reliance Electric & Engineering Co., Cleveland, Ohio
Hoehn, E. H., Union Electric Light & Power Co., St. Louis, Mo.
Hults, The Ohio Public Service Co., Warren, Ohio
Hurlburt W. O., Gas & Electric Service Co., Chico, Calif.
Hyams, L. B., Gothem Electric & Supply Co., New York, N. Y.
Hyle, L. C., Emaus Telephone Co., Emaus, Pa.
Ishikawa, K., International General Electric Co., Schenectady, N. Y.
Jayne, J. K., Autocar Co., Brooklyn, N. Y.
Johnson, E. L., H. B. Squires Co., Seattle, Wash.
Johnson, R. H., Puget Sound Power & Light Co., Bremerton, Wash.
Johnson, R. R., Duquesne Light Co., Pittsburgh, Pa.
Keefer, J., Pacific Coast Steel Co., S. San Francisco, Calif.
Kellers, C. F., General Electric Co., Schenectady, N. Y.
Kepple, K. A., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Kilbury, W. A., Cleveland Elec. Illuminating Co., Cleveland, Ohio
Kincaid, M. B., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Klingenberg, F., Thomas E. Murray, Inc., New York, N. Y.
Knaus, F., Lighting Dept., City of Seattle, Seattle, Wash.
Krauskop, V. O., American Electric Power Co., Philadelphia, Pa.
Laube, L. F., General Electric Co., Schenectady, N. Y.
Lavo, K. E., General Electric Co., Schenectady, N. Y.
Lindstrom, C. T., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Linton, S., Stone & Webster, Inc., Boston, Mass.
Loughridge, C. H., (Member), Consulting Engineer, Cleveland, Ohio
Manahan, W. T., Consolidated Gas, Elec. Lt. & Pr. Co. of Baltimore, Baltimore, Md.
Marsten, J., Freed-Eisemann Radio Corp., Brooklyn, N. Y.
Marthakis, G. S., General Electric Co., Schenectady, N. Y.
Martyn, C. A., Puget Sound Power & Light Co., Tacoma, Wash.
Mason, H. R., Ohio State University, Columbus, Ohio
McBride, B. V., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
McCuaig, D. A., Stone & Webster, Inc., Boston, Mass.
McNichall, J. F., Gould Storage Battery Co., Depew, N. Y.
Means, L. H., General Electric Co., Schenectady, N. Y.
Merritt, D. F., Famous Players Lasky Co., Hollywood, Calif.
Merry, F. S., Toronto Hydro-Electric System, Toronto, Ont., Can.

FARLEY OSGOOD, 1924-25.

*Deceased.

LOCAL HONORARY SECRETARIES

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina, S. A.
Carroll M. Mauseau, Caixa Postal No. 571, Rio de Janeiro, Brazil, S. A.
Charles le Maistre, 28 Victoria St., London, S. W. 1, England.
A. S. Garfield, 45 Bd. Beausejour, Paris 16 E, France.
F. W. Willis, Tata Power Companies, Bombay House, Bombay, India.
Guido Semenza, 39 Via Monte Napoleone, Milan, Italy.
P. H. Powell, Canterbury College, Christchurch, New Zealand.
Axel F. Enstrom, 24a Grefturegatan, Stockholm, Sweden.
W. Elsdon-Dew, P. O. Box 4563, Johannesburg, Transvaal, Africa.

A. I. E. E Committees

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

M. I. Pupin, Chairman, 1 W. 72nd St., New York
Farley Osgood Vice-Chairman
H. P. Charlesworth, G. A. Hamilton, G. L. Knight, H. W. Eales, W. K. Vanderpoel.

FINANCE COMMITTEE

G. L. Knight, Chairman, Pearl & Willoughby Sts., Brooklyn, N. Y
L. F. Morehouse, W. K. Vanderpoel

MEETINGS AND PAPERS COMMITTEE

E. B. Meyer, Chairman, 80 Park Place, Newark, N. J.
E. H. Hubert, Secretary, 33 W. 39th St., New York
A. W. Berresford, H. W. Eales, C. E. Skinner, E. E. F. Creighton, J. E. Macdonald, Harold B. Smith, L. W. W. Morrow
Chairman of Committee on Coordination of Institute Activities, ex-officio.
Chairmen of technical committees, *ex-officio*.

PUBLICATION COMMITTEE

L. F. Morehouse, Chairman, 195 Broadway, New York
F. L. Hutchinson, Donald McNicol, J. H. Morecroft, E. B. Meyer.

COMMITTEE ON COORDINATION OF INSTITUTE ACTIVITIES

Farley Osgood, Chairman, 31 Nassau Street, New York, N. Y.
F. L. Hutchinson, E. B. Meyer, W. I. Slichter, G. L. Knight, L. F. Morehouse, Harold B. Smith.

BOARD OF EXAMINERS

Erich Hausmann, Chairman, Polytechnic Institute of Brooklyn, Brooklyn, N. Y.
H. W. Drake, Harold Goodwin, Jr., W. M. McConahey, E. H. Everit, F. V. Magalhaes, N. L. Pollard, F. M. Farmer, W. I. Slichter.

SECTIONS COMMITTEE

Harold B. Smith, Chairman, Worcester Polytechnic Institute, Worcester, Mass.
H. H. Henline, W. B. Kouwenhoven, Herbert S. Sands, C. E. Magnusson,
Chairmen of Sections, *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. E. Magnusson, Chairman, University of Washington, Seattle, Wash.
C. Francis Harding, Charles F. Scott, W. H. Timbie, Harold B. Smith,
Student Branch Counselors, ex-officio.

MEMBERSHIP COMMITTEE

J. L. Woodress, Chairman, 1806 Pine Street, St. Louis, Mo.
R. B. Bonney, J. M. Bryant, E. E. Dorting, L. S. O'Roark, C. K. Chapin, R. B. Mateer, George E. Quinan, H. C. Don Carlos, S. H. Mortensen, A. E. Soderholm,
Chairmen of Section membership committees, *ex-officio*.

HEADQUARTERS COMMITTEE

H. A. Kidder, Chairman, 600 W. 59th Street, New York
F. L. Hutchinson, G. L. Knight.

LAW COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York
H. H. Barnes, Jr., L. F. Morehouse, Charles A. Terry, R. F. Schuchardt,

PUBLIC POLICY COMMITTEE

Gano Dunn, Chairman, 43 Exchange Place, New York
A. W. Berresford, F. B. Jewett, William McClellan, H. W. Buck, John W. Lieb, Harris J. Ryan.

STANDARDS COMMITTEE

Executive Committee

H. S. Osborne, Chairman, 195 Broadway, New York
H. E. Farrer, Secretary, 33 W. 39th Street, New York
W. A. Del Mar, A. M. MacCutcheon, C. H. Sharp, H. B. Gear, J. Franklin Meyer, C. E. Skinner, C. R. Harte, F. D. Newbury, W. I. Slichter, H. M. Hobart, Harold Pender, R. H. Tapscott, H. A. Kidder, F. L. Rhodes, H. R. Woodrow, L. T. Robinson,

Ex-officio

Chairmen of Working Committees
Chairmen of A. I. E. E. delegations on other standardizing bodies.

EDISON MEDAL COMMITTEE

Appointed by the President for term of five years.

B. A. Behrend, (Terms expire July 31, 1926) John H. Finney, C. S. Ruffner.
Gano Dunn, Chairman, (Terms expire July 31, 1927) F. A. Scheffler, W. R. Whitney.
C. C. Chesney, (Terms expire July 31, 1928) Robert A. Millikan, M. I. Pupin.
N. A. Carle, (Terms expire July 31, 1929) W. C. L. Eglin, John W. Lieb.
George Gibbs, (Terms expire July 31, 1930) Samuel Insull, Ralph D. Mershon.

Elected by the Board of Directors from its own membership for term of two years.

L. F. Morehouse, (Terms expire July 31, 1926) Harris J. Ryan, Harold B. Smith.
W. P. Dobson, (Terms expire July 31, 1927) Farley Osgood, A. G. Pierce.

Ex-Officio

M. I. Pupin, President, George A. Hamilton, National Treasurer, F. L. Hutchinson, National Secretary

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

John W. Lieb, Chairman, 124 E. 15th Street, New York
C. A. Adams, G. Faccioli, L. F. Morehouse, A. H. Babcock, R. D. Mershon, C. E. Skinner.

COMMITTEE ON AWARD OF INSTITUTE PRIZES

E. B. Meyer, Chairman, 80 Park Place, Newark, N. J.
L. F. Morehouse, Percy H. Thomas.

COMMITTEE ON AWARD OF COLUMBIA UNIVERSITY SCHOLARSHIPS

W. I. Slichter, Chairman, Columbia University, New York
Francis Blossom, H. C. Carpenter.

COMMITTEE ON SAFETY CODES

Paul Spencer, Chairman, 1401 Arch St., Philadelphia, Pa.
F. A. Barron, H. B. Gear, R. W. E. Moore, Philander Betts, P. J. Howe, Farley Osgood, W. J. Canada, L. C. Ilsley, George Quinan, R. N. Conwell, M. G. Lloyd, Joseph Sachs, J. V. B. Duer, Ernest Lunn, H. R. Sargent, J. C. Forsyth, Wills Maclachlan, W. H. Sawyer, R. C. Fryer, J. C. Martin, M. L. Sindeband, D. H. Gage, J. E. Moore, H. S. Warren.

SPECIAL COMMITTEES

LICENSING OF ENGINEERS

Francis Blossom, Chairman, Sanderson & Porter, 52 William Street, New York
H. W. Buck, Gano Dunn, E. W. Rice, Jr., L. E. Imlay,

TECHNICAL ACTIVITIES

A. G. Pierce, Chairman, 1239 Guardian Building, Cleveland, Ohio
H. P. Charlesworth, H. M. Hobart, J. B. Whitehead, H. A. Kidder,

TECHNICAL COMMITTEES

COMMUNICATION

H. P. Charlesworth, Chairman, 195 Broadway, New York

F. L. Baer, O. B. Blackwell, L. W. Chubb, Charles E. Davies, H. W. Drake, Major P. W. Evans, R. D. Evans, E. H. Everit, L. F. Fuller, D. H. Gage, S. P. Grace, P. J. Howe, F. H. Kroger, N. M. Lash, Ray H. Manson, R. D. Parker, H. S. Phelps, Lieut. Comm. B. B. Ralston, F. A. Raymond, Chester W. Rice, J. K. Roosevelt, H. A. Shepard, John F. Skirrow, E. B. Tuttle, E. A Wolff, C. A. Wright.

EDUCATION

Harold Pender, Chairman, University of Pennsylvania, Philadelphia, Pa.

C. A. Adams, Bion J. Arnold, Edward Bennett, Gano Dunn, W. C. L. Eglin, C. E. Eveleth, D. C. Jackson, F. B. Jewett, Farley Osgood, Harold B. Smith, R. W. Sorensen, J. B. Whitehead, W. R. Whitney, W. E. Wickenden.

ELECTRICAL MACHINERY

H. M. Hobart, Chairman, General Electric Co., Schenectady, N. Y.
J. C. Parker, Vice-Chairman, Brooklyn, N. Y.
E. B. Paxton, Secretary, General Electric Co., Schenectady, N. Y.

C. A. Adams, H. C. Albrecht, B. F. Bailey, B. L. Barns, B. A. Behrend, A. C. Bunker, James Burke, Walter M. Dann, L. L. Elden, G. Faccioli, W. J. Foster, Harold Goodwin, Jr., J. I. Hull, V. Karapetoff, A. H. Kehoe, A. E. Kennelly, P. M. Lincoln, A. M. MacCutcheon, F. D. Newbury, N. L. Pollard, R. F. Schuchardt, C. E. Skinner, A. Still, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

G. W. Vinal, Chairman, Bureau of Standards, Washington, D. C.

Lawrence Addicks, Arthur N. Anderson, T. C. Atchison, Farley G. Clark, Safford K. Colby, F. A. J. Fitzgerald, W. F. Hendry, Walter E. Holland, F. A. Lidbury, Wm. A. Moore, Carl G. Schluederberg, Magnus Unger, J. B. Whitehead, J. L. Woodbridge, J. L. McK. Yardley.

ELECTROPHYSICS

J. H. Morecroft, Chairman, Columbia University, New York

V. Bush, R. E. Doherty, Herbert Bristol Dwight, Charles Fortescue, V. Karapetoff, A. E. Kennelly, W. B. Kouwenhoven, R. A. Millikan, F. W. Peek, Jr., Harold Pender, Chester W. Rice, J. Slepian, Harold B. Smith, J. B. Whitehead.

INSTRUMENTS AND MEASUREMENTS

A. E. Knowlton, Chairman, Dunham Laboratory, Yale University, New Haven, Conn.
F. V. Magalhaes, Vice-Chairman
H. B. Brooks, Secretary

O. J. Bliss, Perry A. Borden, W. M. Bradshaw, J. R. Craighead, W. A. Del Mar, E. D. Doyle, W. M. Goodwin, Jr., C. M. Jansky, Jr., W. B Kouwenhoven, P. M. Lincoln, W. M. McConahey, W. J. Mowbray, H. A. Perkins, L. T. Robinson, Bryon W. St. Clair, G. A. Sawin, I. B. Smith, Roy Wilkins.

APPLICATIONS TO IRON AND STEEL PRODUCTION

F. B. Crosby, Chairman, Morgan Construction Co., 15 Belmont St., Worcester, Mass.

A. C. Cummins, W. C. Kennedy, A. G. Pierce, A. G. Place, F. O. Schnure, G. E. Stoltz, J. D. Wright.

PRODUCTION AND APPLICATION OF LIGHT

Preston S. Millar, Chairman, Electrical Testing Laboratories, 80th St. & East End Ave., New York

W. T. Blackwell, J. M. Bryant, W. T. Dempsey, H. W. Eales, F. M. Peiker, F. F. Fowle, G. C. Hall, H. H. Higbie, A. S. McAllister, G. S. Merrill, F. H. Murphy, Charles F. Scott, B. E. Shackelford, C. J. Stahl, G. H. Stickney.

APPLICATIONS TO MARINE WORK

L. C. Brooks, Chairman, Common Street, Groton, Mass.
H. F. Harvey, Jr., Vice-Chairman
J. S. Jones, Secretary

R. A. Beekman, J. P. Clinton, C. S. Gillette, William Hetherington, Jr., H. L. Hibbard, Edward C. Jones, A. Kennedy, Jr., M. A. Libbey, E. B. Merriam, I. H. Osborne, G. A. Pierce, H. M. Southgate, W. E. Thau, C. P. Turner, A. E. Waller, J. L. Wilson, R. L. Witham.

APPLICATIONS TO MINING WORK

F. L. Stone, Chairman, General Electric Co., Schenectady, N. Y.

W. C. Adams, M. C. Benedict, Graham Bright, H. W. Eales, L. C. Ilsley, G. M. Kennedy, R. L. Kingsland, A. B. Kiser, Carl Lee, W. H. Lesser, John A. Malady, Charles H. Matthews, D. C. McKeehan, W. F. Schwedes, W. A. Thomas, C. D. Woodward.

GENERAL POWER APPLICATIONS

A. M. MacCutcheon, Chairman, Reliance Electric Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio

P. H. Adams, D. H. Braymer, H. E. Bussey, R. P. Chamberlain, C. W. Drake, E. W. Henderson, H. D. James, P. C. Jones, G. A. Kositzky, A. C. Lanier, W. S. Maddocks, N. L. Mortensen, H. W. Rogers, H. L. Smith, W. H. Timbie, W. K. Vanderpoel, A. E. Waller, W. C. Yates.

POWER GENERATION

Vern E. Alden, Chairman, Consolidated Gas & Electric Company, Baltimore, Md.

H. A. Barre, E. T. Brandon, H. W. Eales, N. E. Funk, C. F. Hirshfeld, Francis Hodgkinson, P. Junkersfeld, H. A. Kidder, J. T. Lawson, W. H. Lawrence, James Lyman, W. E. Mitchell, I. E. Moultrop, J. C. Parker, M. M. Samuels, F. A. Scheffler, R. F. Schuchardt, A. R. Smith, Nicholas Stahl, W. M. White.

POWER TRANSMISSION AND DISTRIBUTION

P. H. Thomas, Chairman, 120 Broadway, New York
P. H. Chase, Vice-Chairman, Philadelphia, Pa.
R. N. Conwell, Vice-Chairman, Newark, N. J.
F. M. Farmer, Secretary, 80th St. & East End Ave., New York

C. G. Adsit, R. W. Atkinson, A. O. Austin, F. G. Baum, John A. Brundige, V. Bush, George F. Chellis, Wallace S. Clark, Edith Clarke, W. H. Cole, M. T. Crawford, John C. Damon, W. A. Del Mar, Herbert H. Dewey, L. L. Elden, R. D. Evans, C. L. Fortescue, C. D. Gray, W. A. Hillebrand, J. P. Jollyman, A. H. Kehoe, C. H. Kraft, A. H. Lawton, W. E. Meyer, W. E. Mitchell, Clifford R. Oliver, John C. Parker, F. W. Peek, Jr., G. G. Post, D. W. Roper, C. E. Schwenger, A. E. Silver, M. L. Sindeband, H. C. Sutton, Philip Torchio, Theodore Varney, H. S. Warren, R. J. C. Wood.

PROTECTIVE DEVICES

E. C. Stone, Chairman, Duquesne Light Co., 435 Sixth Ave., Pittsburgh, Pa.
F. L. Hunt, Vice-Chairman, Greenfield, Mass.

W. S. Edsall, H. Halperin, F. C. Hanker, S. E. M. Henderson, R. A. Hentz, E. A. Hester, George S. Humphrey, J. Allen Johnson, M. G. Lloyd, H. C. Louis, A. A. Meyer, W. H. Millan, J. M. Oliver, N. L. Pollard, E. J. Rutan, E. R. Stauffacher, H. R. Summerhayes.

RESEARCH

John B. Whitehead, Chairman, Johns Hopkins University, Baltimore, Md.

Edward Bennett, V. Bush, E. H. Colpitts, E. E. F. Creighton, W. F. Davidson, W. A. Del Mar, B. Gherardi, V. Karapetoff, A. E. Kennelly, M. G. Lloyd, F. W. Peek, Jr., Harold Pender, E. W. Rice, Jr., D. W. Roper, C. H. Sharp, C. E. Skinner, Harold B. Smith, R. W. Sorensen.

TRANSPORTATION

Cary T. Hutchinson, Chairman, 52 William Street, New York

J. V. B. Duer, George Gibbs, W. K. Howe, D. C. Jackson, John Murphy, W. S. Murray, W. B. Potter, N. W. Storer, Richard H. Wheeler

---

A. I. E. E. Representatives

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE COUNCIL

A. E. Kennelly, John B. Taylor.

AMERICAN BUREAU OF WELDING

H. M. Hobart.

AMERICAN COMMITTEE ON ELECTROLYSIS

B. J. Arnold, N. A. Carle, F. N. Waterman.

AMERICAN ENGINEERING COUNCIL ASSEMBLY

Comfort A. Adams, C. G. Adsit, *A. W. Berresford, H. W. Eales, *John H. Finney, M. M. Fowler, H. M. Hobart, F. L. Hutchinson, *D. C. Jackson, William McClellan, L. F. Morehouse, *Farley Osgood, M. I. Pupin, *E. W. Rice, Jr., *Charles F. Scott, *C. E. Skinner, Calvert Townley.

*Members of Administrative Board

AMERICAN ENGINEERING STANDARDS COMMITTEE

H. M. Hobart, H. S. Osborne, C. E. Skinner, L. T. Robinson (Alternate)

AMERICAN MARINE STANDARDS COMMITTEE

John F. Clinton, G. A. Pierce (Alternate)

AMERICAN YEAR BOOK, ADVISORY BOARD

Edward Caldwell

APPARATUS MAKERS AND USERS, COMMITTEE OF. NATIONAL RESEARCH COUNCIL

C. E. Skinner

BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY

H. H. Barnes, Jr. Bancroft Gherardi, G. L. Knight

CHARLES A. COFFIN FELLOWSHIP AND RESEARCH FUND COMMITTEE

M. I. Pupin

ELIMINATION OF FATIGUE, COMMITTEE ON, SOCIETY OF INDUSTRIAL ENGINEERS

C. Francis Harding

ENGINEERING FOUNDATION BOARD

Gano Dunn, L. B. Stillwell.

JOHN FRITZ MEDAL BOARD OF AWARD

Gano Dunn, Frank B. Jewett, M. I. Pupin
Farley Osgood.

JOINT COMMITTEE ON WELDED RAIL JOINTS

D. D. Ewing, A. P. Way.

JOINT CONFERENCE COMMITTEE OF FOUNDER SOCIETIES

The Presidents and Secretaries, *ex-officio*.

LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle,
E. B. Craft, W. I. Slichter.

NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

Paul Spencer.

NATIONAL FIRE WASTE COUNCIL

John H. Finney, Paul Spencer.

NATIONAL MUSEUM OF ENGINEERING AND INDUSTRY

Board of Trustees
Gano Dunn F. B. Jewett

NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

John B. Whitehead A. E. Kennelly, E W. Rice, Jr.

LIST OF SECTIONS

Name	Chairman	Secretary
Akron	Ralph Higgins	John Grotzinger, 64 Marguerite Ave., Cuyahoga Falls, Ohio
Atlanta	W. E. Gathright	W. F. Oliver, Box 2211, Atlanta, Ga.
Baltimore	W. B. Kouwenhoven	R. T. Greer, Madison St. Building, Baltimore, Md.
Boston	J. W. Kidder	W. H. Colburn, 39 Boylston Street, Boston, Mass.
Chicago	Carl Lee	B. E. Ward, Room 1679, 230 S. Clark St., Chicago, Ill.
Cincinnati	H. C. Blackwell	E. S. Fields, Union Gas & Electric Co., Cincinnati, Ohio
Cleveland	Chester L. Dows	J. F. Schnable, 3503 Mapledale Ave., Cleveland, Ohio
Columbus	R. J. B. Feather	W. T. Schumaker, 25½ North High St., Columbus, Ohio
Connecticut	A. A. Packard	A. E. Knowlton, Dunham Laboratory, Yale University, New Haven, Conn.
Denver	V. L. Board	R. B. Bonney, Telephone Building, P. O. Box 960, Denver, Colo.
Detroit-Ann Arbor	G. B. McCabe	Harold Cole, Detroit Edison Co., 2000 Second Ave., Detroit, Mich.
Erie	H. J. Hansen	L. H. Curtis, General Electric Co., Erie, Pa.
Fort Wayne	E. L. Gaines	D. W. Merchant, General Electric Co., Fort Wayne, Ind.
Indianapolis-Lafayette	H. M. Anthony	J. B. Bailey, 48 Monument Circle, Indianapolis, Ind.
Ithaca	J. G. Pertsch, Jr.	Geo. F. Bason, Cornell University, Ithaca, N. Y.
Kansas City	R. L. Baldwin	S. M. DeCamp, 510 Dwight Bldg., Kansas City, Mo.
Lehigh Valley	W H. Lesser	G. W. Brooks, Pennsylvania Power & Light Co., Allentown, Pa.
Los Angeles	R. A. Hopkins	R. E. Cunningham, 1725 Camden Ave., So. Pasadena, Calif.
Lynn	E. D. Dickinson	F. S. Jones, General Electric Co., Lynn, Mass.
Madison	L. E. A. Kelso	Leo J. Peters, University of Wisconsin, Madison, Wis.
Mexico	E. F. Lopez	H. Larralde, Isabel La Catolica, 33 Mexico, D. F., Mexico
Milwaukee	H. R. Huntley	L. F. Seybold, 446 Public Service Building, Milwaukee, Wis.
Minnesota	A. G. Dewars	J. E. Sumpter, 919-23 Security Building, Minneapolis, Minn.
Nebraska	O. J. Ferguson	C. W. Minard, 509 Electric Building, Omaha, Neb.
New York	H. A. Kidder	H. V. Bozell, Bonbright & Co., 25 Nassau St., New York, N. Y.
Niagara Frontier	J. Allen Johnson	A. W. Underhill, Jr., 606 Lafayette Building, Buffalo, N. Y.
Oklahoma	E. R. Page	C. C. Stewart, Oklahoma Gas & Elec. Co., Norman, Okla.
Panama	L. W. Parsons	I. F. McIlhenny, Box 413, Balboa Heights, C. Z.
Philadelphia	Nathan Shute	R. H. Silbert, 2301 Market St., Philadelphia, Pa.
Pittsburgh	G. S. Humphrey	W. C. Goodwin, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Pittsfield	E. D. Eby	C. H. Kline, General Electric Co., Pittsfield, Mass.
Portland, Ore.	L. W. Ross	J. C. Henkle, Hawthorne Building, Portland, Ore.
Providence	W. P. Field	F. N. Tompkins, Brown University, Providence, R. I.
Rochester	A. E. Soderholm	Earl C. Karker, Mechanics Institute, Rochester, N. Y.
St. Louis	Fred D. Lyon	Ralf T. Toensfeldt, 311 City Hall, St. Louis, Mo.
San Francisco	R. C. Powell	A. G. Jones, 807 Rialto Building, San Francisco, Calif.
Saskatchewan	E. W. Bull	W. P. Brattle, Dept. of Telephones, Parliament Bldgs., Regina, Sask.
Schenectady	W. J. Davis, Jr.	W. E. Saupe, Bldg. No. 41, General Electric Co., Schenectady, N. Y.
Seattle	E A. Loew	C. E. Mong, 505 Telephone Building, Seattle, Wash.
Sharon	W. M. Dann	L. H. Hill, Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Southern Virginia	W. S. Rodman	J. H. Berry, 1338 Rockbridge Ave., Norfolk, Va.
Spokane	G. S. Covey	Richard McKay, Washington Water Power Co., Lincoln & Trent, Spokane, Wash.
Springfield, Mass.	R. P. King	J. Frank Murray, 251 Wilbraham Ave., Springfield, Mass.
Syracuse	W. C. Pearce	L. N. Street, College of Applied Science, Syracuse University, Syracuse, N. Y.
Toledo	A. H. Stebbins	Max Neuber, 1257 Fernwood Ave., Toledo, Ohio
Toronto	L. B. Chubbuck	W. L. Amos, Hydro-Elec. Power Commission, 190 University Ave., Toronto, Ont.
Urbana	C. A. Keener	J. T. Tykociner, 300 Electrical Laboratory, University of Illinois, Urbana, Ill.
Utah	John Salberg	D. L. Brundige, Utah Pr. & Lt. Co., Box 1790, Salt Lake City, Utah.
Vancouver	A. Vilstrup	C. W. Colvin, B. C. Elec. Railway Co., Hastings St., Vancouver, B. C.
Washington, D. C.	A. F. E. Horn	L. E. Reed, Potomac Elec. Pr. Co., 14th & C Sts., N. W., Washington, D. C.
Worcester	E. T. Harrop	Fred B. Crosby, 15 Belmont St., Worcester, Mass.
Total 51		

LIST OF BRANCHES

Name and Location	Chairman	Secretary	Counselor (Member of Faculty)
Alabama Polytechnic Institute, Auburn, Ala	J. D. Stewart	I. L. Knox	W. W. Hill
Alabama, University of, University, Ala	C. E. Rankin	Sewell St. John	
Arizona, University of, Tucson, Ariz	C. A. Rollins	J. W. Cruse	Paul Cloke

DIGEST OF CURRENT INDUSTRIAL NEWS

NEW CATALOGUES AND OTHER PUBLICATIONS

Mailed to interested readers by issuing companies

Watthour Meters.—Bulletin 71, 100 pp., entitled "Instructions for Sangamo D-5 Watthour Meters." Sangamo Electric Company, Springfield, Ill.

Tachometers.—Catalog 1700, 24 pp. Describes tachometers for recording and indicating purposes, applicable on all revolving machinery. The Bristol Company, Waterbury, Conn.

Motors.—Bulletin 323. Describes "Master" motors, consisting of a complete line of small motors to fit practically any current specifications. The Master Electric Company, Linden & Master Avenues, Dayton, Ohio.

Bus Connectors.—Catalog 26, 48 pp. Describes a unique line of high tension bus connectors. These devices are for connecting copper tubing and cable in all combinations. Many novel designs are included. Burndy Engineering Company, Inc., 10 East 43rd Street, New York.

Pyrometers.—Catalog 15, 80 pp. In addition to a comprehensive outline of the development of pyrometry, a chapter is devoted to the advantages of pyrometers for various industries and the economies effected. The Brown Instrument Company, Wayne & Windrim Streets, Philadelphia, Pa.

Welding Rods.—Bulletin, 24 pp., "Effect of Surface Materials on Steel Welding Rods." Includes a new arrangement of data on gas and electric filler rod, which shows by means of tables and specifications, uses and the comparative properties of the various types. Chicago Steel & Wire Company, 103rd Street & Torrence Ave., Chicago, Ill.

Oil Engines.—Catalog, 33 pp. Describes direct-injection oil engines for all purposes. The text matter, which consists of technical data and details of the "PO" oil engines of 55, 110 and 150 B. H. P. sizes, is profusely illustrated by forty-two illustrations of plant layouts, installation views, diagrams and engine details. Ingersoll-Rand Company, 11 Broadway, New York.

NOTES OF THE INDUSTRY

Ohio Brass Company Moves Chicago Office.—Announcement is made of the removal of the Chicago office of the Ohio Brass Company from 1217 to 1714 Fisher Building.

W. H. Perkins, who formerly represented the Trumbull Steel Company in the New England territory, is back again after a year's absence and in charge of their Boston Office at 141 Milk Street.

Packard Electric Company, Warren, O., announces the appointment of Harris & Butler, Real Estate Building, Philadelphia, as district managers for Packard transformers in the Philadelphia territory.

H. G. Pierce was made manager of the Berlin office of the International General Electric Company, succeeding L. A. Trone. Mr. Pierce has been with the International Company since 1917, when he had charge of sales in China.

Railway & Industrial Engineering Company, Greensburg, Pa., has purchased the property and building of the Penn Aluminum Company, adjoining their present plant. The building will be enlarged for additional storage space.

New Office for Delta-Star.—H. W. Young, president of the Delta-Star Electric Company, announces the opening of a new and larger office at 140 Cedar Street, New York, in charge of W. S. Nichols, assisted by P. H. Butler and A. R. Beger.

Personnel Changes in Timken Company.—T. F. Rose, formerly assistant manager of the Chicago branch of the Timken Roller Bearing Service & Sales Company, has been appointed branch manager of the Cincinnati office. H. C. Sauer has been appointed manager of the Detroit branch. Mr. Sauer was formerly assistant manager of the Cleveland branch. Fred G. Rumball, formerly branch manager of the Kansas City branch, has been promoted to the position of sales engineer, automotive division, of the Timken Roller Bearing Company. Mr. Rumball will have his headquarters at Cleveland with Edgeley W. Austin, assistant manager of sales. The position of branch manager at Kansas City will be filled by J. M. Carey, who has been promoted from the position of salesman under Mr. Rumball.

New A-C Starter.—A new starter is announced by the General Electric Company, Schenectady, N. Y., bearing the type designation CR-7055-A-1. It is a reversing primary resistor for squirrel cage induction motors. Two three-pole line contactors are provided with this starter. These contactors are electrically and mechanically interlocked and are mounted back-to-back on the panel. A magnetic time interlock provides a predetermined definite time of from one to three seconds between the closing of the line contactor and of the accelerating contactor. Two-point starting is provided by a resistor designed to conform to Electric Power Club classification No. 16. A temperature overload relay with an external resetting mechanism furnishes overload protection. The enclosing case is of sheet metal, semi-ventilated, and is provided with feet for wall mounting.

Synchronous Motor Control.—A complete self-contained oil-immersed automatic starter for 2300 volt synchronous motors has been developed by the Electric Controller & Manufacturing Company, Cleveland, O. This is built for across-the-line starting of slow speed motors and for reduced voltage starting of the higher speed motors. To start, a button is pushed, and as the motor approaches synchronous speed the field excitation is automatically applied. The reduced voltage starter consists of a welded boiler plate tank which contains an automatic double-throw switching mechanism, a power transformer for providing starting voltage, potential transformers for providing 220 volts for the master switch operating current and the current limit transition relay, which connects the motor to full voltage when it has been accelerated to approximately 85 per cent of synchronous speed. The equipment is complete in a single unit, which makes possible floor mounting of all the apparatus necessary for starting synchronous motors.

Building Program of $5,000,000 For Westinghouse.—The present building program for the expansion of facilities at various plants and offices of the Westinghouse Electric & Manufacturing Company will involve an expenditure of $5,525,000, according to T. P. Gaylord, acting vice-president of the company. The cost of the general office building now nearing completion at the Pittsburgh Works is $1,500,000. Additional construction is under way or will begin soon on the company's plants at Mansfield, Detroit, St. Louis, Springfield, Sharon and Derry.

Pyrex for High-Voltage Insulators.—The Corning Glass Works, Corning, N. Y., announces its entrance into the electrical transmission field with high-tension Pyrex insulators. The company states that many years of intensive research has proven that Pyrex insulators have the required qualities necessary for a perfect insulator. These qualities are said to be low temperature rise with uniform temperature throughout, transparency permitting ease of inspection, non-hygroscopic, permanent and uniform dielectric strength, quick drying surface, and the ability to withstand concentrated power arcs. Several thousands of these insulators are said to have been in service on the Montana Power system for about two years. At the present time the company is offering pin-type insulators of a one-piece design for operating voltages from 6,600 to 50,000. Development work is proceeding on suspension and flange or stack-type units and further announcements regarding these will be made later. Raymond W. Lillie is Manager of Power Line Insulator Sales, located at Corning Glass Works, 501 Fifth Ave., New York City. The main factory and offices are located at Corning, N. Y.

The Investigation of Engineering Education

On June 10, Dr. Jewett, National Secretary Hutchinson and the undersigned met in conference with Messrs. Wickenden and Hammond, representatives of the Society for the Promotion of Engineering Education, for the purpose of discussing the following findings and recommendations of the Board of Investigation and Coordination regarding Engineering Education:

"1. There is no present need for the further multiplication of degree-granting colleges of engineering. The moral influence of the colleges and of the national engineering societies should be used to discourage the multiplication of weak professional schools and to encourage the growth of schools devoted to vocational training for junior and intermediate forms of technical work.

"2. On the initiative of the S. P. E. E. the national engineering societies might properly cooperate with the colleges in defining an acceptable or recognized engineering college for the support of satisfactory educational standards among the colleges and for the guidance of the societies in applying the provisions of their constitutions and by-laws which relate to conditions of admission to membership and the recognition of student chapters and branches.

"3. Engineering colleges should be encouraged to give up the practise of awarding such professional degrees as "Civil Engineer," "Mechanical Engineer," and the like, for programs of academic work. On the initiative of the S. P. E. E. the national engineering societies might properly cooperate in recommending a basis for the awarding of professional degrees which would have the approval of the several professional societies and would be consistent with the requirements for entrance to a professional grade of membership.

"4. There is a strong sentiment in the professional societies in favor of engineering curricula which are only slightly or moderately differentiated from each other. The program of undergraduate work in the colleges should emphasize largely the broad foundations of engineering and should assume that much of the special training needed for particular types of engineering work should be obtained either by graduate study or in connection with active experience.

"5. It is desirable that there should be a standing council on engineering education; that the initiative toward this end should originate in the S. P. E. E., as representing the colleges; and that the national engineering societies should accept the invitation, if given, to appoint representatives in such a council."

The several conferees expressed themselves as being in sympathy with the above propositions. It was recognized, however, that this attitude would not commit either organization in an official way. The propriety of having national organizations of the engineering industries represented in the joint advisory council on engineering education was discussed, it being the sentiment that such representation would not be desirable at the outset because of the greater mutuality of interest existing between the professional societies and the engineering schools.

This conference was in response to a letter addressed by our Past President, Dr. Charles F. Scott, to Mr. Calvin W. Rice, Secretary of the Joint Conference Committee of the Founder Societies. I quote several passages from this letter:

"During the past two and one-half years this Society (S. P. E. E.) has been engaged in a comprehensive study of engineering education. Its broad purposes have been to elevate educational and professional standards and to bring about a closer relationship between the colleges, the engineering societies, and American industry. The Founder Societies have given support and rendered advice to this enterprise through a group of educational councilors. The societies have appropriated funds for conducting special studies of educational matters relating to the several major engineering fields. These studies have paralleled similar studies made by and in the colleges themselves.

"The Carnegie Corporation has financed the enterprise for a period of three years. We now approach the end of that period. Thus far we have secured the active and hearty cooperation of practically all of the engineering colleges and we have made a comprehensive and accurate analysis of the present and past state of engineering education. We have also reached definite conclusions upon which to base recommendations as to the future course of engineering education. It remains to put these recommendations into effect. We believe that the undertaking should continue beyond the stage of fact-gathering and analysis to which it has thus far been largely devoted and that its next stage should be one of effective action. We believe that the national engi-

neering societies should share with the colleges the responsibility for the support and direction of such effort.

"To this end we hope we may obtain from the Founder Societies endorsement of our purpose to continue the enterprise and to bring about constructive action. We therefore suggest that each of the Founder Societies participate in its financial support through a small appropriation. We feel that such support will be of great importance in two ways: first, in giving the societies a share in the direction of the enterprise, and second, in assisting us to obtain additional support from other sources. Since our undertaking has been essentially of the nature of engineering research it would seem appropriate for Engineering Foundation to aid in financing it by appropriation and assistance in obtaining contributions."

Dr. Jewett, Secretary Hutchinson, and the undersigned approved in principle Mr. Wickenden's findings and agreed to recommend them to Board of Directors of A. I. E. E.

The President of A. I. E. E. and its National Secretary attended a meeting of the Joint Conference Committee called by Secretary Rice for June 15, 1926. At this conference the following resolution was adopted:

VOTED: to approve the continuance of the research in the field of engineering education now being conducted by the Society for the Promotion of Engineering Education, which research would otherwise be terminated December 31, 1926, and each President in turn is to recommend to his Board a small appropriation, say approximately ten cents per student in the respective branch of engineering corresponding to the field of endeavor of each of the four Societies. This would approximate annual appropriations as follows:

American Institute of Electrical Engineers	$1,800.
American Society of Civil Engineers	1,600.
American Society of Mechanical Engineers	1,200.
American Institute Mining & Metallurgical Engineers	250.

It is further understood that this approval is limited to a program which it is expected would be concluded within two years.

This whole subject was laid before the Board of Directors of A. I. E. E. at its meeting at White Sulphur Springs on June 23. At this meeting, the following telegram was received and read:

Society Promotion Engineering Education rejoices in splendid cooperation already accorded and the support now proposed by engineering societies and Engineering Foundation in movement to broaden develop and enrich engineering education. Convention at University of Iowa earnestly hopes governing bodies of societies will approve recommendations of their Presidents.

(Signed) Charles F. Scott.

The Board of Directors recommended to the Finance Committee of A. I. E. E. to provide in its budget for the years 1927 and 1928 appropriations of approximately $2000 for the support of the splendid enterprise in which the membership of A. I. E. E. is deeply interested.

I do not hesitate to endorse every sentiment in this matter expressed by our Past President, Charles F. Scott.

M. I. PUPIN.

Some Leaders of the A. I. E. E.

H. B. Buck, twenty-ninth president of the A. I. E. E., 1916-1917, was born in New York City, May 7th, 1873. He graduated from Yale University in 1894 with the degree of Ph. B. and received his degree of E. E. from Columbia School of Mines in 1895. The year 1895-1896 was spent as a student in the shops of the General Electric Company at Schenectady, and during this period, Mr. Buck did much experimental work on a-c. apparatus for the great scientist, Doctor Steinmetz.

From 1896 to 1900, Mr. Buck was assistant to the chief engineer of the Lighting Department of the General Electric Company, Schenectady, in which capacity he had much to do with the introduction of high-tension, a-c. distribution in many of the large central stations of this country, he traveling extensively throughout the United States to accomplish this work. During that same period, he also had charge of the experimental work which led to the development of the oil switch and other high-tension devices which furthered power operation by alternating current.

In 1900 he was chosen chief electrical engineer of the Niagara Falls Power Company and allied interests at Niagara, having entire charge of electrical engineering in the design and construction of powerhouse No. 2, on the American side of the Falls and the Canadian Niagara Power Company's plant on the Canadian side; also the terminal stations at Buffalo, and engineering in connection with the distribution of Niagara power in Niagara, Tonawanda and Buffalo. In 1906, in cooperation with Mr. E. M. Hewlett, at Niagara Falls, Mr. Buck carried on experimental work on high-tension insulators which resulted in the development and introduction of the suspension insulators now in universal use.

Since 1908 Mr. Buck has been vice-president of Viele, Blackwell and Buck, New York City, engaged in the design and construction of hydroelectric and steam power plants and large transmission systems both in the United States and Canada. Among these might be mentioned work for the Great Western Power Company of California, the Appalachian Power Company, the Northern Ontario Light & Power Company, the Great Northern Power Company and many others.

In 1925 the International Commission made him consulting engineer on the investigation of the development of some 4,000,000 h. p. at various sites on the St. Lawrence River between Ogdensburg and Montreal.

Regenerative Braking for Direct-Current Locomotives

BY A. BREDENBERG, JR.

Non-member, A. I. E. E.

Synopsis—*This paper gives a comparative study of several d-c., regenerative braking systems now in successful operation. The general characteristics of regenerative braking, including advantages, limitations and functions are briefly discussed. The principal points covered in the descriptions of the various systems are: method of field excitation during regeneration, compensation for sudden changes in line voltage or grade, method of control, operating characteristics and relative complication of equipment.*

Several systems are described in which the regenerating motor fields are excited by a separate generator provided for that purpose, and then other systems are described in which the fields are excited by one or more of the traction motors. Under the former heading are included C. M. & St. P. freight locomotive with a line driven motor-generator set for excitation, the Mexican locomotive with a dynamotor-driven, motor-generator set for excitation and the axle generator system. The applications described under the latter heading are the C. M. & St. P. gearless passenger, the Paulista and the Spanish Northern locomotives.

A comparison is made of these two methods of field excitation, based on a six-motor, two-speed, 3000-volt locomotive. Curves are included illustrating the speed-braking characteristics and also the motoring characteristics. The conclusions drawn from this comparison are that, in general, the separate excitation system is to be preferred on account of the greater braking effort and greater speed range provided. Since the motor excitation system can be provided with less additional expense, it is desirable to consider this method when the expense of the separate excitation system does not seem justifiable.

It is not the purpose of this paper to give an exhaustive discussion of the question of regenerative braking, but to make a comparative study of some of the systems now in successful operation on direct-current locomotives.

General Characteristics

Whenever it is proposed to electrify a railroad, where grades exceeding 0.6 per cent form an appreciable part of the line, usually the possibility of applying regenerative braking is considered on account of its marked advantages. These are, briefly, as follows: (a) Reduced wheel- and brake-shoe wear; (b) increased safety due to reduced tire heating and brake-shoe wear and to the fact that duplicate braking systems are provided; (c) higher average speed descending grades, since a very uniform speed can be maintained; (d) elimination of delays due to inspections, worn out brake shoes, etc.; (e) saving of power returned to the line, and (f) increased comfort to passengers as a result of the uniform speed and elimination of noises and shocks caused by the air-brake system. Against these advantages must be balanced the increased weight, cost, and maintenance of the equipment.

Although regenerative braking may be used to reduce train speeds to a certain extent, and systems have been designed to slow down a train or car to very low speeds, yet the primary purpose of this method of braking as applied to heavy traction service is to hold the train at a uniform speed on a given down grade. Regenerative braking should not be overemphasized as an emergency braking system. This method of braking can only be applied to the locomotive, whereas, in the air-brake system, the brakes may be applied to every car in the train. Therefore, regeneration does not replace the air-brakes or lessen their required reliability but it should be considered as a means of braking, supplementing the air-brakes with some very decided advantages as outlined.

Of course, regenerative braking is particularly applicable to long heavy mountain grades and is generally used in such service because of its obvious advantages. It is applicable to comparatively light or short grades provided the results obtained are commensurate with the extra cost incurred.

In order to raise the voltage of a d-c. series motor to make it return power to the line, it is necessary to excite separately the series field and to control this excitation so that smooth operation is obtained regardless of changes in line voltage or grade.

Methods of Field Excitation

There are two general methods of exciting the motor fields and both of these have been successfully applied. One method is by the use of a generator which may be driven by a motor operating from line voltage or from a dynamotor. Also, it might be mechanically driven from an idle axle of the locomotive.

The other method is to use one or more of the traction motors to excite the fields of the remaining motors. This method may be sub-divided further according to the method of controlling the exciter field. Thus, in one case, the exciter field is controlled by contactors, resistors, etc., especially provided for that purpose, while in the other case, control of the exciter field is obtained by means of the same contactors and resistors that are used in accelerating the locomotive.

C. M. & St. P. Freight Locomotives

The method of exciting the regenerating motor fields by means of a motor-generator set operated from the line voltage was first put into commercial use on the

1. Railway Equipment Engineering Dept., General Electric Co., Schenectady, N. Y.

Presented at the Annual Convention of the A. I. E. E., White Sulphur Springs, W. Va., June 21-25, 1926.

Chicago, Milwaukee and St. Paul 3000-volt freight locomotives. By reference to Fig. 1, which shows the regenerative connections of one-half of one of these locomotives, it may be seen that the exciter is so connected that the exciter armature current is the sum of the motor field current and the regenerated current. Control of the exciter field is obtained by means of a motor-operated rheostat, automatically controlled by a current-limit relay which is connected in the exciter armature circuit. The current-limit relay thus is responsive to the sum of the motor armature and field currents. Control of the braking speeds is obtained by changing the setting of the current-limit relay by means of the braking handle on the master controller.

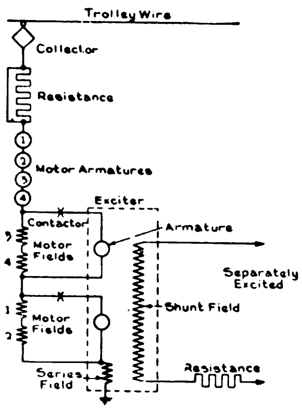

FIG. 1—DIAGRAM OF C. M. & ST. P. FREIGHT LOCOMOTIVE

Compensation for sudden surges in current, due to changes in line voltage or grade, is obtained by a combination of several factors, viz., the differential series field of the exciter, the exciter armature reaction, and the resistance drop in the exciter armature circuit. For example, assume a sudden decrease in line voltage. This will tend to rapidly increase the regenerated current and consequently the current through the exciter armature. The compensating factors will then operate as follows: The differential series field and the exciter armature reaction will tend to weaken the exciter field and reduce the exciter voltage, thus reducing the motor field current, while the increased resistance drop will cause the exciter armature circuit to absorb more of the exciter voltage and thus further reduce the field current and generated voltage of the traction motors. Likewise, a sudden decrease in regenerated current will be compensated for in just the opposite manner. Thus, the inherent characteristics of the exciter circuits prevent excessive surges of current and torque and allow time for the circuits to readjust themselves to the changed operating conditions.

MEXICAN LOCOMOTIVES

Another application of the method of exciting the motor fields by means of a separate motor-generator set is that of the Mexican Railway, 3000-volt locomotives. In this case, the regenerative exciter is driven by a 1500-volt motor, which is connected to the mid-point of a 3000/1500-volt dynamotor. Connections for this locomotive are shown in Fig. 2. Here the exciter carries the motor field current only. Control of locomotive speeds is obtained by adjusting the exciter voltage by means of a variable resistance in the exciter field circuit. This adjustment is obtained directly by means of the braking handle of the master controller.

Compensation against sudden surges in line current is provided for by balancing resistances which carry the sum of the field and armature currents. Thus, if the line voltage drops suddenly, it will tend to produce a rapid increase in regenerated current. The increase in current causes an increased voltage drop across the balancing resistance which causes a decreased voltage and current in the motor field circuit. This reduces the regenerated voltage of the motors, thus preventing an excessive change in regenerated current. Similarly, when passing from one control step to another, the balancing resistance aids in producing smooth operation by reducing current and torque increments between steps.

COMPARISON OF C. M. & ST. P. AND MEXICAN LOCOMOTIVES

By comparing these applications, it will be seen that in one case the exciter carries the sum of the motor armature and field currents while in the other case the exciter carries the field current only. This means that, in the latter case, the exciter armature current will be halved. At the same time, the exciter voltage will be increased as the exciter must overcome the voltage drop in the motor fields and also in the balancing resistance. Experience has demonstrated the fact, however, that the drop through the balancing resistance can be held to such a value that the net result is a reduction in kilowatt capacity required of the exciter.

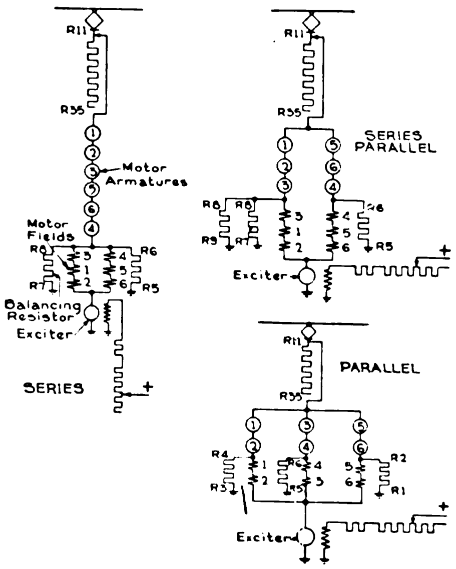

FIG. 2—DIAGRAM OF MEXICAN LOCOMOTIVE

In the first system described compensation is ob-

tained by means of exciter differential field, armature reaction and resistance drop. In the second system, a resistance alone is used since tests and operating data have demonstrated that a very effective compensation can thus be provided. The second system will tend to be less efficient on account of the losses in the balancing resistances. A much simpler control is thus provided, however, and furthermore it is very easy to make adjustments by providing taps in the balancing resistances.

Compared with the other type, the system used on the Mexican locomotives has the characteristic of relatively small changes in speed with regard to changes in the braking effort required. The result is that changes in grade or curvature will cause smaller speed changes in this case than in the C. M. & St. P. System. In brief, the Mexican system tends toward a constant speed characteristic while the C. M. & St. P. System tends toward a constant torque characteristic.

The ideal characteristic for regenerating motors would be a characteristic similar to that obtained in motoring operation with a series motor where the armature and field currents are equal throughout the operating range. This would give a very stable electrical characteristic but an extremely unstable speed characteristic, as the braking effort would decrease very rapidly with increases in speed.

The ideal characteristic from a mechanical standpoint would be one in which the speed on any controller notch is held constant regardless of changes in braking effort required. Such a characteristic would be approximated with constant field excitation. Such a system would be very unstable electrically, however, as very large changes in armature current would occur with small changes in speed. This would be particularly undesirable at high speeds on account of the relatively weak fields required.

In practise, a compromise must be made between these two extremes. From the standpoint of train operation, it is very desirable to obtain a uniform speed for any given controller notch. Some speed variation must be allowed, however, in order to obtain the desired stability of the motors. Such is the case with the two systems described above. In each case, for any given controller notch within the regenerating range of the motors with increases in speed a sufficient increase in braking effort is obtained to give mechanical stability, but, at the same time, the speed regulation is not made so close as to sacrifice the desired electrical characteristics.

With the more constant speed characteristic of the system used on the Mexican locomotives, very little manipulation of the master controller is required to hold the train at a practically constant speed. This has been demonstrated in actual operation on the Mexican Railway. The electrified section of this railway is 45 kilometers long and regeneration is obtained for about two-thirds of this distance, the grade being about 4.7 per cent the greater part of the way.

The principal advantage of the Mexican system is its simplicity. Compensation for line-voltage changes is obtained by means of a simple resistance, and control of the regenerating speeds is obtained by hand control of a resistance in series with the exciter field. No relay or motor-driven rheostat is used. This will reduce the first cost of the system and keep the maintenance required down to a minimum.

Development of Method of Control of Exciter Field

The steps in the development of the method of controlling the exciting generator field included experiments with the sensitive type of regulator used with stationary units. Later, the motor-operated field rheostat was used and finally direct hand control of the field was adopted, compensation against voltage and speed fluctuations being obtained by the inherent characteristics of the motor field circuits without the addition of any regulator or moving parts.

Axle Generator System

The axle generator system may be considered as a motor-generator set system in which the motor of the motor-generator set is replaced by the axle driving mechanism. The same method of control may be used in either case.

The principal differences between an axle generator system and the corresponding motor-generator set system are that the axle generator is necessarily a slow-speed machine, it varies in speed with the speed of the locomotive, and the driving torque of the axle generator is available to aid in braking the train.

Assuming that the same connections are used for an axle generator system as are used on the Mexican locomotive (Fig. 2), it may be readily seen that, with an increase in speed due to an increase in the grade, the regenerated voltage and current will tend to increase due to the increase in speed of the motors themselves and also to the increase in speed of the axle generator which thus tends to increase the motor field current. This helps to give a very close speed characteristic for any given excitation of the axle generator field, such being desirable provided the electrical stability of the motors is not lessened.

Regarding the added braking effort of the exciter, this might prove an advantage in freight service where it is often desired to handle a considerably heavier train down grade than could be hauled up the same grade by one locomotive. In this case, however, it will probably be necessary to use the air brakes on the train in conjunction with the regenerative braking so that little would actually be gained from the additional braking effort obtained from the axle generator. Furthermore, there must be an idle axle available to drive the exciting generator. This is usually the case with passenger

locomotives. On freight locomotives, however, there are very often no idle axles, as illustrated by the Mexican and Spanish Northern locomotives and the Paulista freight locomotives, where every axle drives a traction motor.

Another limitation of the axle generator is that, due to its low speed, it must be of relatively large size. In addition, it must deliver practically the same output over a wide range of speeds, which will tend to compromise the design and complicate the control.[7] Furthermore, the axle generator is mounted close to the track and thus is subject to more abuse, dust particles, etc., than a generator mounted in the locomotive cab.

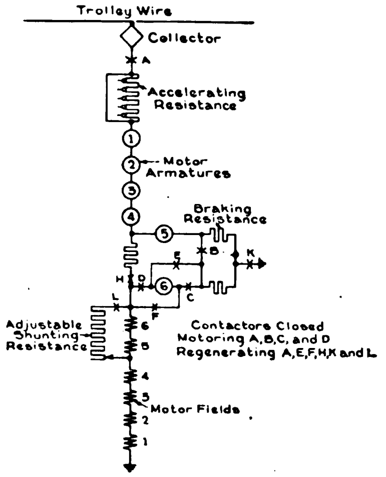

FIG. 3—DIAGRAM REGENERATING CONNECTIONS OF C. M. & ST. P. GEARLESS PASSENGER LOCOMOTIVE

C. M. & ST. P. GEARLESS PASSENGER LOCOMOTIVES

In order to eliminate the use of a separate generator for field excitation, the method of using one or more traction motors as a regenerative exciter was developed. The first application of this system to heavy-traction service was on the C. M. & St. P., 3000-volt, gearless, passenger locomotives. Fig. 3 shows the regenerating connections for one-half of the locomotive. The two halves may be operated in series or in parallel when regenerating so that two combinations of regenerating motors are obtained, one with eight motors in series and the other with two parallel groups, of four motors in series, in each. In each six-motor group, two of the traction motors are used to excite the fields of all six motors. Control of the excitation is obtained by means of a variable resistance, which shunts the fields of the exciting motors. This resistance is adjusted by means of contactors controlled by the braking handle of the master controller.

From the connections, it will be seen that the sum of the field and armature currents of the regenerating motors passes through the two exciter armatures which are connected in multiple and that an external resistance is connected in series with each of the exciter armatures. This system thus provides an inherent regulation against line-current surges which is in effect a combination of the C. M. & St. P. freight and the Mexican systems. That is, the sum of the armature and field currents of the regenerating motors passes through balancing resistances and also through the exciter armatures. An effective means of compensation against surges is thus provided.

A further simplification of the apparatus required for regeneration may be obtained with the traction-motor exciter system by using the same resistances and contactors for controlling the exciter during regeneration that are used during acceleration of the locomotive. This system is now in successful operation on the Paulista locomotives (four-motor, 3000-volt) and on the Spanish Northern locomotives (six-motor, 3000-volt). On the Paulista locomotives, one traction motor is used to excite its own field and the fields of the other three motors which are connected in series to the line. On the Spanish Northern locomotives one traction motor is used to excite its own field and the fields of the other five motors which are connected in series to the line.

PAULISTA LOCOMOTIVES

Fig. 4 shows the schematic connections of the Paulista locomotive both motoring and regenerating. It will be seen that there are two motor combinations motoring, one with all four motors in series with 750 volts applied per motor and the other combination with two groups of two motors in series in each with 1500 volts applied per motor. There is one regenerating combination with

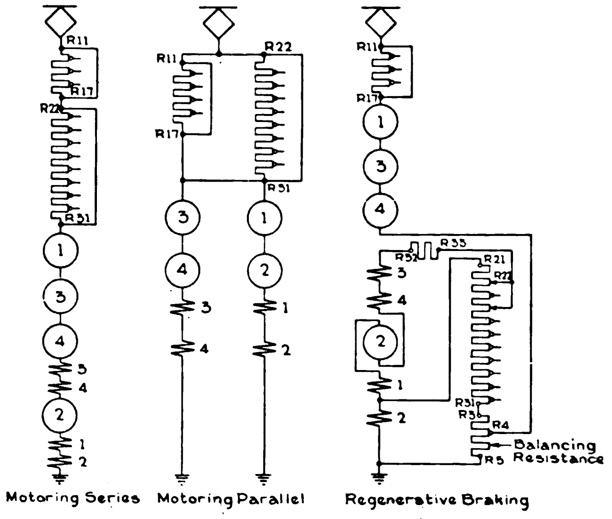

FIG. 4—DIAGRAM OF SCHEMATIC CONNECTIONS OF PAULISTA FREIGHT AND PASSENGER LOCOMOTIVE

the three regenerating motors connected in series with a normal voltage of 1000 volts per motor. By referring to the resistance symbols it will be seen that part of the accelerating resistance is connected in series with the regenerating motors. This resistance is used in connecting the motors to the line when establishing the regenerative connection. It is short-circuited during regeneration. The remainder of the accelerating resistance is connected in the motor field circuit and is

thus used to control the regenerative operation. Some additional resistance and additional contactors are required but it is to be noted that an appreciable saving in equipment is made by using the accelerating resistance and contactors for control of the exciter field.

Practically the same method of compensation for line current surges is used as on the Mexican locomotives. A balancing resistance is connected in the circuit so as to carry the sum of the line current and the exciter field current. This exciter field current is also part of the regenerating motor field current so that the compensation is obtained in two ways; directly by the effect of the balancing resistance on the regenerating motor fields, and indirectly by the effect of the balancing resistance on the exciting motor field.

Spanish Northern Locomotives

On the Spanish Northern locomotives there are two motoring combinations, one with all six motors in series

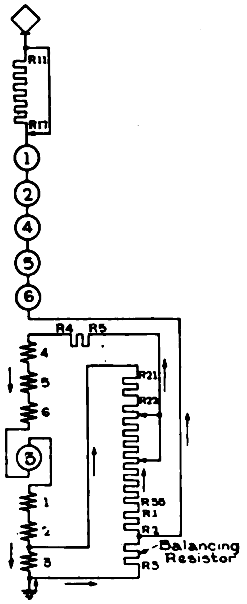

Fig. 5—Diagram of Regenerating Connections of Spanish Northern Locomotive

with 500 volts applied per motor and the second with two parallel groups of three motors in series in each with 1000 volts applied per motor. Fig. 5 shows the regenerating connections of this locomotive. One of the six motors is used to excite its own field and the fields of the other five motors which are connected in series to the line with a normal voltage of 600 volts per motor. The regenerating system is otherwise identical with that of the Paulista locomotives.

Comparison of Methods of Field Excitation

In order to obtain a comparison of the system using a separate generator for field excitation and that using traction motor excitation a study was made of the operating characteristics of a locomotive similar to the Spanish Northern, six-motor, two-speed, 3000-volt locomotive as compared with the same locomotive with a motor-generator set for field excitation. For motor excitation, then, there will be one regenerating combination with one traction motor exciting the other five, all connected in series. For separate excitation there will be two regenerating combinations, one with all six motors in series and the second with two parallel groups of three motors in series in each, these combina-

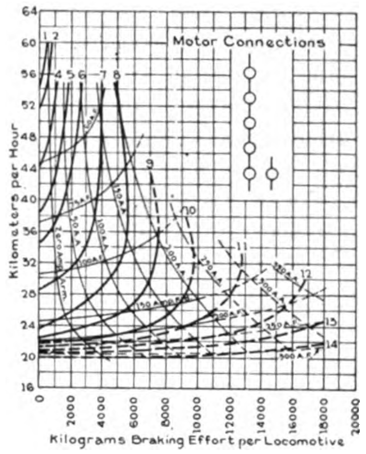

Fig. 6—Speed-Braking Effort Curves for 86-Ton, 6-Motor, 3000-Volt Locomotive with Traction Motor Excitation

tions being the same as those obtained while motoring.

In comparing the operating characteristics of these two systems of regeneration, the main points to be con-

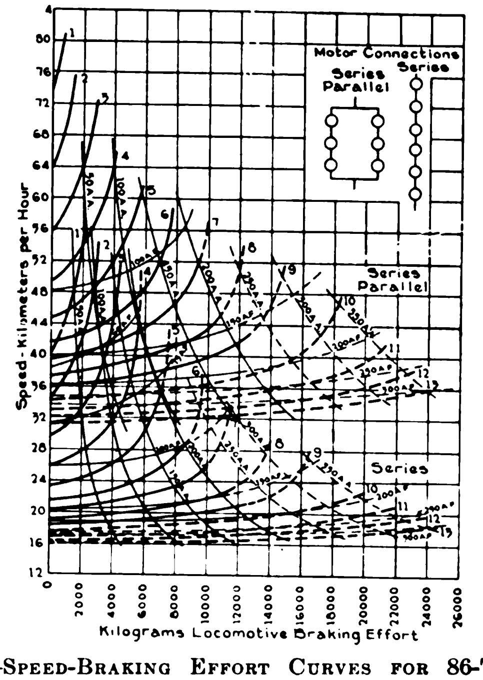

Fig. 7—Speed-Braking Effort Curves for 86-Ton, 6-Motor, 3000-Volt Locomotive with Separate Excitation

sidered are as follows: range of operating speeds, train weights which may be handled, slope of grades, mileage on which regeneration can be used, and reliability.

Figs. 6 to 8 inclusive illustrate the speed-braking effort characteristics obtained with the two systems. Figs. 6 and 7 give the relation between speed and

braking effort for each step of the braking handle on the master controller, and Fig. 8 is a composite diagram which shows the range of speeds and braking efforts which may be obtained in each case. The shaded areas in Fig. 8 give the continuous operating ranges while the unshaded areas give the ranges within which the locomotive may regenerate for short periods. This diagram also shows the speed-traction effort curves for motoring operation in each of the two motoring connections. In each case the full field and two reduced field characteristics are given. The tractive effort and speeds at the continuous current rating are also indicated.

Two regenerating speed ranges are obtained with the separate excitation system whereas one speed range is

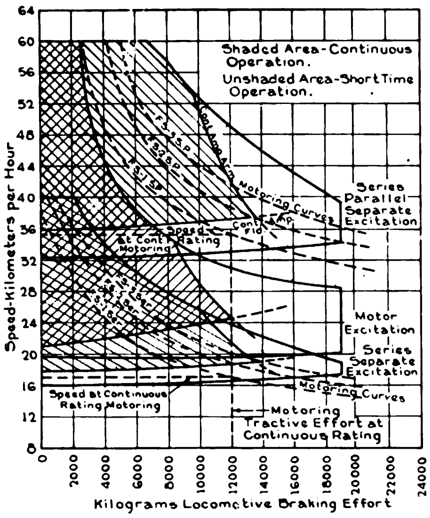

Fig. 8—Comparison between Separate and Traction Motor Excitation for 86-Ton, 6-Motor, 3000-Volt Locomotive

obtained with motor excitation, this latter speed range being intermediate to the two speed ranges with separate excitation.

In analyzing these curves, it is to be noted that with the same line voltage, the same motor combination, and the same armature and field current, a slightly higher speed will be obtained when regenerating than when motoring. The reason for this is the reversal of the effect of resistance drop in the motor circuits. Under the same conditions the braking effort regenerating will be appreciably greater than the corresponding tractive effort motoring on account of the reversal of the effect of the motor losses on the torque at the driving wheels. Furthermore, with a given torque at the driving wheels, it will be possible to handle a considerably heavier train down grade than up grade since the train and curve friction oppose the locomotive ascending the grade while they assist the locomotive when descending.

With the separate excitation system, therefore, the regenerating speeds will be a little higher than the motoring speeds with the same motor combination, voltage, and currents. With motor excitation of fields, in this particular case, the regenerating speed at the continuous-current rating of armatures and fields will be about 70 per cent of the corresponding motoring speed. As a rule, the double-speed range is to be preferred unless it is desired to descend the grade at a lower speed than used in ascending. In the latter case the speed range of the motor excitation system will probably be more suitable.

From an analysis of the curves, it may be seen that for a given armature and field current of the regenerating motors a greater braking effort is obtained with the separate excitation system than with the motor excitation system. The reason for this is that, in the former system, the full braking effort of all six motors is available while in the latter the full braking effort of five motors is available and a fraction of the full braking effort of the exciting motor. The result is that greater train weights can be handled down a given grade with the separate-excitation system than with the motor-excitation system.

The following conclusions in regard to operating characteristics may be stated as a result of the comparison of these two systems:

1. With motor excitation in general, on all grades, the same train can be handled down hill as up hill, but at reduced speeds. This reduction in speed will be comparatively small for light grades but will increase as the grade increases.

2. With separate excitation at continuous current, armatures, and fields, a considerably heavier train may be handled down hill than up hill and at a slightly greater speed. The percentage difference in the size of the train thus handled decreases as the grade increases.

3. With separate excitation, a train may be handled down grade at a considerably higher speed than this train can be hauled up the same grade, assuming that the safe operating speed is not exceeded. The percentage difference in these speeds decreases as the slope of the grade increases.

This study indicates that motor excitation may best be applied to a line with comparatively light grades; *e. g.*, one and one-half per cent and under. It will still be applicable to heavier grades if these grades are short and little time is lost on account of slower speeds, or if the slower speed obtained will not handicap the schedule speed desired.

Regeneration with separate excitation is particularly applicable to heavy grades; *e. g.*, two per cent and over, when the length of these grades is an appreciable part of the total length of the line. It is also preferable to use this system for lighter grades when it is necessary to take advantage of the highest speeds possible down grade.

Concerning reliability of operation, there will be little difference if any, between the two systems, assuming that the same rugged type of equipment is used in each

case and that the same method of compensation is used as has already been described.

It is evident that the additional expense of providing for regeneration is less with motor excitation than with separate excitation since in the former case less additional equipment is required.

It is to be noted that the foregoing comparison covers the specific case of a two-speed, six-motor locomotive. The same general considerations would apply to a similar comparison for any two-speed locomotive. For locomotives with more than two motoring speeds or combinations, there will be cases where motor excitation cannot be so readily applied on account of the limited speed range which can be obtained. This would be the case, for example, with a three-speed locomotive such as the Mexican locomotive. The logical regenerating combination in this case would be that of one motor acting as an exciter for the other five motors in series. The speed range thus obtained would be quite low in comparison with the highest motoring speed which is obtained with three parallel groups of two motors in series in each. Other combinations could be worked out for this type of locomotive, but with a reduction in braking torque which would, of course, be undesirable. To other types, such as the C. M. & St. P. gearless passenger locomotive, motor excitation can be more readily applied. This locomotive has four motoring combinations; viz., with twelve, six, four and three motors in series across the line. Two regenerating combinations are obtained with eight regenerating motors in series and two parallel groups of four motors in series. Thus, a better speed-range regenerating is obtained than with the six-motor, three-speed locomotive cited above.

It is not within the scope of this paper to discuss all possible combinations to which motor excitation may be applied. From the foregoing discussion, however, the conclusion may be drawn that this type of regenerative braking may be readily applied to two-speed locomotives in general and in some cases to locomotives with a greater number of motoring combinations.

In the foregoing discussion, it has been attempted to present the characteristics of certain types of regenerating systems which have been successfully applied to d-c. locomotives. In general, it may be stated that a system with a separate generator for excitation of the motor fields is to be preferred as this gives the same motor combinations regenerating as motoring and furnishes the full torque of each motor for braking the train. Since the motor excitation system can be provided with less additional expense, however, it is desirable to consider this method when the expense of the separate excitation system does not seem justifiable. In any application, before a decision is reached as to the type of braking system to be used, a thorough study should be made of all the contributing factors.

The High-Speed Circuit Breaker in Railway Feeder Networks

BY J. W. McNAIRY[1]

Non-member

Synopsis.—*A method of isolating grounded sections of extensive feeder networks supplying power to railways without disturbing the power supply to other sections has long been desired by railway engineers. This has been successfully accomplished by utilizing the inherent characteristics of the magnetic type of high-speed circuit breakers in the manner described in this article. These characteristics are (a) high-speed operation, (b) discriminating characteristic, (c) reduction in trip point with reduction in line voltage, (d) polarized characteristic.*

A description of an experimental investigation on an equivalent network for a representative section of feeder system, made up by using reactors and resistors, has been given. Complete selective operation, isolating defective feeder without disturbing the power supply to interconnected feeders, was obtained for all locations of the short circuit.

Breakers of the type used successfully on d-c. networks can be applied to a-c. networks and the advantages of high-speed protection realized on this type of system. High-speed operation is very effective in reducing telephone interference during short circuits on the a-c. railway system.

Introduction

The development of the high-speed circuit breaker and its application to the d-c. railway system has contributed greatly toward reduced maintenance and increased reliability of the power supply of this system. The effectiveness of the high-speed operation of this device in reducing the duration of short circuits and limiting the current, thereby eliminating flashovers of commutating apparatus and reducing the damage from arcs at points of fault, has been well recognized for a number of years. The elimination of flashovers and the reduction in the damage to windings of motors and other apparatus, connecting cables and mechanical equipment coming into contact with fallen contact lines or faulty cables, has reduced to a minimum the duration of power interruptions from this source.

1. Railway Equipment Engineering Department, General Electric Co., Schenectady, N. Y.

Presented at the Annual Convention of the A. I. E. E., White Sulphur Springs, W. Va., June 21-25, 1926.

With a few minor exceptions, high-speed circuit breakers applied to d-c. railway networks have been of the magnetic type, one form of which is shown by Fig. 1. This type involves the principle of a contact arm held in the closed position against a strong spring by a holding armature across the poles of an electromagnet. A tripping coil is interposed between the holding coil and the armature and is so connected that current through this coil exerts a m. m. f. to reduce the flux in the retaining armature, at the same time increasing the flux through a suitable magnetic by-pass circuit without an appreciable change in the flux through the

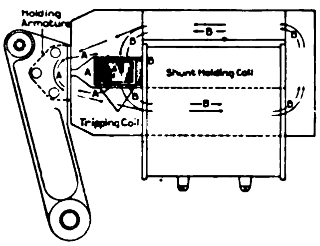

Fig. 1a

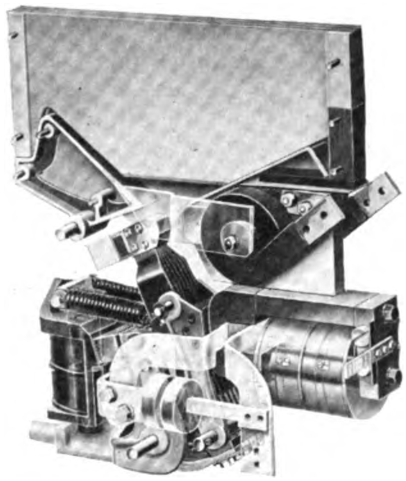

Fig. 1 b

1a—Magnetic Circuit of the Holding and Tripping Coils of the High-Speed Circuit Breaker

1b—Phantom View of a 600-Volt, D-C., High-Speed Circuit Breaker

core of the main holding coil. As the tripping current is increased, the flux is shifted in this manner from the holding armature to the magnetic by-pass circuit without the necessity of changing the flux interlinking the main holding coil. The effectiveness of this arrangement is such that the armature is released practically instantaneously when current in the trip coil reaches a predetermined value, regardless of the rate at which this current is increasing.

There are certain inherent characteristics in this type of circuit breaker which introduce possibilities for selective operation between breakers applied to a d-c. railway network, in case of short circuits, in such a way as to isolate defective feeder sections without the interruption even momentarily, of the power supply, to interconnected sections. The results obtained by proper utilization of these characteristics are comparable to those obtained on the usual a-c. networks by selective relay systems of the various well-known types.

The remainder of this article furnishes a detailed explanation of these characteristics and the methods of utilizing them, together with a description of the results obtained during an experimental investigation on a representative network.

Characteristics of the Magnetic Type High-Speed Circuit Breaker

The following inherent characteristics of the magnetic type of high-speed circuit breaker contribute most to the solution of problems of selective operation on a d-c. railway network:

a. High-speed operation

b. Discriminating characteristic providing a reduction in the trip point during a rapid current rise

c. Reduction in trip point with a reduction in line voltage

d. Polarized characteristics.

I. High-Speed Operation

In order to fully protect commutating apparatus in the d-c. railway substation, machine breakers must operate sufficiently fast to prevent flashover in case of short circuits inside of the station. While short circuits inside of station feeder breakers occur infrequently, without high-speed operation of protecting breakers, the current is relatively great and the resultant damage to substation apparatus is likely to be serious. This consideration automatically precludes the use of relays or any other selective system which delays the operation of such circuit breakers even slightly under short-circuit conditions.

The selective operation of the magnetic type of high-speed breaker is based upon an arrangement whereby the current is limited by the breaker or breakers supplying the faulty feeder directly, before the trip point of similar breakers supplying interconnected feeders, or the machine breakers in the substation is reached. During d-c. transients with an initial current rise of hundreds of thousands of amperes a second, the speed of operation of the breakers feeding such a short circuit must be relatively high. This is essential in order that advantage may be taken of conditions or arrangements whereby the trip current of one breaker is reached in advance of the others. These breakers must operate fast enough to limit the current before the trip point of the remaining breakers is reached. The speed of operation of the magnetic type of high-speed breaker designed to operate sufficiently fast to prevent flashovers of commutating substation apparatus is sufficient for such an application.

II. Discriminating Characteristic

The discriminating characteristic of the magnetic type of high-speed circuit breaker is obtained by connecting

an inductive shunt in multiple with the tripping coil, the total current through the breaker being distributed between these two circuits. The distribution of a slowly rising current between the trip coil and shunt is determined by the resistance, (and of a rapidly rising current by the inductance,) of the two parallel circuits.

The trip point of a circuit breaker so equipped can therefore be made a function of the rate at which the current is increasing.

Calculations of Current Distribution Between Tripping Coil and Its Shunt

Where the constants of the external circuits are

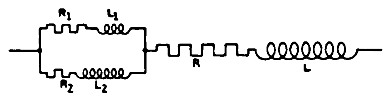

Fig. 2—Graphical Representation of the Resistance and Inductance of the Trip Coil of a High-Speed Circuit Breaker in Parallel with its Shunt and the Combination in Series with a Feeder

known, the current through the trip coil at any instant can be calculated as follows:

Referring to Fig. 2,

L_1 = Inductance of tripping coil
L_2 = Inductance of tripping coil shunt
L = Inductance of the external circuit
R_1 = Resistance of tripping coil
R_2 = Resistance of tripping coil shunt
R = Resistance of external circuit
I_m = Final current external circuit
= E/R where E applied voltage
t = time

$$I_1 R_1 + L_1 \frac{d I_1}{d t} = I_2 R_2 + L_2 \frac{d I_2}{d t} \qquad (1)$$

$$I_2 = I - I_1 \qquad (2)$$

$$\frac{d I_2}{d t} = \frac{d I}{d t} - \frac{d I_1}{d t} \qquad (3)$$

L_1, L_2, R_1 and R_2 are negligibly small in comparison with L and R;

$$\therefore I = I_m \left(1 - e^{-\frac{R}{L} t}\right) \qquad (4)$$

Substituting (4) in (2):

$$I_2 = I_m \left(1 - e^{-\frac{R}{L} t}\right) - I_1 \qquad (5)$$

Also from (4):

$$\frac{d I}{d t} = I_m \frac{R}{L} e^{-\frac{R}{L} t} \qquad (6)$$

Substituting (6) in (3):

$$\frac{d I_2}{d t} = I_m \frac{R}{L} e^{-\frac{R}{L} t} - \frac{d I_1}{d t} \qquad (7)$$

Substituting (5) and (7) in (1):

$$L (L_1 + L_2) \frac{d I_1}{d t} + L (R_1 + R_2) I_1 = I_m (L_2 R - R_2 L) e^{-\frac{R}{L} t} + I_m R_2 L \qquad (8)$$

Solving for I_1:

$$I_1 = \left[\frac{I_m (L_2 R - R_2 L)}{L (R_1 + R_2) - R (L_1 + L_2)} \right] e^{-\frac{R}{L} t} + \frac{I_m R_2}{R_1 + R_2} + c\, e^{-\left(\frac{R_1 + R_2}{L_1 + L_2} t\right)}$$

Substituting the value of c, when at $t = 0$, $I_1 = 0$:

$$I_1 = \left[\frac{I_m (L_2 R - R_2 L)}{L (R_1 + R_2) - R (L_1 + L_2)}\right] \left[e^{-\frac{R}{L} t} - e^{-\frac{R_1 + R_2}{L_1 + L_2} t}\right] + \frac{I_m R_2}{R_1 + R_2} \left[1 - e^{-\frac{R_1 + R_2}{L_1 + L_2} t}\right]$$

The time of maximum I_1 can be found from the relation:

$$\frac{d I_1}{d t} = I_m \left(\frac{R_1 + R_2}{L_1 + L_2}\right) \left(\frac{L_2 R - R_2 L}{L(R_1 + R_2) - R(L_1 + L_2)}\right) e^{-\frac{R_1 + R_2}{L_1 + L_2} t} - I_m \left(\frac{R}{L}\right) \left(\frac{L_2 R - R_2 L}{L (R_1 + R_2) - R (L_1 + L_2)}\right) e^{-\frac{R}{L} t} + \frac{I_m R_2}{L_1 + L_2} e^{-\frac{R_1 + R_2}{L_1 + L_2} t} = 0$$

Or:

$$t = 2.3026 \left(\frac{L (L_1 + L_2)}{R (L_1 + L_2) - L (R_1 + R_2)}\right) \log_{10} \frac{(L_1 + L_2)(L_2 R - R_2 L)}{L (R_1 L_2 - R_2 L_1)}$$

The curves of Fig. 6 were calculated in this manner.

Transient Currents During Short Circuits and Under Normal Loads

The ratio of inductance to resistance of the usual railway circuit fed by a given circuit breaker involving the motors of cars or locomotives under maximum normal load conditions is usually considerably higher than that of the feeder circuit alone when a short circuit occurs at the maximum distance from the circuit breaker. A typical comparison is shown by the curves of Fig. 3. By taking advantage of this difference the magnetic type of high-speed circuit breaker can be equipped with an inductive shunt proportioned to trip the breaker at current values considerably lower than the steady load setting with a short circuit through the maximum length of feeder without danger of too frequent operation by transient currents encountered under normal load conditions.

In addition, the mechanical speed at which the magnetic type of circuit breaker opens after the trip point is reached is affected, to some extent, by the amount the trip coil current is increased in excess of that required for tripping the breaker. The force for accelerating the contact arm of the circuit breaker is the difference between the tension of the main springs and the holding effect of the armature flux. As the current

through the tripping coil is increased, a greater resultant force is available for accelerating the contact arm mechanically. The curve of Fig. 4 shows this relation between the force available for accelerating the contact arm and the current through the trip coil.

The inductive shunt in multiple with the trip coil is, therefore, not only effective in reducing the trip point

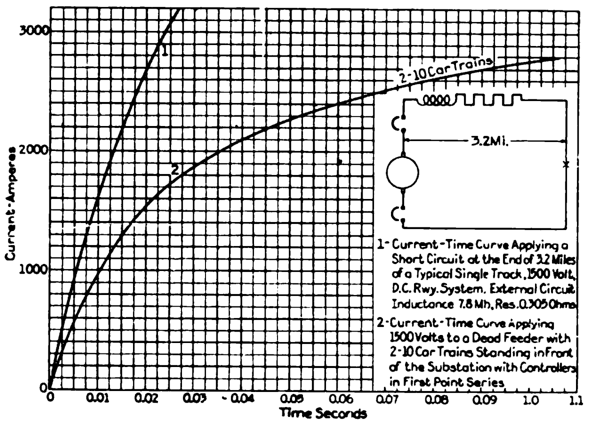

Fig. 3—Curves Showing the Difference in Rate of Current Rise Caused by Applying a Short Circuit at the Distant End of a Feeder and Energizing a Dead Feeder with Load in the Other Substation

of the circuit breaker under short circuit conditions, but is also effective in forcing a greater percentage of the line current through the trip coil after the trip point is reached with a consequent greater mechanical speed of operation of the circuit breaker under conditions where selective operation is desired.

A breaker of this type can be made to operate fast enough, in many instances, to limit the maximum current during a short circuit to a value below the normal overload setting. Such a breaker will "discriminate"

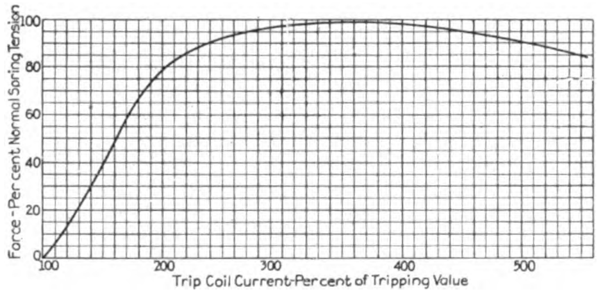

Fig. 4—Resultant Force for Accelerating Contact Arm of the Magnetic Type of High-Speed Circuit Breaker

between normal overloads and short circuits, and this characteristic is frequently referred to as the discriminating characteristic of the circuit breaker. The amount of discrimination is limited only by the transient currents, encountered under normal load conditions.

This discriminating characteristic contributes greatly to the selective operation between breakers, both in substations and in the complete feeder network.

Selective Operation Between Feeder and Machine Breakers

For selective operation in the substation, it is the practise to equip the feeder breakers with inductive shunts which impart a decided discriminating characteristic. The high-speed breakers for machine protection have no discriminating characteristic; that is, their trip point is independent of the rate at which the current is rising. A short circuit on the feeder of a substation so equipped, in most cases, will be cleared by the feeder breaker without tripping the machine breakers and interrupting power to the station bus and other feeders. This statement applies for a majority of short circuits where only one machine is operating in the substation and both machine and feeder breakers carry the same short-circuit current because of the reduction in trip point and faster operation of the feeder breaker.

Where the total machine capacity connected to the station bus is considerably in excess of the capacity of the feeder as is usually the case during important traffic periods of the large systems, short circuits within several hundred feet of the station on the ordinary feeder will open the feeder breakers without operating the machine breakers.

Selective Operation Between Breakers in the External Network

By examining Fig. 5, the function of the discriminating breaker in the external net work may be better understood.

Nos. 1, 2, 7, and 8 are substation feeder breakers and Nos. 3, 4, 5, and 6 are sectionalizing tie breakers.

Assuming a ground occurring at S on feeder B near

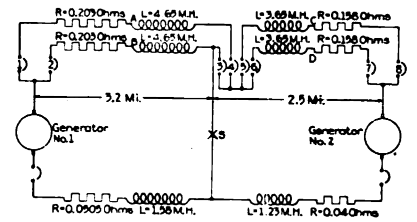

Fig. 5—Equivalent Network for a Typical Double-Track, 1500-Volt, D-C. Railway System, Showing Location of Circuit Breakers

the tie station, the rate of increase of current and the current at any instant through breaker No. 3, due to the short circuit, will be the sum of currents through the three breakers, Nos. 1, 7, and 8. Breaker No. 3 will, therefore, trip at a very much lower value than that required to trip either of the three breakers Nos. 1, 7, or 8, and will operate fast enough to limit the total current to a value considerably below the total required for tripping any of these three breakers feeding the short circuit through the tie station.

The short circuit, under such a condition, will be cleared by breaker No. 3 at the tie station and breaker No. 2 at the substation without interruption of power

to feeders *A*, *C*, or *D*. The discriminating characteristic is effective under these conditions in reducing the trip point and in speeding up the operation of breaker No. 3 so that the short-circuit current is limited to a value considerably below that necessary for tripping the other feeders.

It also reduces the trip point of breaker No. 2 sufficiently to operate it even though the resistance of the feeder limits the current to a value below the steady overload setting.

It can be stated in general that as the number of feeders interconnected through a tie station is increased, the selective operation between the breakers feeding a short circuit directly and the breakers feeding interconnected feeders is more easily obtained. This may be explained as follows: With a certain number of interconnected feeders, when a short circuit occurs on one feeder a certain proportion of the current on this feeder will flow from each other feeder. With a larger number of interconnected feeders the current in this feeder will be larger in proportion to the current in each of the other feeders. Also the current in this feeder will more quickly rise to the tripping point of this feeder's breaker. And this in effect means that the selective action of the system increases when the number of feeders is increased.

III. Reduction in Trip Point with Reduced Line Voltage

The holding coil of the magnetic type of high-speed breaker can be excited from the main feeder circuit when desired. When so connected, the trip point is a function of the line voltage. When breakers having their holding coils so excited are connected in the feeder network at some distance from the substation during a short circuit, the trip point of any breaker will depend on its distance from the fault, the nearest breaker having the lowest trip point. Breakers which are identical in every respect, connected in the same feeder at some distance from each other and subjected to the same short-circuit current, can be operated selectively in this manner in such a way that only the breakers adjacent to the fault open.

Under such conditions when a short circuit occurs at a sufficient distance from the substation to include a sectionalizing breaker, such as on a feeder near the sectionalizing tie station of Fig. 5, the current rise is sufficiently slow to allow time for the desired change in the holding-coil current and results in the operation of the tie breaker before the short-circuit current reaches the trip point of a similar breaker near the station, the holding-coil current of which is not appreciably affected by the short circuit.

The curves of Fig. 6 may be taken as typical and apply to the system shown by Fig. 5 with a short circuit on feeder *A*, with power fed from station No. 1 only, breakers No. 1, 2, 3, and 4 only closed.

The rate at which the holding current is reduced under such conditions is easily controlled by regulating the time constant of the holding-coil circuit, and by choosing the portion of the saturation curve of the holding-coil magnetic circuit over which the breaker operates under normal conditions. The breaker can be designed with a highly saturated holding magnetic circuit, so that the trip point is not greatly affected by voltage reductions occurring in normal service, but will have its trip point lowered very rapidly by voltage reductions in excess of a predetermined maximum.

In general, exciting the holding coils from the line does not place objectionable limitations on the transfer of power through a tie station. Referring again to Fig. 5, this point may be illustrated by the following limiting cases:

(1) With a tie station at the extreme end of a double-

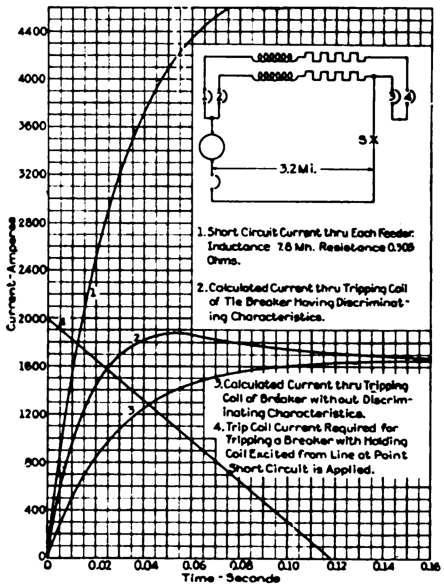

Fig. 6—Current-Time Curves Applying a Short Circuit Opposite a Sectionalizing Tie-Station 3.2 Mi. from Substation on a Double-Track System with Stub-End Feed. Breakers No. 2 and No. 3 Tripped

track system, stub-end feed, the tie breakers will carry only one-half the load under the worst conditions when the load is all on one feeder.

(2) On a large system with many feeders interconnected through a tie station, an excessive load on any one feeder will not greatly reduce the voltage at this point because of the large number of feeders in multiple.

(3) Where heavy loads occur on all feeders near a tie station simultaneously—a condition which results in the greatest voltage reduction—the exchange in current through the tie breakers will be small and the reduction in trip point will not be objectionable. The effects of reduction of voltage at the tie station under normal conditions on the trip points of breakers the holding coils of which are excited from the line is therefore of no great importance for the usual applications.

Protection of Extremely Long Feeders

In addition to the selective possibilities of such an arrangement when applied to large network, reduction in trip point with reduction in line voltage is useful for applications involving unusually long feeders where short circuits at the extreme distance from the station may result in a current rise and a final current no greater or even less than that encountered under normal load conditions. If such a feeder is sectionalized at some distance from the station by a high-speed breaker with holding coil excited from the line, the trip point will be lowered sufficiently to operate on short circuits at the extreme end of the line, thereby preventing annealing of feeder copper or other damage which might otherwise occur if the short circuit is allowed to persist.

IV. Polarized Characteristics

The direction of current required for tripping the magnetic type of breaker is fixed by the polarity of its holding coil.

Referring again to Fig. 5, all of the holding coils of the sectionalizing tie breakers 3, 4, 5, and 6 are excited from the station bus. The polarity of these breakers is fixed so that they trip on current flow from the tie bus to the feeder only. A short circuit occurring in the vicinity of the sectionalizing tie station, such as at *S*, reduces the trip point of all breakers located at this point. The direction of the short-circuit current is correct to trip No. 3 breaker, but assists in holding in breakers 4, 5, and 6. The short circuit under such conditions will, therefore, be cleared by breaker No. 3 without having interrupted the tie between feeders *A*, *C*, and *D*. The polarized characteristic is, therefore, of great assistance in preventing the operation of the breakers feeding power to the tie bus.

Tests on Equivalent Network

A series of tests was made on the equivalent network of Fig. 5 to demonstrate the selective possibilities of the magnetic type of high speed circuit breaker on a representative system.

For approximately uniform spacing between substations and sectionalizing tie stations, selective operation is more easily obtained on networks of the general form of Fig. 5 as the number of tracks and feeders increase. The transient current through that section of the individual feeders between the substation and the fault is not greatly affected by the number of parallel feeders, and the performance of station feeder breakers clearing short circuits on the feeder to which they are connected is therefore not affected. At the sectionalizing tie station the ratio of current rise in the breaker feeding the short circuit direct to the current rise in the several feeders feeding the short through the tie station is increased as the number of feeders is increased, this greater difference resulting in more positive selective operation.

The section of double-track system, the equivalent circuit for which is shown on Fig. 5, was, therefore, taken as representative of the more difficult type of system for selective operation and was used for the experimental investigation.

Equivalent circuits were set up for each feeder using cast-iron resistors and air-core inductance coils.

While both mutual and self-inductance of the parallel copper conductors comprising each feeder of network are easily calculated, calculations of inductance of the rails of the track return are difficult because of skin effect and variations in magnetic permeability.

The values on which the calculations for the equivalent network were based were taken from the data obtained during a series of short circuit tests on an actual system involving a rate of increase of current of the same order of magnitude as that of the equivalent system. The method consisted in calculating the inductance of the copper conductors of the feeder on which the tests were made and determining the inductance of conductors which at the rail locations gave a total inductance equal to that shown by initial current rise.

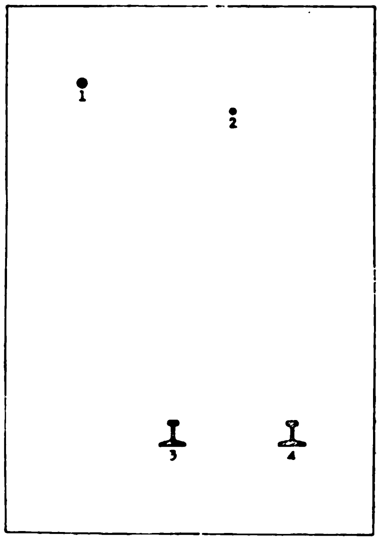

Fig. 7—Cross Section of a Feeder, Trolley Wire and Rails Identified for Calculating the Rate of Current Rise

Air-core inductance coils were necessarily used to represent the total inductance of the positive and negative sections of the feeders.

The self-inductance of these coils was adjusted to give a counter e. m. f. of inductance on the initial current rise equivalent to the total calculated induced voltage of the complete feeder with the same current rise. This voltage is generated both by the self-inductance of the conductors and by the mutual inductance from the other conductors.

The rate at which the current increases in each conductor was determined by solving the following simultaneous equations.

Referring to Fig. 7, in which the conductors are given

numbers that are used as subscripts in the following equations, let E = voltage, L = self inductance indefinite radius, M = mutual inductance:

$$L_1 \frac{dI_1}{dt} \pm M_{1-2} \frac{dI_2}{dt} \pm M_{1-3} \frac{dI_3}{dt} \pm M_{1-4} \frac{dI_4}{dt}$$

$$= L_2 \frac{dI_2}{dt} \pm M_{2-1} \frac{dI}{dt} \pm M_{2-3} \frac{dI_3}{dt} \pm M_{2-4} \frac{dI_4}{dt} \quad (1)$$

$$L_3 \frac{dI_3}{dt} \pm M_{3-1} \frac{dI_1}{dt} \pm M_{3-2} \frac{dI_2}{dt} \pm M_{3-4} \frac{dI_4}{dt}$$

$$= L_4 \frac{dI_4}{dt} \pm M_{4-1} \frac{dI_1}{dt} \pm M_{4-2} \frac{dI_2}{dt} \pm M_{4-3} \frac{dI_3}{dt} \quad (2)$$

$$E = L_2 \frac{dI_2}{dt} \pm M_{2-1} \frac{dI_1}{dt} \pm M_{2-3} \frac{dI_3}{dt} \pm M_{2-4} \frac{dI_4}{dt}$$

$$+ L_4 \frac{dI_4}{dt} \pm M_{4-1} \frac{dI_1}{dt} \pm M_{4-2} \frac{dI_2}{dt} \pm M_{4-3} \frac{dI_3}{dt} \quad (3)$$

$$\frac{dI_1}{dt} + \frac{dI_2}{dt} = \frac{dI_3}{dt} + \frac{dI_4}{dt} \quad (4)$$

The inductive voltage in the positive and negative conductors is then calculated and the air-core coils adjusted for an equal voltage during the initial current rise.

The equivalent circuit involving air-core inductance and cast-iron resistors approximates the actual circuit only because, in the actual system, the time constants of the individual parallel conductors are not exactly the same and as a result the voltage induced by the flux of mutual inductances varies as the current increases. The rate of change of current $\frac{di}{dt}$ decreases more rapidly in those conductors having a relatively high resistance than in those of lower resistance. This is apparent since the voltage for increasing the current is

$$E_L = E - RI \pm M_1 \frac{dI_1}{dt} \pm M_2 \frac{dI_2}{dt}$$

The mutual inductance (M) is relatively small. E = voltage applied to any conductor and I = current.

The error introduced by the approximate method of using the self-inductance of air-core coils to represent the total inductance of the feeder is well within the limits of accuracy of calibration of commercial breakers for the circuit in question.

Separate calculations for each location of the short circuits were made because of differences in magnitude and direction of the mutual inductance effects with short circuits at different locations. The air-core inductances were adjusted accordingly for each test. The values given on Fig. 5 apply for short circuit at the tie station and were modified slightly for short circuits at other locations.

During the tests the holding coils of substation feeder breakers were excited from an independent constant potential source while sectionalizing tie breakers were excited from the line.

The resistance of the individual feeder of this network

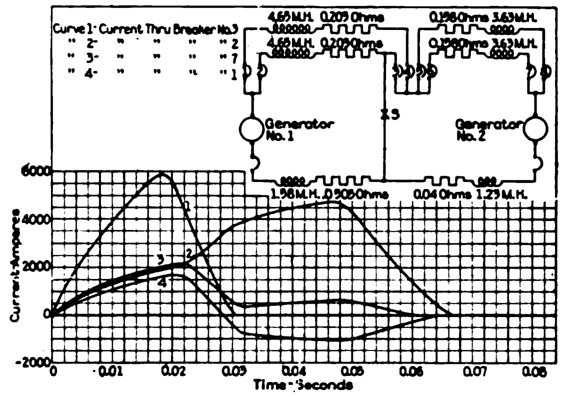

Fig. 8—Current Through Various Breakers During Short Circuit on Feeder Near the Tie Station of Typical Double-Track, 1500-Volt, D-C. Railway System. Breakers Nos. 2 and 3 Tripped

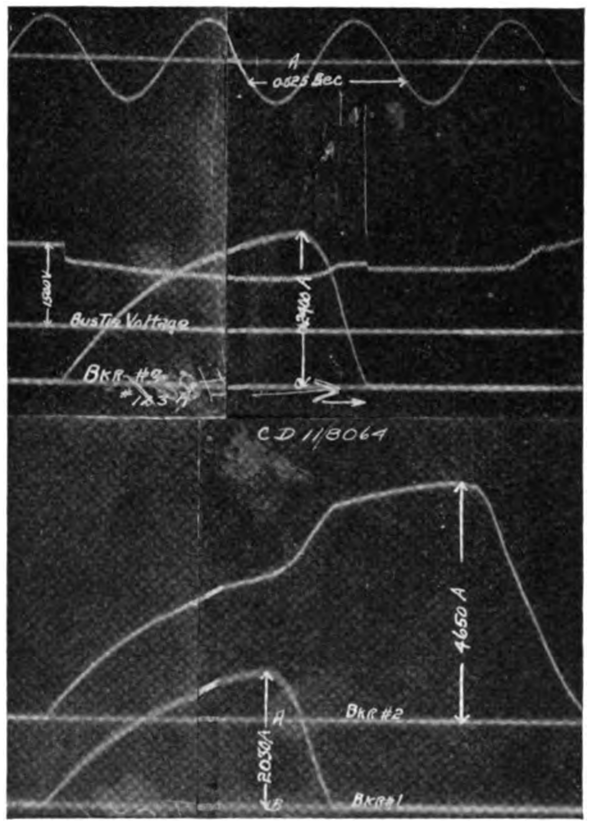

Fig. 9—Oscillogram Obtained when Applying a Short Circuit to the Equivalent Circuit of a 1500-Volt, Double-Track System, Stub-End Feed at the Maximum Distance from the Substation. Short Applied at S, Fig. 5, with Substation No. 1 Supplying Power; Breaker No. 4 Closed. Breakers Nos. 2 and 3 Opened by the Short Circuit

is such that the maximum current through each feeder with a short circuit at the sectionalizing tie station is less than the normal load setting required (6000

amperes). The maximum load condition in the individual feeders on a single breaker determined from the train schedules is encountered when restoring power to a dead feeder on which two ten-car trains are standing immediately in front of the substation with their controls in the first point series. The transient currents for these two limiting conditions are shown by the curve of Fig. 3. The current rise when closing the circuit of the two ten-car trains with the control in the first point was interpolated from oscillograms obtained during a series of tests made on a 600-volt system.

Breakers having identical constants were selected for

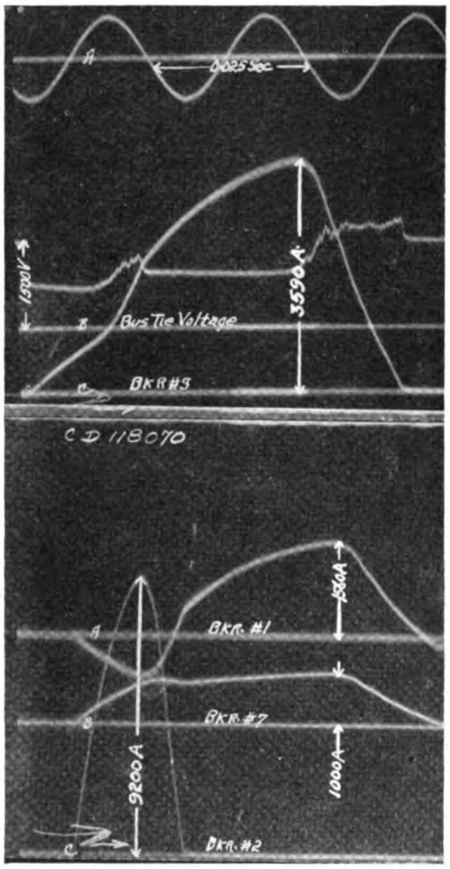

Fig. 10—Oscillograms Obtained when Applying a Short Circuit to the Equivalent Network Shown in Fig. 5. Directly in Front of Substation No. 1 on Feeder *B*, with All Breakers Closed. Breakers Nos. 2 and 3 Opened by the Short Circuit

all locations on the experimental network. The sectionalizing tie breakers were duplicates of the substation feeder breakers with the exception that their holding coils were excited from the feeders, the holding coils of substation feeder breakers being excited from an exciter bus.

A 1500-kw., 1500-volt generator was used as a power supply for each substation. All breakers were set for a steady overload of 6000 amperes. Selective operation completely isolating the faulty feeders without interrupting power supply to interconnected feeders was obtained for all locations of short circuits applied to the experimental network during the series of tests.

Referring again to Fig. 5, the most important locations tested were as follows:

1. Short circuits on all feeders both directly in front of substations and the sectionalizing tie station,

2. Short circuit on feeder *B* at the tie station while carrying a 2000-ampere load in the center of feeder *D*,

3. Short circuits one-half way between substations and tie stations,

4. Short circuit at the substation and at the tie station with a stub-end feed from a substation to the tie station.

The curves of Fig. 8 were taken from oscillograms of a short circuit at *S* of Fig. 5. Several of the actual oscillograms are shown on Figs. 9 and 10. It is interesting to note that as the short is disconnected from the the tie bus the current increases rapidly through breaker No. 2 speeding up its operation.

While it was not possible to simulate all of the conditions of load and short circuits encountered during the operation of such a system, the results of the tests indicate that it is possible to obtain a high degree of selective operation on d-c. railway feeders by the proper utilization of the inherent characteristics of the magnetic type of high-speed circuit breakers.

Several important installations involving a complete equipment of high-speed breakers designed for selective operation based on the principles discussed in this article have been made in the last few years.

The High-Speed Circuit Breaker In A-C. Railway Network

The discussion in the preceding paragraphs of this article has been confined to the d-c. railway network. A method of operation has recently been developed whereby the same type of high-speed breakers applied successfully to the d-c. railway system for a number of years may be applied to the a-c. network.

By the proper application of a-c. breakers of this type many of the advantages of high-speed protection can be realized on a-c. railway feeder networks. The duration of short circuits and resultant damage to apparatus, particularly in case of an arc, can be limited to a small percentage of that resulting under similar conditions with the usual slow-speed protective apparatus. High-speed protection is also of particular value in eliminating telephone interference during a-c. short circuits.

Furthermore, by taking advantage of the characteristics of the magnetic type of high-speed breaker, a high degree of selective operation can be obtained on a-c. circuits, isolating short circuits in a fraction of the time required with the usual type of protective system involving slow-speed breaker, inverse time relays, pilot wires, and the like.

The Effect of Internal Vacua
Upon the Operation of High-Voltage Cables

BY WILLIAM A. DEL MAR[1]
Fellow, A. I. E. E.

***Synopsis.**—It has been known for some time that the internal mechanical pressure of cables is a factor in the quality of the insulation, and that the oil used in impregnating paper for cable insulation has a high thermal expansion which may alter the internal pressure of cables with varying temperature.*

This paper considers the rate of pressure equalization in cables and the relative effects of slow equalization upon long and short cables, indicating that there may be considerable difference in dielectric properties depending on the length and past history in regard to temperature cycles.

Means of overcoming these differences are suggested.

The paper is suggestive rather than demonstrative and it is proposed to publish a sequel giving experimental proofs of the facts stated.

CABLE failures have often occurred which have not been explained to the satisfaction of both manufacturing and operating companies. Their outstanding feature from the manufacturers' standpoint has been the fact that individual lengths of cable withstand severe and prolonged high-voltage tests sometimes extending over a week or more, even after removal from the ducts, but when joined into a long cable, they have been, nevertheless, unable to operate at their normal voltage.

This has naturally led to the belief on the part of the manufacturers that in operation the cables must be subjected to more destructive potentials than they experience in the tests, or in other words, that the trouble is due to transient high voltages.

The only alternative is that, in some way, the joining together of a number of dielectrically strong lengths can result in a dielectrically weak cable.

Until recently, this latter alternative seemed scarcely worth consideration since it was outside the range of reasonable probability, whereas the theory of transients seemed to have some foundation in actual circumstances such as the concentration of failures at certain points, regardless of time or place of manufacture of the cable.[2]

The point of view of the user usually seems to have been that the actual evidences of severe over-voltage are negative, whatever the theoretical evidences in their favor might be. They have discounted the proofs of excellence of the individual lengths of cable, and explained the failures on the assumption that the cables are either impregnated with chemically unstable oil or that the cable is incompletely impregnated, the evidences of which are likely to be found in the cables that fail. This theory has not satisfied the manufacturers because cables impregnated with identical compound have been known to operate satisfactorily at higher electric stresses than those in the cables that failed. The manufacturers agree that practically perfect impregnation is essential to obtaining high dielectric strength but have not considered deficiencies in the impregnation or unstable oil to have been always the root of the trouble.

New information has now come to light, however, which explains how a number of good lengths of cable can be joined together into a bad cable, and the evidence is stronger than that which has been adduced in favor of the theories of abnormal voltage, or of defective cable.

The difference between the short length and the continuous cable, as manufactured in the past, is that the former has its ends open to the atmosphere so that the inside of the cable is at atmospheric pressure, whereas the latter, except near its ends, has an internal pressure independent of that of the atmosphere, by virtue of the continuity of the sheaths and joint sleeves, and the viscosity of the compound.[3]

On this difference, in our opinion, hangs the explanation of many mysterious cable failures.

Causes of Vacua in Cables

Oils, such as are used for impregnation, have an extraordinarily high coefficient of thermal expansion, usually of the order of 0.09 to 0.1 per cent by volume, per deg. cent. This is about ten times that of the metals used in a cable. In order to visualize the effect of this, we may assume that all of this change in volume is concentrated at one end of the cable, and consider what happens when a length of, say, 400 ft. is cooled. If the cable is completely filled when it leaves the factory, which may be assumed to be at about 25 deg. cent., and is then put in a duct at 0 deg. cent., the volume of oil will have shrunk 2.5 per cent so that 10 ft. of the cable will be completely deprived of oil.

In actual fact, this shrinkage will not be concentrated at one place but it will be none the less real and, in the aggregate, will be equivalent to the 10 ft. of cable. Where the distance from the center of a cable to its open ends is several miles the time required for internal readjustment of pressure, with heavy petrolatum compound, may be several years, especially if the

---

1. Chief Engineer, Habirshaw Cable and Wire Corporation.

2. There is no doubt that transients have been a contributory cause of trouble, especially on large systems.

3. Cable compounds being very viscous, flow slowly, so that in the case of a petrolatum-impregnated cable, the readjustment of internal pressure is necessarily a very slow process, varying from practically zero speed with hard compounds and solid conductors to practically infinite speed with thin liquid compounds and hollow conductors.

Presented at the Regional Meeting of District No. 5, of the A. I. E. E., Madison, Wis., May 6-7, 1926.

cable is lightly loaded. It is thus a matter of vital importance to load high-voltage cables, when impregnated with stiff compound, either prior to or upon the application of the voltage, and to maintain a load sufficient to liquefy the compound until internal pressures have been adjusted.

The contraction of compound in a cable is very beautifully shown by impregnating a piece of cable in a light-colored oil, and transferring it while hot to a dark-colored oil in which it is allowed to cool. The outside of the cable will be the first to lose its heat and the oil will, therefore, solidify there first. Hence, as the oil contracts, it will draw away from the center.[4] The dark grease used for cooling will, however, be sucked into the hollow so that the cable in cross section will present the appearance of a hollow ring of light color with a dark core. A small amount of dark compound will also be found in the outer layers due to diffusion. If the cable were allowed to cool in the open air, instead of in dark oil, the core would be free of oil except for that held in the paper by capillarity. Other vacuous spots will form in the compound as it contracts, either as bubbles or streaks.

Lead, which is used universally for cable sheaths, is peculiar in being almost entirely lacking in elasticity; that is to say, when it is stretched, it does not return upon removal of the stretching force. When a cable is put on a reel at the factory, its sheath is stretched on one side, and when the cable is straightened, to go into a duct, the stretched sheath does not contract, but wrinkles, thereby increasing the internal volume. The amount of this increase may, under favorable conditions, be as high as ½ per cent, so that in a case where the oil constitutes ⅓ the cubic contents, the increased volume would take oil from about 1½ per cent of the cable, an amount of similar order of magnitude to the disappearance of oil due to contraction.

Thus, there are two causes of vacua in cables which are of somewhat similar order of magnitude, both operating simultaneously and of such magnitude they might desaturate a 400-ft. length of cable to the extent of leaving the equivalent of 15 ft. of cable without oil and with a vacuum in its place. Thus, a petrolatum-impregnated cable having atmospheric pressure at 25 deg. cent. when reduced to 0 deg. cent. shows an internal vacuum of 22 or 23 in., as measured by a pressure gage attached to one end. In this condition, ionization will occur at about ⅓ the voltage which would be required at atmospheric pressure.

It is not only in theory or laboratory tests that this phenomenon occurs. The lead sleeves of a large number of splices on high-tension lines have been known to collapse, proving the existence of very low pressure within the cable. Vacua of 15 to 20 in. have been noted in splices of installed cables, and in such vacua, ionization starts at 40 to 60 per cent of the voltage required at atmospheric pressure.

When high-tension cables are installed, it has been frequently observed that air is sucked in when the caps are broken. This absorption of air continues for hours at a diminishing rate. If the joints are applied before the completion of this action, the cable will necessarily start its working career with a partial vacuum.[5]

Harmful Effect of Vacua

Having shown that vacua should exist in cables and then that they do exist, the next question is, do they do any harm?

Again the answer is in the affirmative.

Partial vacua ionize at much lower voltages than air at atmospheric pressure. Hence, a cable, having a partial vacuum within it, will show evidences of ionization at abnormally low voltages, so that ionization may occur even at working voltage or less.

The effect is not a mere corona glow, but a series of active streamer discharges, such as are familiar to us in vacuum tube lamps. These streamers emit rays, probably the ultra-violet, which have the effect of converting petrolatum compound into a solid, flaky substance, often known as *wax* or *X*.[6] Recent analyses have indicated that this substance has the approximate chemical composition,

$$(C_{12}\,H_{28}\,O)_n$$

It is apparently highly polymerized but of unknown degree of polymerization.[7] It is not a wax.

If petrolatum be placed in a vacuum tube so as to be out of the way of the terminals, but yet impinged upon by the discharge, the surface will be converted into *X*. This interesting laboratory experiment, due to Mr. E. C. Willman, of Cleveland, enables one to see, in process, the phenomenon which is known in cables only by its results.[8] It has been persistently denied by the manufacturers that the presence of this *X* is necessarily an indication of imminent failure of a cable and they are supported in this contention by tests on short lengths which continue in operation at very high stresses even after the practically complete conversion of the

4. The same phenomenon may be observed by heating a small beaker of grease to the melting point and allowing it to congeal. When solid, the surface will be funnel-shaped instead of practically flat as when water congeals.

5. A collapsible cap filled with compound may be placed over the ends of a cable when the seals are broken, which will prevent access of air and fill the voids with compound. Such a cap should be left on for several hours, preferably overnight. The use of such caps both in factory and field is the subject of a patent application.

6. Ultra-violet rays have a similar effect upon most oils. In the case of some vegetable oils, the effect is so pronounced that it has been made the basis of a commercial lacquering process.

7. Some experimenters report a very small proportion of nitrogen, but we regard this as too minute to be more than an impurity.

8. It was formerly thought that *X* was due directly to the electric stress, but it has not been found possible to produce it by stress alone, in the absence of electric discharges.

oil into X, yet cable users have known that, in some way, X formation and cable failure go together. These views are reconciled by the fact that short lengths of cable, such as are tested in laboratories by the manufacturers, will not fail due to X because their internal pressure quickly becomes atmospheric whereas long (installed) lengths are more liable to failure because, with stiff compounds, low pressures persist due to the slowness of pressure equalization. Furthermore, X formation increases vacua because X is less bulky than oil, and as mixed with the residual oil it forms a paste which is stiff and resistant to pressure equalization. If conditions are such as to create X, but yet maintain atmospheric pressure, the cable often will not fail.

A number of short lengths (10 ft. under lead) of cable were submitted to an accelerated aging test, one-half the cables being sealed hot, so as to have partial vacua within them when cool, and the other half allowed to cool with the compound at atmospheric pressure. The preliminary results show the vacuous cables have a much shorter life than those at atmospheric pressure, but difficulties in maintaining the seals have vitiated all experiments as far as quantitative results are concerned. The experiments are, therefore, being continued and Mr. C. F. Hanson expects to report them at a later date.

THE WAY TO AVOID HARMFUL VACUA

We have seen the cause of vacua in cable, and their baneful results. The next question is, naturally, how can they be avoided?

Before answering this, it should be borne in mind that an installed cable ordinarily has an internal pressure entirely independent of the atmosphere because its sheath and the sleeves of its joints are sufficiently thick and rigid to resist considerable pressure.[9] In order to maintain the inside of the cable throughout at atmospheric pressure, there must be the equivalent of openings to the atmosphere, compounds sufficiently fluid to transmit the pressure from these openings at a speed comparable with that at which thermal contraction occurs and longitudinal oil ducts of sufficient cross-sectional area to assist this action. In most cases the normal spaces between strands will suffice, but for very high voltages, a hollow core or special duct is desirable.

In order to provide the equivalent of openings in the cable or joint these must either be open to the air, or provided with a closed but collapsible part. The reservoir of liquid or semi-liquid oil applied to splices in an invention first used at Cleveland meets the latter requirements,[10] while the liquid oil reservoir system, developed in Italy, meets the former, although neither appear to have been intended for the specific purpose described above.

It should be remembered that pressure equalization is very slow with viscous oils, and differences of pressure should not be allowed to accumulate, but rather should be given an opportunity to equalize as they are forming.

In conclusion, we summarize the following characteristics as among the most essential for the successful performance of high-voltage cables:

1. The compound should be sufficiently fluid or soft at all operating temperatures to permit readjustment of internal hydrostatic pressure at a speed comparable with that at which this pressure is disturbed by temperature variations.
2. Access to the atmosphere or to atmospheric pressure should be provided at points sufficiently close to ensure the communication of such pressure to all of the compound in the cable.
3. Oil ducts (special or incidental) must be provided to assist the transmission of this pressure along the cable.
4. The saturation of the cable should be as perfect as possible so as to provide a minimum of oxygen to be absorbed by the compound.
5. The compound should be as immune as possible from deterioration by the rays generated by electrical discharges.

In addition to these characteristics, which are related to the subject matter of this paper, the cable should have, of course, suitable dielectric strength, dielectric loss and flexibility.

NEW MACHINE MINES COAL BY ELECTRICITY

A new-type electrically driven mining machine is being now tried out in various coal regions of the country. It is a powerful machine that cuts its way into the face of a bed of coal, breaks the coal loose and loads it into mine cars without the exercise of manual labor or the firing of a single ounce of powder or dynamite, such as often cause mine explosions. In a test run, this machine was able to bore its way into a coal seam at the rate of one foot in ten minutes and at a total mining cost of half that prevailing in the hand-working sections of the same mine. The entry driven in coal by the machine is 6 ft. high and 11 ft. 6 in. wide. —*Soc. of Elec. Dev.* May 30th, 1926.

9. A pressure of 35 to 45 lb. per sq. in. will start expansion of 8 64 to 10 64 in. pure lead cable sheath.

10. The Cleveland reservoirs were designed for the purpose of exerting atmospheric pressure "on the mobile compound to prevent the formation of voids during temperature changes," (Report of Underground Systems Committee, N. E. L. A., 1924) but as only the joint compound was mobile, the cables being impregnated with petrolatum jelly compounds, the reservoir appears to have been intended primarily as a protection for the joint rather than for the cable.

11. Emanueli, *Transactions* of the First World Power Conference, 1924, Vol. III, p. 1269, states: "The possibility of manufacturing cables destined to work at such high pressures (130 kv.) depends on careful reduction to a minimum of the gas which is occluded between successive layers of the insulating material," and *Jour.* I. E. E., Jan. 1926, p. 127, referring to the 130 kv. cable in Italy, "Its construction differs from that of an ordinary cable only in the fact that air or gas bubbles are entirely eliminated from the insulation."

Rectifier Voltage Control

BY D. C. PRINCE[1]
Fellow, A. I. E. E.

Synopsis.—*Lack of voltage control is one of the objections which have been made to the use of rectifiers. The author describes a method of voltage control for rectifiers based on the use of a saturated core interphase transformer. Saturation of this device produces a gradual change from two three-phase rectifiers operating in parallel to one six-phase rectifier which has a higher inherent voltage ratio. The theory of operation is discussed and supporting oscillograms and observed regulation curves are shown.*

A RECTIFIER is a kind of electric valve which allows current to flow from an alternating supply into a d-c. load circuit. The instantaneous alternating voltage varies all the way from $\sqrt{2}$, the effective value in one direction, to the same amount in the other direction. There is, therefore, nothing startling in the idea that any voltage between these limits can be communicated to the load circuit. The problem is rather one of practicability than of possibility.

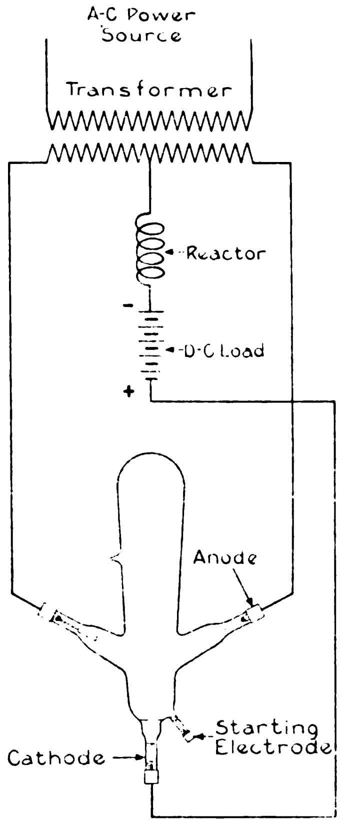

FIG. 1

The voltage communicated to the load circuit is not an instantaneous, alternating value but is an average over a considerable part of a cycle. Consider a simple, single-phase rectifier as shown diagrammatically in Fig. 1. The corresponding wave diagram is shown in Fig. 2. Current flows from the most positive anode to the cathode so that the cathode potential is below the most positive anode only by the amount of the arc drop which is practically constant and relatively negligible in rectifiers having any considerable output voltage.

This diagram assumes no inductance in the transformer or primary supply. The cathode traverses the series of positive lobes of two sine waves displaced 180 electrical deg. This potential is impressed upon the load and d-c. reactor. The counter e. m. f. load chosen will offer no impedance to the alternating components of the irregular cathode voltage. The inductance will offer no impedance to the d-c. component. The voltage wave is thus resolved into its components. The direct component is the average of voltage for a series of half cycles in one direction

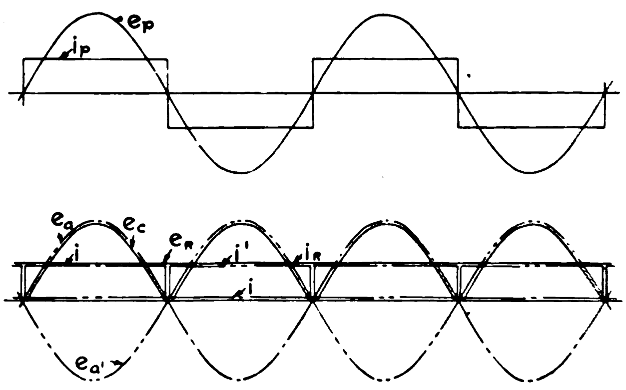

FIG. 2

and is the same as the average of one-half cycle. Its value is $\frac{2\sqrt{2}\,E}{\pi}$ where E is the effective secondary voltage to neutral.

If there were more phases, each anode would be the most positive for a shorter time and so the average voltage impressed on the load circuit would have to be taken for a shorter time. Fig. 3 shows some of the secondaries of a p-phase rectifier. The direction of each coil is the phase vector direction for that phase. For p phases, each anode will be most positive for the fraction of a cycle $\frac{2\pi}{p}$, that is, beginning at an angle $\frac{\pi}{p}$ before the maximum and ending $\frac{\pi}{p}$ after the maximum. The developed voltage wave is shown in Fig. 4.

1. Research Laboratory, General Electric Co., Schenectady, N. Y.

Presented at the Regional Meeting of District No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

The average voltage, G, is found most easily by integrating the wave, that is; finding its area divided by the base.

$$G = \sqrt{2}\,E \times \frac{p}{2\pi}\int_{-\frac{\pi}{p}}^{+\frac{\pi}{p}} \cos\theta \, d\theta$$

$$= \frac{\sqrt{2}\,E\,p}{2\pi}\left[\sin\theta\right]_{-\frac{\pi}{p}}^{+\frac{\pi}{p}} = \sqrt{2}\,E\,\frac{p}{\pi}\sin\frac{\pi}{p} \quad (1)$$

For various numbers of phases, this equation gives the series of values in Table I. It is seen at once that

TABLE I

p	2	3	4	6	∞
G/E	0.90	1.17	1.27	1.35	1.41

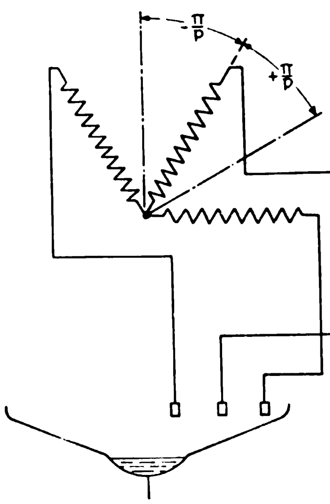

FIG. 3

by increasing the number of phases there results an increase in the average voltage. This indicates how voltage control may be approached. A method of changing smoothly the number of phases from two to

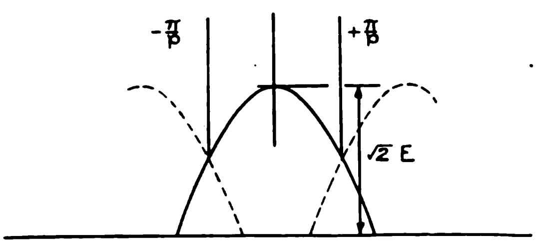

FIG. 4

six would give an increase of fifty per cent in the output voltage.

Two three-phase rectifiers may be connected to a three-phase supply as shown in Fig. 5. These rectifiers have separate inductances in series with their cathodes but feed a common load. Since the two inductances absorb the pulsating components of the voltages of their respective rectifiers, there is nothing to prevent their feeding the load in parallel, each supplying one-half of the current all the time. If the switch S be closed, this condition is changed. There is no longer any impedance to prevent a current shift from one rectifier to the other. Current will naturally flow from the anode with the highest voltage, regardless of its location in a particular rectifier, so that six-phase operation replaces three-phase.

Fig. 6 is a wave diagram of the change. With the

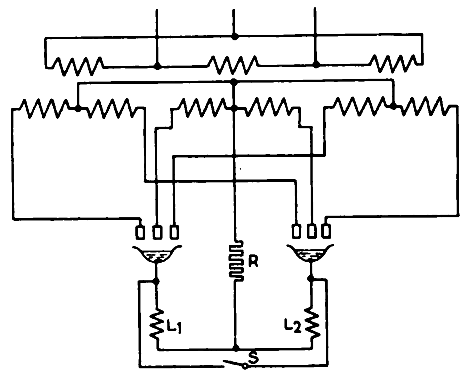

FIG. 5

switch open, the two cathodes have potentials e_1, e_2 averaging e_a. With the switche S closed, the two cathodes follow the potential of the most positive anode, giving the wave e_6 shown by the heavy line.

Instead of the abrupt change from two three-phase rectifiers, the transition might have been made gradually. The two inductances L_1, L_2 may be so interwound that they present large impedance to current changes between rectifiers but low impedance to changes of the total current. The load voltage will then be the average

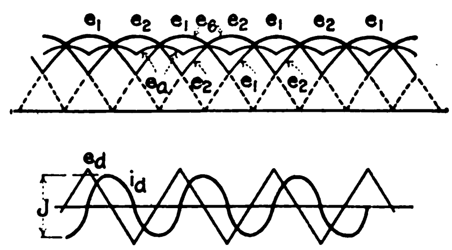

FIG. 6

e_a of the rectifier voltages, but only so long as both are carrying current. Should one stop carrying current, it could no longer influence the average voltage, for both windings of the choke system must carry a variable current in order to supply the inductive drops necessary for the voltage equalizing action.

The inductances, L_1 L_2, are not infinite, so that the tendency of the rectifier having higher voltage to take current from the other will cause a circulating current between the two rectifiers. In Fig. 6, e_d is the difference in voltage, i_d the circulating current. As long as this circulating current is less than the load current supplied by either rectifier, there can always be sufficient current changes to set up the difference voltage and preserve the average. If, however, the interchange

current becomes equal to the load of one rectifier, one will momentarily be carrying all the current, and the voltage will no longer be the average, but will be the voltage of the higher rectifier.

With a further increase in interchange current, there will be a longer period during which there is no drop across the inductances L_1 L_2 and the output potential will follow the higher rectifier for a longer time. Fig. 7 shows the waves under this condition. A value of difference current has been used which has an amplitude equal to the entire rectified current, J. With this

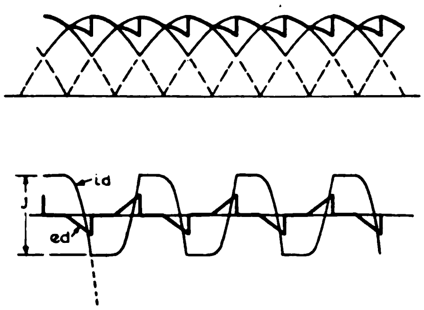

Fig. 7

value, the load current is divided between the two rectifiers half the time and carried by one for half the time. To maintain the difference voltage, the difference current would have had to continue as shown by the dotted extension, but this it could not do because the current from one rectifier could not drop below zero.

Saturation forms a ready means of altering the interchange current as desired. Fig. 8 is a diagrammatic representation of a saturation regulator adapted

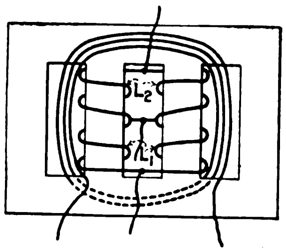

Fig. 8

for this use. It consists of a four-legged core on which two sets of windings are placed. One winding consists of two circuits surrounding the two central legs individually and connected so that the upper and lower halves of each will function as L_2 and L_1, respectively. The flux required for the difference voltage circulates in these two central legs and does not traverse the other two. The second winding used to saturate the core surrounds both central legs. The flux linkages are thus so balanced that current changes in either winding will induce no voltages in the other.

To increase the interchange current which is the exciting current in the central windings a direct current is passed through the outer winding. The flux produced by this current passes in one direction through the central legs and returns through the outer legs. It, therefore, saturates the central legs which carry the alternating flux, and this saturation increases the interchange current and thereby the output voltage.

The direct current required to saturate the core may be obtained from the rectifier output in which case a

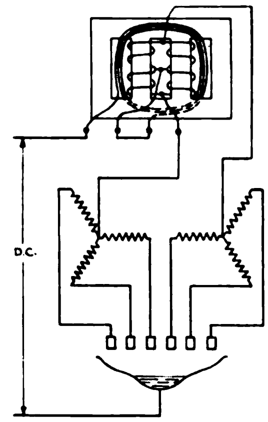

Fig. 9

compound rectifier results, or it may be obtained from a separate source controlled through a voltage regulator. The complete circuit diagram for compounding on load is shown in Fig. 9.

If rectifier transformers and supply lines had no inherent regulation, it would always be possible to secure the increases shown in Table I by changing the equivalent number of phases. There is, however, a considerable amount of regulation in the transformer which tends to be greater with increased numbers of equivalent phases. Take the case of the three-phase rectifier shown diagrammatically in Fig. 10, having all the inductance X concentrated in the anode leads and an infinite choke L to keep the total current constant.

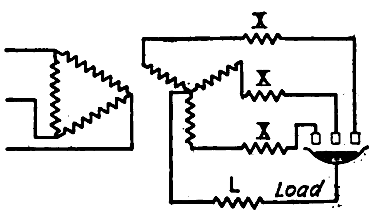

Fig. 10

When the voltages of a_1 and a_2 pass through equality, current will begin to change from a_1 to a_2. While the change is taking place the two anodes are at the same potential since otherwise they would not divide the current. The voltage difference between the two phases is absorbed in the inductances X. The current and voltage appear as shown in Fig. 11.

The rate at which current transfer will take place is proportional to the voltage causing the transfer, which is the vector difference between the phase voltages. At each transfer some of the average voltage

is lost as shown by the crosshatched areas in Fig. 11. The curve of current transfer is a sine wave which lags 90 deg. behind the phase-voltage difference because the drop is inductive. At any instant the value of the rising current to one anode is independent of load because no current change takes place in the load circuit. When all the current has transferred in angle u the

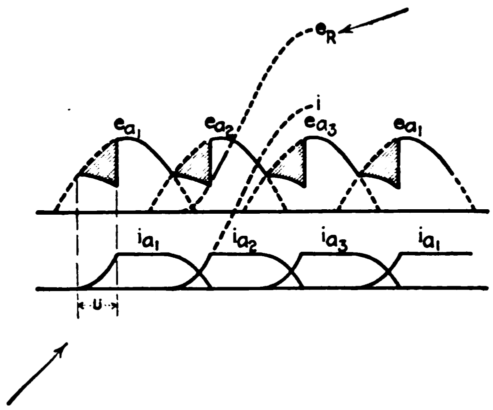

FIG. 11

change ceases. The greater the load, the greater will be the angle u.

It appears from Fig. 12 that the general expression for the phase-difference voltage is

$$\frac{e_d}{2} = \sqrt{2}\, E \sin \frac{\pi}{p} \tag{2}$$

This voltage produces a current

$$i = \frac{\sqrt{2}\; E \;\sin \dfrac{\pi}{p}}{X} \,(1 - \cos \theta)$$

At the end of the lap angle u, the load of direct-current J is reached so that

$$J = \frac{\sqrt{2}\, E}{X} \sin \frac{\pi}{p} \,(1 - \cos u) \tag{3}$$

The curve of instantaneous lost voltage is the same

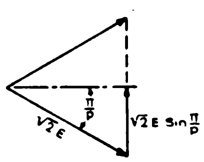

FIG. 12

as the half difference voltage used in making the current transfer. The average loss in output voltage represented by the hatched area is the wave e_R which has the same phase as the current i. Its value is

$$e_R = \frac{p}{2\,\pi} \int_0^u \sqrt{2}\, E \sin \frac{\pi}{p} \sin \theta \, d\,\theta$$

$$= \frac{p}{2\,\pi}\, \sqrt{2}\, E \sin \frac{\pi}{p}\, (1 - \cos u) \tag{4}$$

The open-circuit voltage has already been found to be

$$G_0 = \sqrt{2}\, E \frac{p}{\pi} \sin \frac{\pi}{p} \tag{1'}$$

so that the voltage under load is

$$G = G_0 - e_R$$

$$= \sqrt{2}\, E \frac{p}{\pi} \sin \frac{\pi}{p} \left(1 - \frac{1 - \cos u}{2} \right)$$

$$= G_0 \left(1 - \frac{1 - \cos u}{2} \right)$$

Equation (**3**) connecting J and $(1 - \cos u)$ can be used to replace the latter by the former. This results in

$$G = G_0 \left(1 - \frac{J\, X}{2\, \sqrt{2}\, E \sin \dfrac{\pi}{p}} \right) \tag{5}$$

It would be advantageous to arrange this equation so that the performance of the device might be compared with that of more familiar apparatus. Let it be assumed that there will be a four per cent drop in the transformer when carrying an ordinary sine wave a-c. load equal to its rating for use with a rectifier. Then the short-circuit current per phase is $\dfrac{E}{X}$ or $25 \dfrac{W}{p\,E}$ where W is the rated output of the rectifier.

Equating these two values and solving for X gives

$$X = \frac{p\, E^2}{25\, W}$$

and the output voltage equation may now be written

$$G = G_o \left(1 - \frac{J\, p\, E}{50\, \sqrt{2}\, W \sin \dfrac{\pi}{p}} \right) \tag{6}$$

or making use of equation (**1'**)

$$G = G_0 \left(1 - \frac{\pi\, J\, G_0}{100\;\; W\;\; \sin^2 \dfrac{\pi}{p}} \right) \tag{7}$$

In the derivation of these equations it was assumed that all the reactance was in the secondary windings of the transformer with no mutual reactance. This is convenient and gives results of the right nature. The magnitude of the results may be wrong, however, for, unless all of the leakage reactance is actually located in the manner represented in Fig. 10, the inductance of the paths taken by the commutating currents may be appreciably less than the value obtained by considering short-circuit conditions in the transformer. This is due to the fact that in the latter case the currents have a mutual reaction which can greatly increase the apparent reactance.

The commutating currents on the other hand usually are not required to flow through circuits with much coupling between sections. No advantage of this kind occurs in the single-phase rectifier, but in the three-phase case, the reactance presented to the commutating currents is approximately half that determined by short-circuit measurements. The advantage in the six-phase case is hard to determine exactly. If the transformer

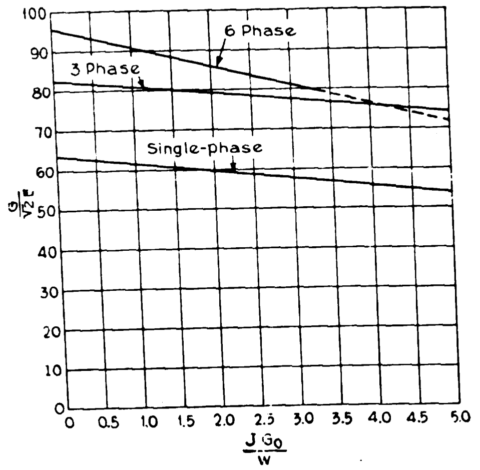

Fig. 13

has a primary and tertiary winding and all the reactance is in the primary, the advantage may be as high as six to one, but as a conservative estimate, let it be assumed that the reactance will be 40 per cent of the value determined from the simple measurements.

Fig. 13 indicates the regulation curves given by equation (7) and takes into account the corrections just described. The regulation curve for the compound rectifier will fall between the curves for the six-phase and three-phase rectifiers. By increasing the saturation of the interphase transformer as the load is increased, it may be made to give high reactance at low loads and small reactance at heavy loads. As a result the output voltage will approach that of a six-phase rectifier under heavy loads and will be nearer to that of a three-phase rectifier under light loads. It will be seen that the range of voltage available for compounding is somewhat limited if only the three and six-phase circuits are used. It is probable, however, that the limits are sufficiently wide for the great majority of applications. A much larger variation can be obtained by going from the single-phase to the six-phase connection. This transition is entirely practical but uses slightly more material than the three-phase to six-phase case and is therefore not desirable as long as the latter arrangement can be made to give the required characteristics.

Under extremely light loads, the direct current through the interphase transformer will be so small that it would be impractical to supply a transformer having sufficient exciting reactance so that its exciting current would always be smaller than the load current. Therefore, the effect of the interphase transformer will be lost as zero load is approached and the no-load voltage will be that corresponding to six-phase operation.

As long as the instantaneous current in the interphase transformer does not fall to zero, its reactance does not appear in the a-c. circuits. As soon as the current in one branch of the interphase transformer is actually interrupted, however, this transformer acts just as though it were inserted in the anode leads. Fig. 14 shows the circuit through which the transient current flows which accomplishes the commutation of the output current between anodes. The exciting inductance of the interphase transformer is added to the leakage reactance of the windings of the main transformer to obtain the value of X used in calculating the regulation curve. The result will therefore be a six-phase regulation curve dropping much more rapidly than that corresponding to the main transformer alone and the rapidity with which the voltage decreases will be dependent upon the exciting reactance of the interphase transformer.

After sufficient load current is flowing so that the interphase transformer is carrying current continuously, the output voltage will be that corresponding to the three-phase rectifier. As more load is applied the output current flowing through the saturating winding of the interphase transformer will decrease the reactance of the main circuit. The exciting current will then rise until it is as large as the load current and continuous choke action will be lost. The voltage will then be displaced from the three-phase value in the direction of the potential corresponding to six-phase operation. By this means the voltage may be held constant over the greater part of the load range or may even be made to increase slightly with load.

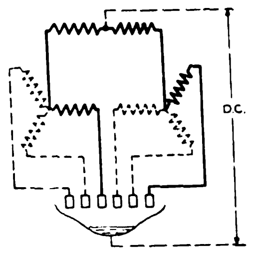

Fig. 14

In Fig. 13 part of the curve for six-phase operation is shown dotted. In this range the voltage is no longer given by equation (7) because the load is so great that three anodes carry current simultaneously during part of the time. Due to lack of complete data on the reactance of the circuits traversed by the commutating currents, it is not worth while to calculate the voltage under these circumstances. The three-phase rectifier curve will have a similar limit of applicability, but this limit is not reached in the range shown in Fig. 13.

Figs. 15, 16, 17 and 18 indicate the results of experimental work which serves as a check on the theory of

operation of rectifiers with compounding. Fig 15 shows the wave shapes obtained with an oscillograph when an experimental rectifier was operating as two separate three-phase units connected in parallel through an un-

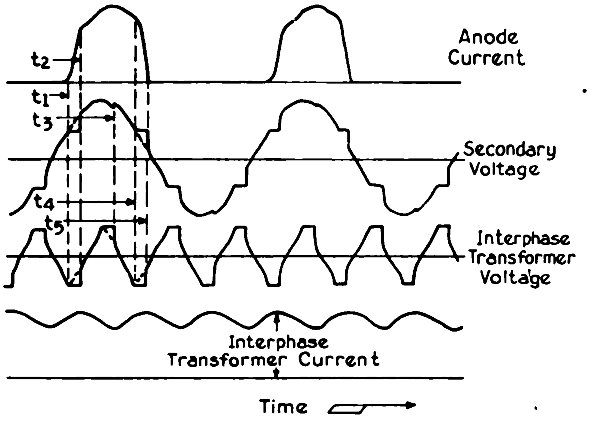

FIG. 15

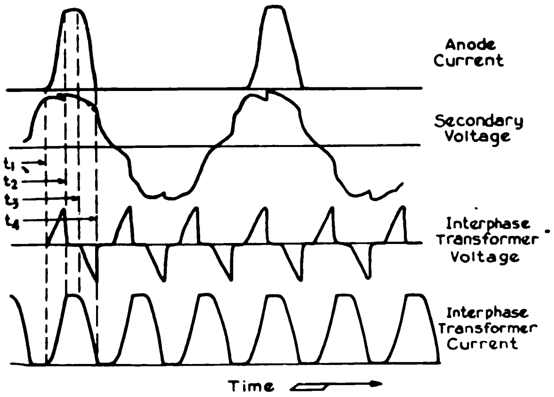

FIG. 16

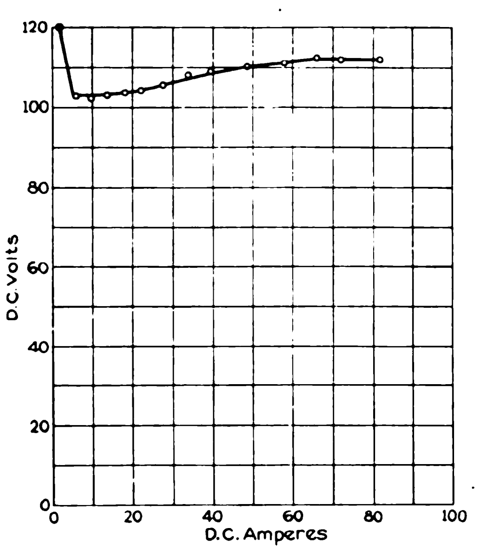

FIG. 17

saturated interphase transformer. At time, t_1, the secondary voltage of the phase being measured became equal to that of the preceding phase in the same three-phase group, and it began to conduct current. Between t_1 and t_2 both phases were conducting current and the reactive drops caused by the changing currents averaged the induced voltages of the two phases so that their terminal voltages were nearly constant. At time, t_2, the current transfer was completed and the terminal

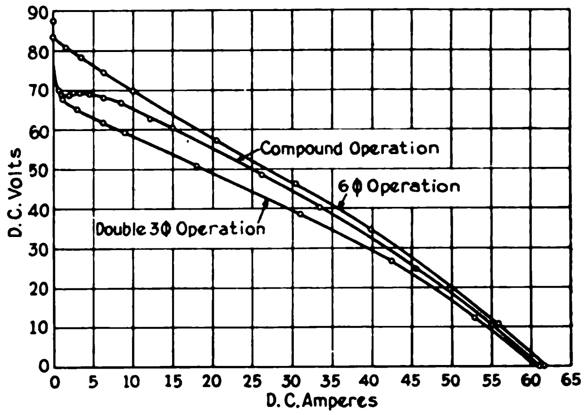

FIG. 18

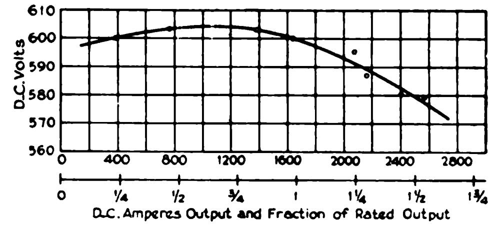

FIG. 19

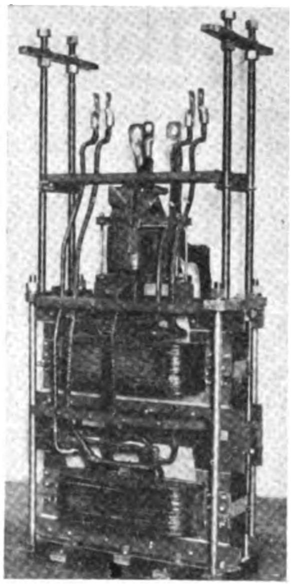

FIG. 20—INTERPHASE TRANSFORMERS

The 180-cycle units are provided with series d-c. saturating coils and variable gap in the d-c. core circuit.

voltage of the incoming phase again became equal to its induced voltage. Between t_4 and t_5, the current left the phase under observation, and this time the reactive drop prevented the terminal voltage of the phase from falling as rapidly as the induced voltage until after the

transfer was completed. The dotted lines indicate the form of the secondary voltage and interphase transformer voltage waves, if they had not been distorted by the reactive voltages during current transfer. The slight irregularity in the secondary voltage wave at time t_3 was caused by commutation of currents in the second three-phase group of windings and was present because of the coupling between the two groups through the transformer primary windings.

Fig. 16 shows the wave shapes obtained with the core of the interphase transformer saturated. The operation is now that of a six-phase rectifier. Current is building up in the phase under observation between t_1 and t_2 and decreasing between t_3 and t_4. Not more than two anodes carry current simultaneously, and between t_2 and t_3 only one anode is conducting. The interphase transformer now carries pulses of current of the same shape as the anode pulses, but, since it carries the current of all the anodes, the pulses will be closer together. There is a voltage across the interphase transformer only during the time the current is transferring between anodes, which transfer must occur through it. As the reactance of the interphase transformer influences the period of commutation, it is apparent that the output voltage can never rise to the six-phase voltage corresponding to the transformer by itself. Instead, the output voltage will approach this value as the reactance of the choke is decreased by saturating it more and more, but can never reach it.

Fig. 17 shows an experimental compounding curve obtained from a small rectifier. After the first sudden drop to the normal three-phase voltage at six amperes, the voltage rises steadily with increase in load to 70 amperes, after which it again falls. To obtain this curve no changes were made other than changes in load. This rectifier had insufficient capacity to stand loading to short circuit. Accordingly, additional reactance was added enabling the curve of Fig. 18 to be taken. In Fig. 18 the load is increased to short circuit under three conditions, with no saturation of the interphase transformer, with the compounding apparatus in operation, and with the interphase transformer short-circuited. Although the compound curve never equals the six-phase curve except at short circuit, the six-phase voltage is approached sufficiently to give flat compounding from light load to 6½ amperes which is 10 per cent of the current under short circuit.

Tests which have been made on the performance of a 1000-kw., 600-volt, 12-phase rectifier further substantiate the correctness of the theories herein set forth. Fig. 19 is a regulation curve obtained with this rectifier adjusted to give substantially flat compounding out to full load, 1667 amperes. Fig. 20 is a photograph of the interphase transformer. Since the set is twelve-phase, there are three interphase units. The two lower units combine each two groups of three phases and have direct current saturating windings. The small top unit combines the two six phase groups into one twelve-phase unit.

Polarization of Radio Waves

BY E. F. W. ALEXANDERSON[1]

Fellow, A. I. E. E.

UNTIL rather recently, the practise of radio communication was confined to the use of long, earth-bound waves. These waves are preferred on account of the regularity of day and night operation and the absence of fading. The characteristics of the earth-bound wave were extensively explored and there was a tendency to generalize these results assuming that they apply to all radio wave transmission.

Usually the earth-bound wave is thought of as a moving electromagnetic field with horizontal magnetic lines sweeping parallel to the earth and vertical electrostatic lines terminating in the conducting earth. This theory has been supported by a great deal of practical evidence. Attempts to measure horizontally electrostatic lines have always given negative results and it almost seemed obvious that this should be so. It, therefore, seemed quite unnecessary to speak of polarization of radio waves, since the waves were supposedly always vertically polarized due to their nature of being earth-bound.

A great amount of data was collected and among these were some surprising observations. For instance, it seemed as if the wave did not always come in from the proper direction but wandered around, seeming to come at times from the side and sometimes even from behind. This led to a good deal of discussion, but no plausible explanation was found. Yet the evidence was accepted as incontrovertible that such direction changes did exist because the observations were confirmed by so many competent observers.

Recent investigations of the phenomena of radio wave propagation, however, have led to another explanation, the conclusion being that the observed irregularities were not actually changes in direction but changes in the plane of polarization. Whether such an explanation had been considered at some earlier date the author does not know, but if it was tentatively advanced, it was undoubtedly discarded on the ground of the experimental evidence, showing that the horizontal electrical lines did not exist. As a matter of fact the

1. Chief Consulting Engineer, Radio Corp. of America and Consulting Engineer, General Electric Co., Schenectady, N. Y.

Presented at the Regional Meeting of Dist. No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

polarization theory did not originate with the study of long-wave phenomena and it requires a new conception of wave propagation, developed through recent work on short waves.

Observations on Short Waves

Our first experience in signaling with horizontally polarized waves was gained as a result of an incident in an investigation which had been organized to study directive radiation with short waves. One of the several directive antenna systems which were used was a combination of two large, square, vertical loops, tuned for a wavelength of 50 m. Each loop consisted of eight sections of conductor, separated by eight condensers so that each section was independently tuned. The composite antenna thus had four vertical conductors, two in each loop, and the object of the test was to regulate the direction and phase of the currents so that the composite antenna would give a unidirectional radiation in the plane of the loops. The only practical way to adjust the phase of the currents proved to be to make measurements of the composite radiation within a few hundred feet of the antenna. When the radiation diagram so obtained was in agreement with the theoretical expectations, it was assumed that the system was properly tuned. The experimental station at Schenectady was in radio communication with the stations of the Radio Corporation of America, at Riverhead, Long Island, and Belfast, Maine, where the signals were measured to ascertain whether the directive characteristics were the same at distant points as near the station. In one case it was found that no radiation whatever could be observed in the field around the station. But investigation showed that, by accident, one of the loops had been reversed so that while current was flowing in all the vertical conductors as indicated by the ammeters, the resultant effect in radiation was zero. No sooner had these facts been ascertained than a communication was received from Long Island that the signals were 50 per cent stronger than in previous tests. In view of the absence of any radiation near the station this surprising result called for further analysis. It was thus found that while the currents in the vertical conductors were in such a direction as to neutralize each other, the two top conductors carried current in the same direction. These conductors being horizontal, it followed that the radiation must have been horizontally polarized and that the failure of the local instrument to indicate any radiation was due to the fact that it was sensitive only to vertical radiation.

Since then, a number of antenna forms for horizontally polarized radiation have been tested and used in commercial service by the Radio Corporation of America. The practical conclusion reached through these tests, as well as the findings of the government laboratories and many amateurs, is that in most cases horizontal transmission and reception with short waves is superior to the old methods of using vertical polarization.

When one attempts to discuss the phenomena of wave polarization, he finds many theoretical and practical aspects and many questions which may be asked. For instance:

How does the wave acquire a horizontal polarization when it is radiated vertically and why does the wave become vertical when it is radiated horizontally?

Does the wave always twist in space or only under some circumstances, and what are these circumstances?

Why is horizontal polarization the rule on short waves and so difficult to discover on long waves?

How strong is static in the horizontal plane?

What relation has polarization to fading?

Does a wave fade in the horizontal and the vertical plane at the same time?

Can direction finders be made to compensate for errors due to polarization?

Many such questions may be asked and only a few can be answered definitely. If the idea of wave polarization is to be more than an empty phrase, we must try to form in our minds a picture of what the wave itself consists before we can intelligently discuss the peculiarities of its behavior.

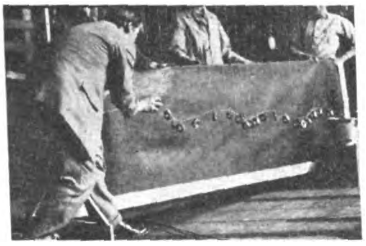
Theory of Wave Motion

This subject is being approached from two angles: One, the classical theory of light radiation in the ether; the other, the electromagnetic theory as we know it in electrical engineering. Both of these theories have their difficulties. The only positive knowledge we have of electricity is the electronic theory. We know that the electron is the smallest element of matter. We know its mass, its electric charge and how fast it travels. But we do not know what magnetism is. As a matter of fact there is good reason to believe that there is no distinct force that can be called a magnetic field. Modern science also denies the existence of ether. We have tentatively substituted a conception of electromagnetic field, in which the energy appears sometimes in electric form and at other times in magnetic form. This is a mathematical rather than a physical substitution, but it is convenient because it permits us to use the equations for the electric and magnetic fields as used in electrical engineering. However, it is not an explanation. To an electrical engineer, a magnetic field is very real and in its nature is quite different from an electrostatic field. From this point of view, it requires a good deal of imagination to conceive that a magnetic field is nothing but a manifestation of a moving electrostatic field. Yet we may be forced to change our conception to that extent. This means the return to Faraday's idea of tubes of force which are material bodies with mass and elasticity.

The ordinary antenna consists of a vertical wire in which electrons periodically move up and down, and the space field, which accompanies the electrons, moves up and down with them. This moving space field is a physical reality. It has a mass and kinetic energy

stored in its motion and it has elasticity. A physical model of such a field can be built. The field itself extends into space but the different portions of the field do not move simultaneously. This elastic, electric body moves in the only way in which one may conceive of a structure maintaining a periodic motion, that is, in waves proceeding from the center. The magnetic field is nothing but the kinetic energy of this moving structure. The electromotive forces which, according to our well-known equations, are induced by the change in the magnetic field, are nothing but the elastic forces which react against the inertia of this electrical body.

With this picture in mind, it is not difficult to see the physical meaning of wave polarization. The ordinary radiator has a vertical conductor in which the electrons move up and down and the accompanying fields move up and down with them within a radius of one-quarter wave length. The inertia of this moving field, close to the conductor, is propagated through an elastic medium in accordance with ordinary laws of wave motion. In the wave which thus proceeds from the origin, every element oscillates in a vertical plane.



Mechanical Model Showing How a Plane Wave Changes Into a Spiral

Thus the vertically polarized radiation is closely analogous to a wave on the surface of water.

The radiator of horizontally polarized waves consists of a closed loop conductor in the horizontal plane. In this conductor the electrons circulate first in one direction and then in the other.

Mechanical Model for Studying Wave Polarization

A mechanical model has been built for the study of wave polarization in the laboratory. The model consists of weights suspended in such a way as to make them free to move in all directions. Twenty-two of these weights are arranged in a row and connected by rubber bands. Each weight is suspended from a yoke and an equal weight hung on the other side of the yoke to serve as a counter weight. A screen is set up so as to hide the counterweights and avoid confusion in observing the wave motion. This model was set up especially to study the twisting of the plane of polarization and the experiment has strikingly confirmed the theory which it was intended to illustrate. This theory is briefly as follows:

Let us assume that the medium through which the radio waves pass has such characteristics that the velocity of propagation for a vertically polarized wave differs slightly from the velocity of the propagation for a horizontally polarized wave. For the present purpose, it is not necessary to try to explain the reason for this difference in velocity, but we may assume that the reason for it is the electrostatic or magnetic earth field or a retarding effect due to the closeness of the earth. Whatever the cause, we may assume that such a difference of velocity exists and the mechanical model has been constructed so as to reproduce such conditions. Thus wave motions in the horizontal or vertical planes can be studied independently, and these two wave motions may be adjusted for different velocities. A wave started in the vertical plane maintains itself vertically and a wave started horizontally maintains itself horizontally. If, however, a wave is started in a plane 45 deg. between the vertical and the horizontal, it is found that the wave motion proceeding therefrom assumes the shape of a spiral. The straight-line oscillation of the first weight is passed along as an elliptical motion which gradually widens into a circle. Then this circle again narrows down to an ellipse and finally to a straight line at right angles to the original line of oscillation. This is exactly in accordance with the theory. The point where the wave has shifted its plane of polarization 90 deg. is the point at which the faster of the two waves is half a wave length ahead of the slower wave. From this point on, the wave proceeds, repeating this peculiar spiral motion.

The fact that the twisting of the wave is due to different velocities in the two planes of polarization can also be demonstrated by this model. For such a purpose, the tension of the rubber bands between the counter weights is changed. The effect of this is to change the velocity of propagation in the vertical plane, whereas the velocity in the horizontal plane has not been affected because only the vertical motion is transmitted to the counter weights by the suspension yokes. The system can thus be adjusted so that the velocities in the horizontal and the vertical planes are exactly equal. After this has been done, it is found that the tendency to spiral motion disappears and the wave remains strictly in the plane in which it has been started.

While this mechanical experiment brings out no new facts unknown to the classical theory of wave motion, it helps us to visualize the main phenomena in the radio wave propagation which we are trying to explain. The phenomenon of a constantly shifting plane of polarization, discovered experimentally in the tests between Schenectady and Long Island, can thus easily be explained.

This conception of the wave motion also is a help in explaining the phenomenon of fading. There is much experimental evidence that fading is a phenomenon of wave interference. In other words, the fading is due to the fact that the radio waves arrive at a certain point through two paths. The waves will sometimes add to each other and sometimes neutralize one another. If

one bears in mind the observations on the mechanical model and the fact that the waves in the two planes can be traced through, separately and distinctly, one may conclude that the two paths of the radio wave which produce fading are not necessarily two separate physical paths but may be the two paths in the horizontal and the vertical plane of polarization. For further illustration of this, a detector may be introduced into the mechanical model. If this detector is placed at a certain distance from the origin it is found that it gives no response when the system is adjusted for different velocities of propagation, whereas when the system is adjusted for equal velocity in the horizontal and vertical plane it gives a maximum response. Thus the phenomenon of fading has been reproduced mechanically through polarization in a single wave path.

By this, it is not suggested that in actual radio transmission the mechanical equivalent is sufficient to explain the fading. However, it is offered for what it may be worth as a help to interpret the many observations in actual radio transmission which are being accumulated.

Irregularities of Direction Finders

It has been known almost since the beginning of transatlantic communication with long waves that measurements of direction of wave propagation with rotating loops show peculiar irregularities from the time of sunset. It has also been known among aviators that direction finder bearings on an airplane are correct only if the plane flies in the line towards the observing station. If the plane flies at right angles, the direction finder gives false orientation as high as 45 deg. or more. This false orientation is greater if the antenna is trailing horizontally. It is therefore attempted to keep the

Transmitting Loops Used in Tests which Revealed Horizontally Polarized Radiation

antenna as nearly vertical as possible by a weight.

A third set of observations has been brought out through the research work in Schenectady on horizontally polarized waves radiated by horizontal loop. Measurements with a direction finder receiver usually give bearings approximately at right angles to the place where the station really is, but sometimes it gives no direction indication at all. Other measurements indicate that the direction of wave propagation is almost perpendicularly vertical. The observation that the wave appears to come straight down from above suggested an explanation that wave components radiated directly upwards had been reflected straight down by the Kennelly-Heaviside layer. However, in view of the other facts to be considered this explanation seems less likely.

Putting all these facts together it seems now that the old observations on the long wave, the airplane, and our recent work on the horizontal loop all may be explained as a characteristic behavior of the horizontally polarized wave. In all three cases, while the wave appears to come in from unexpected directions, it actually does not. When in the third case there is no direction indication whatever, and the wave appears to come in from above, this also is an illusion. The question is, what really does happen?

Transmitting Antenna for Horizontally Polarized Waves and Receiving Instrument Indicating Apparent Wave Direction at Right Angles to True Direction of Propagation

This is the problem on which the experiment with the mechanical model can throw some light. For this purpose let us return to the idea that the radio wave is a mechanical wave motion in the elastic electric medium. In the mechanical model, the weights represent the mass and the rubber bands the elasticity of this medium and the vertical as well as horizontally polarized wave can easily be reproduced. But in order to imitate a wave motion over the surface of the earth, one must also in some way imitate the presence of the earth. The earth is a conductor and therefore the elastic strains represented by the rubber bands cannot exist in the earth. On the other hand, displacement currents in the electric medium can induce conduction currents in the earth. These conduction currents are electrons in motion which can be represented by weights not tied together by rubber bands in the horizontal plane, whereas they are electrically associated with the electric medium above. To imitate this condition, weights may be hung by vertical rubber bands so that they are elastically associated with the wave medium but not connected to each other. If, now, a horizontally polarized wave is sent forth through this system, it is found that the wave motion is propagated to the vertically suspended weights producing elastic strains in the vertical rubber bands. It must be remembered

that the elastic strains represent electromotive forces and these elastic strains so produced are of the same character as if they were a part of a vertically propagated wave motion. No such wave motion actually exists and these strains are only the electromotive forces which induce currents in the ground. If we now assume that a receiving antenna is set up in the form of a vertical loop with its plane at right angles to the wave motion, the primary wave motion does not induce any currents in the loop. However, the secondary electromotive forces, which induce currents in the ground, are in the plane of this loop and tend to induce such currents in the loop. In other words we may say that,

Exploring Antennas

inasmuch as the currents induced in the ground are at right angles to the wave motion, the loop is in the plane of those ground currents which, in their turn, induce currents in the loop.

If this theory is correct, it should be found that false indications of the direction finder and the apparently vertical wave propagation can be observed only in the proximity of the ground. Thus, if observations are made in airplanes high enough from the ground, the horizontally polarized wave should show a horizontal plane of polarization with a true direction of propagation.

Some measurements have been made which confirm these conclusions. By making frequent measurements to within ten miles of the station a set of tests was made exploring the characteristics of a wave radiated from a horizontal loop. The composite picture which was obtained from this test was a continuously twisting plane of polarization with alternate points of plane and circular polarization. At intermediate points, the polarization was elliptical. The plane polarization was indicated by sharp directional bearings and circular polarization was indicated by equal intensity from all directions. The observations indicating plane polarization gave bearings sometimes towards the transmitting station and sometimes at right angles.

Beside these measurements around the vertical axis, observations were made with the loop in the horizontal plane. On flat fields the horizontal position gave nearly zero response. At the top of a steep hill and a high bridge, the response in the horizontal plane was equal to the vertical.

These results indicate the presence of a horizontal and a vertical wave component with different velocity of propagation. Whenever the two waves are in phase, they give plane polarization. When they are 90 deg. out of phase, they give circular polarization. The observation with the loop in the horizontal position on the top of the hill and the bridge shows that even a moderate elevation is sufficient with short waves to reach the point at which the horizontal electromotive forces are not short circuited by the ground.

All this leads the author to believe that horizontal polarization is not confined to short waves only. Direct observation of horizontal polarization at long waves could be made only at great heights but indirect observations through the effect of ground currents can be made by ordinary direction finders at any wave length. If this theory is correct it means that the irregularities of direction finder indications recorded on long waves can be explained by the presence of horizontally-polarized wave components.

JORDAN RIVER TO PRODUCE ELECTRICITY TO REVIVE PALESTINE

The waters of the Jordan River, in Palestine, once were regarded as having power to revive the souls and spirits of men; today the river is helping to revive industry in the Holy Lands. Bernard Flexner, president of the Palestine Economic Corporation, has announced that the new corporation will help finance the hydroelectric station on the Jordan which will supplement the electric power produced by oil-engine driven generators at the ancient towns of Tel Aviv, Haifa and Tiberias.

The hydroelectric plant will be connected by transmission lines with the lines from the oil-engine stations to establish the beginning of a power system that some day may serve the whole of the Holy Lands. Factories there are now operated by electric power and the use of electric appliances in the homes is becoming more and more common.

TREMENDOUS WASTES DUE TO BAD LIGHT

The bugaboo of bad light in schools and factories is no imagination, according to Guy A. Henry of New York, general director of the Eyesight Conservation Council of America. Speaking at Boston May 28 he stated that one-third of the six million retarded pupils in American schools were in their present condition because of neglected eyesight that could be partially corrected by proper illumination. Factory waste chargeable to poor lighting, he declared, totals thirty million dollars of industrial waste and industrial accidents due to poor lighting cause an annual loss of 300 million dollars.

Abridgment of

Lightning and Other Experiences with 132-Kv.-Steel Tower Transmission Lines, and its Bearing on Tower-Line Design from the Continuity of Service Standpoint

BY M. L. SINDEBAND* and P. SPORN*
Member, A. I. E. E. Associate, A. I. E. E.

Synopsis.—*A large number of transmission lines have been erected without adequate consideration having been given to the ability of the line to stay in circuit electrically during the occurrence of lightning or other disturbance conditions. These come, however, within the range of the transmission engineer's field of action.*

The author's experience with a 55-mi., 132-kv. transmission line since 1917 to date is cited, the particular line being one which has been very successful from a standpoint of continuity of service. Further experience with other lines built with variations on the original design and placed in service in 1924 and 1925 is given. A detailed analysis is given of eighty-eight cases of lightning trouble on one of these lines during 1925, the various steps taken to reduce the frequency of this trouble, the effect of increased clearances and separations, of additional insulators, of flux control units, and of arcing horns and shields on the amount of trouble and on the damage to insulator and conductor are discussed both from the standpoint of actual experience and from the laboratory analyses and investigations made.

A general discussion of the ground wire and its effect on lightning voltages is given and the arguments for and against it are discussed. The importance of paying attention to the mechanical side of the ground wire and the effect of such attention on continuity of service is pointed out.

A summation is given of the analysis and experience of the authors in operation of 132,000-volt lines as applied to transmission line design from the standpoint of continuity of service.

LIGHTNING disturbances, if they are electrostatic disturbances, are, of course, beyond the control of the engineer but the effects of these disturbances on the transmission system are partly within his control and are within his province of action, and any transmission line that is not designed with a view to properly standing up under lightning conditions, has, of course, not been adequately designed. It is an undoubted fact that a good many lines have been designed in the past, and even in the last five years, where the factor of the ability of the line to stay in circuit under lightning disturbances has not been adequately taken into consideration and it has taken actual operating experience to disclose that fact.

132-Kv. Lines Considered

The author's first extensive experience with a 132-kv. line was with the 55-mi. transmission line built on double-circuit steel towers and running from the Windsor Power Plant of the Ohio Power Company and of the West Penn Power Company, located approximately 12 mi. north of Wheeling, W. Va., to Canton, Ohio, the line running in an approximately straight northwestern direction. A sketch of this tower as well as pertinent design data is shown in Fig. 1. This line is equipped with two-ground wires, 3/8 in. diameter Siemens-Martin, and was placed in operation late in 1917. The line is insulated with 10 disk units at suspension points and 12 units at dead-end points. When this line was put into operation there were operating four 30,000-kv-a. steam turbine units at the Windsor Plant and these constituted practically 80 per cent of the capacity connected to the 132-kv. transmission system of which these two lines formed a part. The line has had altogether 41 interruptions due to lightning since it was put into service, and divided by years as follows:

1917	2	1921	4
1918	4	1922	6
1919	3	1923	4
1920	5	1924	6
1925	7		

In 10 per cent of the cases both lines were affected. All but four of these interruptions were such that they did not affect in any way the insulators or the conductor nor did it require any work to repair these. On the four other occasions mentioned the insulator string was flashed and damaged to a point necessitating a change and the conductor dropped to the ground. The ground wire was removed from over all the railroad crossings on the Windsor-Canton line during 1924, the work being completed by the end of August. In 1925, 12 mi. of ground wire were removed at each end of the line, this being done as a precautionary measure. The wire was actually not in very bad condition but atmospheric conditions at both ends of the line were rather bad and there was danger of deterioration developing to a point that would be dangerous. Up till now this wire has not been replaced. It will be noticed from the operating record that the number of interruptions apparently did not in any way increase due to the removal of this ground wire although perhaps a sufficient time has not elapsed for this point to be known definitely. Thus much is known, however; all the trouble encountered in 1925 was on sections where ground wire was installed. It will be noted that in general the history of operation of this line has been a highly successful one, and that the line has given such uniform continuity of service as to make possible the supplying of a load to the City of Canton amounting to well over

*Both of American Gas & Electric Co., 30 Church St., New York, N. Y.

Presented at the Regional Meeting of District No. 1, of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

60,000 kv-a. dependent entirely upon the transmission line for its power.

During 1923 and 1924 the construction of three additional lines in Ohio was undertaken as follows:

1. A 73-mi., double-circuit line from the Philo Plant of the Ohio Power Company, located at Philo, Ohio, on the Muskingum River, south of Zanesville, and running to Canton, Ohio.

2. A 15-mi., single-circuit line, but strung on the same type of towers as the Philo-Canton line, running from Philo to Crooksville, Ohio.

3. A 45-mi., single-circuit line from Fostoria, Ohio, running approximately southwest to Lima, Ohio. This line, too, was to be built on a double-circuit transmission tower with only a single-circuit strung.

During 1924 and 1925 there was again constructed a 129-mi. line of the same type of structure, with only a single-circuit strung but utilizing 397,500-cir. mil., A. C. S. R. instead of 336,400 A. C. S. R. used on the three lines previously mentioned. This line runs from Lima, Ohio, to the Twin Branch, Indiana, plant of the Indiana & Michigan Electric Company which is located on the St. Joseph River, approximately 8 mi. east of the city of South Bend.

The tower utilized on all these lines is shown in Fig. 2. Comparing Figs. 1 and 2, it will be noticed that a number of changes were made between 1915 when the Windsor-Canton tower was designed and 1922 when the Philo-Canton tower was designed. It will be seen that the height of the bottom crossarm was raised from 50 ft. to 64 ft., the vertical crossarm spacing was raised from 12 ft. to 13 ft. and the height of the upper crossarm was raised from 74 ft. to 90 ft. Further, while the Windsor-Canton tower was designed and erected with two ground wires, the Philo-Canton and other towers were all designed for but one possible ground wire and none was actually installed. A large number of factors brought about this change in the design:

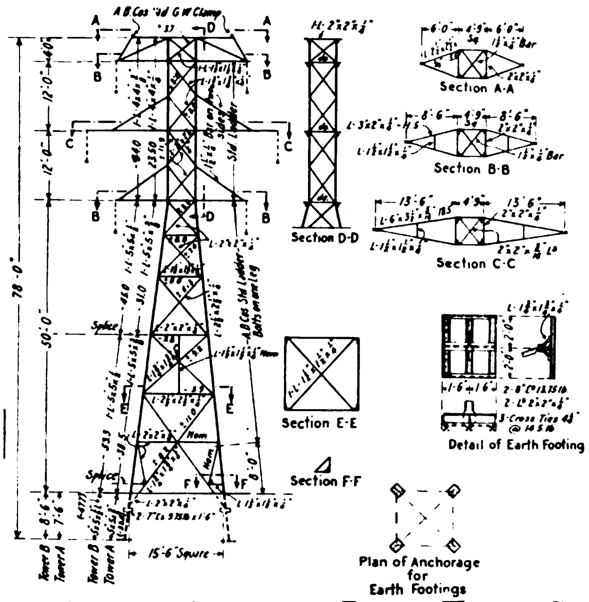


FIG. 1—STRAIGHT SUSPENSION TOWER—WINDSOR-CANTON LINE (1916)

1. In the first place, transmission line construction costs increased greatly between 1917 and 1922. The increase was not only brought about by the increased cost of materials and the higher cost of labor, but also by the increasing cost of right of way. A definite conviction had come about that lines were costing too much and that an attempt should be made to lower the cost, and the most logical and natural suggestion was the lengthening of the average span, making possible, of course, fewer points of anchorage along the right of way, fewer points of suspension and less steel in towers, etc.

2. It seemed logical to conclude that a line with fewer points of support, that is a line with fewer insulators in it, would be better electrically.

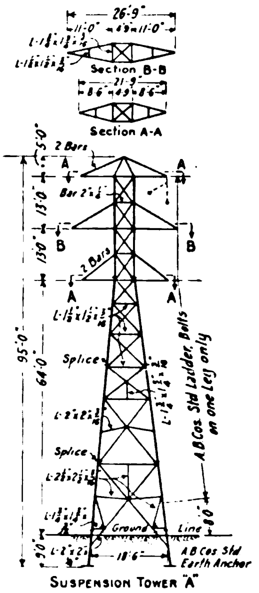

FIG. 2—STRAIGHT SUSPENSION AND SMALL ANGLE (FIVE DEG.) TOWER

Philo-Canton, Philo-Crooksville, Fostoria-Lima, Twin Branch-Lima: Lines (1923-1925)

3. By lengthening the spans, it was possible to take full advantage of the additional mechanical strength obtainable in a steel-reinforced aluminum cable which, from a conductivity standpoint, it was possible to purchase on a cheaper basis at the time these lines were built than straight copper.

4. The experience that had been obtained both in the operation of the Windsor-Canton line and in the operation of a large number of 66,000-volt lines, some of which had been equipped with ground wires and others of which were not, as well as the correlation of similar operating experience of other engineers over that same section of the country, seemed definitely to indicate that the ground wire was doing more harm

than good on the lines about which anything was known, on operating voltages up to and including 132,000 volts. Definite examples extending over years were cited by the operating people to show that removal of the ground wire over sections of line where such ground wire had been giving trouble due to the ground conductor getting entangled in the main conductors under storm conditions or to breakage in other ways, had materially improved system operation and caused in no case any increased trouble. In fact, there did not seem to be any cases of trouble that could definitely be ascribed to the omission of such ground wires. In short, operating experience, although perhaps not properly evaluated, seemed to show that the ground wire was doing more harm than good and that an improvement in operation could be obtained by its omission. It was known, of course, that where the ground wire had given trouble it was brought about by mechanical weakness and that it was possible to install a ground wire free from such trouble, but when the expense of this was taken into consideration and balanced against the then existing experience, it did not seem worth while to make this additional expenditure.

The Philo-Canton and Philo-Crooksville lines were put into service in September, 1924, the Fostoria-Lima line was put into service August 1924, and the Twin Branch-Lima line was put into service September 1925, all of them being put into operation initially at the rated voltage, that is 132,000 volts, with the exception of the Fostoria-Lima line, which was operated at 66,000 volts until September 1925 when it was cut over to 132,000 volts. Very little trouble was experienced with the Philo-Canton line during 1924 although definite records are not available. It is believed, however, there were actually no flashovers. The history of this line during 1925 is shown in the tabulation under Table I which gives in as complete detail as was possible to obtain, 88 cases of trouble on the line. The experience falls naturally into four groups:

1. The group covered by cases 1 to 15 inclusive
2. The group covered by cases 16 to 35 inclusive
3. The group covered by cases 36 to 68 inclusive
4. The group covered by cases 69 to 88 inclusive

Analysis of the Four Groups

An examination of the first 15 cases of trouble shows that all but one case of trouble were exclusively in the top conductor. In 11 of the 15 cases one or more insulators were shattered and in 13 of the 15 cases considerable damage was done to the conductor. The question of the arcing and the points between which the arc took place has never been definitely cleared up although the table attempts to show how this actually happened. A check-up on this information, however, disclosed that the field inspectors in many cases were able to get no definite evidence and in a good many cases guessed as to what happened, very often not guessing correctly. However, the information was the best obtainable and has been allowed to stand for whatever light it may throw on the situation. It is perhaps pertinent to point out that the question of field information in all these cases is generally the most difficult question to take care of and is one of the reasons, perhaps, why so much loose thinking has been done on the subject.

The second group, covering cases 16 to 35, embodies experience on the same line with the so-called flux control units. The theory underlying it has been set forth by Mr. A. O. Austin in a group of papers which are given in the bibliography. The underlying idea is that an insulator placed at the end of the horn and mounted below the insulator string will give a screen effect and will prevent the formation of so-called streamers on the conductor and subsequent ionization and eventual breakdown of the air surrounding the insulator. Regardless of the apparent weakness of the theory, it was nevertheless decided to give this system a trial in view of the fact that information (and this information again had to be obtained in a hurry with no chance for proper investigation or check-up) given by other operating companies having systems of the same voltage was very emphatic in the statement that the application of this system had resulted in an almost complete elimination of the flashovers on their systems. It therefore seemed advisable, while the lightning season was on and in view of the fact that this equipment could be installed in very quick time, to give it a trial and find out exactly what it was worth. Consequently the two top conductors of the Philo-Canton

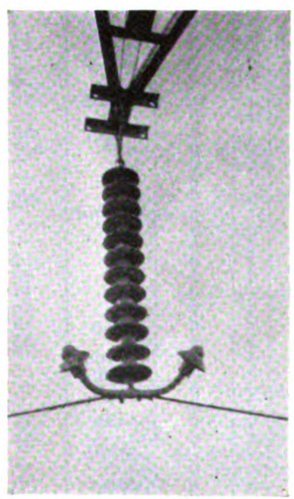

Fig. 3—Installation of "Flux-Control" on Philo-Canton Line

The change to 12 units was a later change, the original installation consisting of 9 units

line were equipped with these controls, one of the 10 units being removed to allow its installation without lessening the ground clearance. A typical view of such an installation is shown in Fig. 3. It shows,

however, 12 units in the string, this being a change which will be discussed later. The original installation, however, went in with nine disk units.

An examination of cases 16 to 35 shows that the installation of these controls in no way minimized the trouble nor was there any change in shifting of the trouble from the top conductor to the other two conductors; in other words, all cases of trouble in this group were exclusively in the top conductor. The one marked change was that the shattering of the insulators seemed to be confined more closely to the two top units, the control assembly acting apparently as a not overwell designed horn and as such being subject to considerable burning of its own. This is shown in

Figs. 4 and 5, which are quite typical as to what happened to some of the horns after flashover.

The next group, which covers cases 36 to 68, covers a period during which a new series of changes was made on the line in an attempt to see whether, without resorting to a ground wire, flashover could not be prevented or reduced to a point where its effect would be harmless or practically so. In view of the fact that the

so-called flux control unit very definitely did not seem to do what the sponsors claimed it would do, it was decided to test out three other changes and these consisted of the following:

1. The top-arm was extended two and one-half feet in each direction, making it the same length as the middle arm and the hanger of the middle arm was lowered approximately 2 ft., 10 in. on the cage. This is shown in Fig. 6. This made it possible to increase the insulation on the top arm, where the trouble again seemed to be centered, from the original 10 units to 12 units, and this change was made on the entire line. This, of course, was based on the theory that the lightning voltages were not very much in excess of the flash-

over voltage of the top string and it was thought possible that the installation of two additional units would raise the flashover of the string to such a point that the

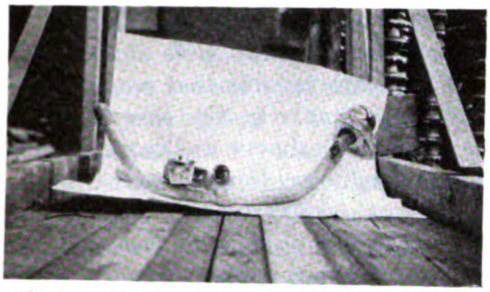

FIG. 4—TYPICAL BURNING OF "FLUX-CONTROL" HORNS AND INSULATORS PHILO-CANTON LINE (1925)

induced voltage would not exceed the flashover voltage of the string in at least, say, 90 per cent of the cases.

2. The moving out of the point of attachment of the top string of insulators resulted in a greater clearance between it and the second arm hanger. The object of this, of course, was to increase the flashover distance to the surrounding structure.

3. In addition to these changes which were carried through not only on the Philo-Canton line, but also on the Philo-Crooksville, Fostoria-Lima, and Lima-Twin Branch lines, there was installed on the Philo-Canton line the following equipment:

An 18 in. times 22 in. cast-iron arcing ring was em-

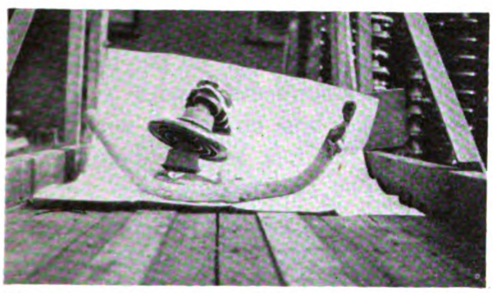

FIG. 5—TYPICAL BURNING OF "FLUX-CONTROL" HORNS AND INSULATORS PHILO-CANTON LINE (1925)

ployed on the lower end of the upper string and a 24-in. arcing horn mounted parallel to the conductor. This assembly was used on only one side of each tower and the flux control assembly was maintained on the opposite side, alternating the position of the two on successive towers so that for each circuit there were installed an equal number of arcing rings and "flux controls." There was no change made in the flux control assembly from what was originally employed with the exception of the fact that three-insulator units were added (making 12 in all); also where any damage had been done to the assembly the damage was repaired.

Fig. 7 shows a straight-arcing ring and horn-suspension assembly, and Fig. 8 is a drawing of this same assembly.

In the case of dead-end assembly a 33-in. diameter-pipe ring with a double horn was employed; Fig. 9 is a photographic view of such an assembly after the flashover described under case No. 78.

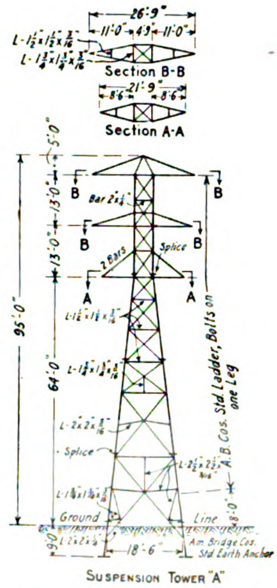

FIG. 6—CHANGES MADE IN UPPER AND MIDDLE ARMS PHILO-CANTON LINE (1925) TO OBTAIN LARGER CLEARANCE

While the troubles listed under cases 36 to 68 were taking place, the changes enumerated above were being made all at the same time, the changes being made on only one circuit at a time during the daytime and the circuit being put back into service at night. It will

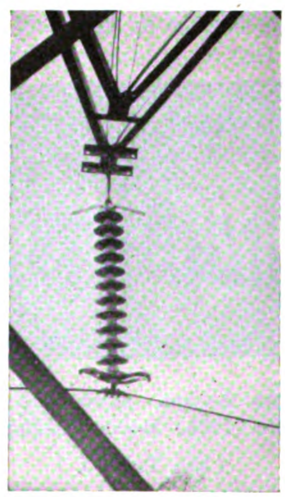

FIG. 7—ARCING RING AND HORN ASSEMBLY, PHILO-CANTON LINE (1925)

be noticed that in 24 of the 33 cases, the trouble was again on the top conductor and that in all but five of the cases the flux control was employed. In general the type of damage was the same as that in group two, consisting of considerable damage to the string, to the conductor, and to the flux control unit. Where no

arcing protection of any kind was employed, that is on the middle and bottom conductors, the damage in some cases was more severe and in other cases less than in the two upper conductors. It is to be noted that among this group, while there were some units in service with the arcing ring protection, there were no cases where any damage was sustained to units with such protection.

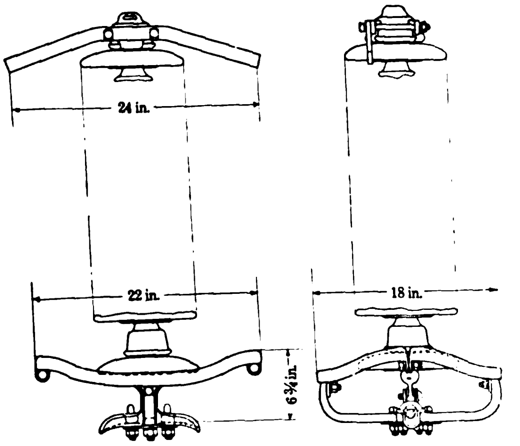

FIG. 8—ARCING RING AND HORN ASSEMBLY FOR SUSPENSION TOWER PHILO-CANTON LINE (1925)

The last group, namely cases 69 to 88 inclusive, extended over a period of time of well over two months and during the course of this period no changes of any kind except those described previously, were made. It will be seen that of the 20 cases, 13 occurred on the top conductor, five on the middle conductor, and two on the bottom conductor. Of the 13 top-conductor failures, seven were cases in which flux control had been employed and six in which rings and horns had been employed, but with this difference: in five of the seven cases employing flux control one or more insulator units were shattered, but only in three of the six cases employing rings and horns were any insulators damaged. Again, while in four of the seven flux-control cases there was damage done to the conductor, and in the case of the rings and horn combination three of the six cases resulted in damage of conductor, the extent of the damage in the case of the horn combination seems to have been less than in the case where the flux control has been employed.

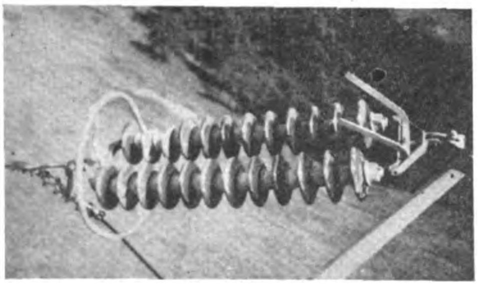

FIG. 9—DEAD END ARCING RING AND HORN ASSEMBLY PHILO-CANTON LINE (1925) AFTER FLASHOVER CASE NO. 78

(See Table I.)

The troubles encountered on the Twin Branch-Lima and the Fostoria-Lima lines were almost negligible in comparison with the trouble that was encountered on the Philo-Canton line. In the case of the Fostoria-Lima line only one flashover was experienced and that was on a top conductor during a period when the line was operated at 66,000 volts. The conductor was slightly damaged but no damage was sustained to the insulators. In the case of the Twin Branch-Lima line only three cases of flashovers due to lightning were experienced in 1925, two being on the top conductor and one on the middle conductor. In each of these cases at least two insulators were shattered but no damage was done to the conductor. On the Philo-Crooksville line in a period of considerably over a year, there were two cases of flashover but neither case caused trouble of serious consequence.

RELAY PROTECTION

At the beginning of 1925 the following scheme of protection was employed on the Philo-Canton line. At the Philo end current-balance relays were employed, operating only in case both lines were in circuit, and separate overload relays were employed on each of the two lines. The balance relays were operating on a so-called cross-connection and the lines were interlocked with a locking-out relay to render the second line non-automatic for a period of five sec. in case of the functioning of the switch on the first line. At the Canton end, cross-connection with a duo-directional reverse power relay was employed with fast and slow overload relays, the fast relays operating only with both lines in. The two feeders here were also interlocked with a five sec. locking-out relay. As the lines continued to be damaged some changes were made in the direction of speeding up the interlocking time and also in the direction of speeding up the relays at the Canton end. In October, there were installed at the Canton end of the line a set of current-balance relays similar to those at the Philo end but the duo-directional reverse power relay was maintained to select between the Windsor-Canton and Philo-Canton lines in case of one-line operation throughout. In general, the relays functioned entirely satisfactorily and it is not believed that the severe burning which took place was caused in any way by the failure of the relays to clear the circuits quickly enough, the relay settings being as fast as could possibly be obtained without endangering normal operation.

A MORE DETAILED ANALYSIS OF TROUBLES

While these troubles were occurring it was impossible to get any accurate data as to what was happening. Lines were flashing-over; insulators were being shattered; the conductor was being burned; and the field

forces were too busy trying to place the line in an operating condition with a minimum delay to be able to give very much attention to the details of what was happening. Things were happening so thick and fast that there was no opportunity to stop and consider the matter calmly. With the approach of the end of the lightning season a little more time could be taken to determine what had actually happened and to make an intelligent analysis.

First, toward that end, was the gathering together of data with regard to the trouble shown in the tabulation under Table I. This tabulation was very carefully gone over and a survey was made in the field to supplement, if possible ,the information given therein. In the course of this investigation it was found how very little knowledge as to what actually happened was obtainable and the smallness of the amount was really surprising. It was found, as a careful review of the troubles tabulated in Table I will show, that there existed a good deal of conflicting data and that a good many of the reports which were supposed to have been based on observation at the time the repairs were made, were entirely unreliable. However, this much stood out with bold clearness. The Philo-Canton line had been subjected to an unusual amount of punishment from lightning. That it was due to the fact that the area which it traversed was a particularly stormy area there was very little doubt. There also did not seem to be any doubt that the measures that had been taken up till then were none of them completely effective and some of them were almost negligibly so. Further, a calm review of what had been done and the lines that had been followed brought home clearly the fact that designing a line merely to withstand lightning voltages was certainly not a proper procedure since it resulted in placing insulation on the lines of such a value that it could not possibly be matched economically by that of the transformers, oil switches, and other apparatus connected to the system.

Simultaneous with the gathering of the field data a very thorough review was made of the work in connection with this subject done by Steinmetz, Creighton, Austin, Peek and others, and particularly their work in connection with the ground wire.

Viewing the troubles encountered on the Philo-Canton line, after an analysis had been made of all the available field data, and in the light of the work of the other investigators mentioned, the explanation that seemed to stand up best came down to the following:

1. The Philo-Canton line traverses an unusually stormy country and the year 1925 seems to have been an unusually severe year from the standpoint of lightning.

2. The height of the particular tower was considerably higher than any that had been previously constructed on the system and this resulted in potentials being induced in the upper two conductors during lightning higher than those that were encountered on the Windsor-Canton line by at least 300,000 to 400,000 volts.

3. The omission of the ground wire subjected the insulator strings to this full voltage and this value was sufficient often enough during 1925 to give the large number of cases of trouble that are tabulated.

4. The fact that the Twin Branch-Lima and the Fostoria-Lima lines were not subject to these flashovers can be explained by the following:

   a. The first of these two lines did not operate for a sufficiently long period during the lightning season.

   b. The Fostoria-Lima line was in for a whole year but most of the time it was operating at 66,000 volts and its performance when insulated for 132,000 volts with a follow-up voltage of 66,000 volts would, of course, be expected to be considerably different from what it would be with a follow-up voltage of 132,000 volts.

   c. From general observations taken, it appeared indisputable that the lightning in the territory traversed by these two lines was not anywhere near the same severity as that encountered along the Philo-Canton line.

Viewed thus a satisfactory solution seemed attainable by adopting the following methods:

1. Preventive. Installation of ground wire to reduce the lightning voltages.

2. Remedial. Where, either because of the severity of the lightning or because of the great importance of the load, no *chances* could be taken, the installation of arcing rings and horn devices to clear the insulator string and the conductor in case of spill-over.

Before definitely embarking on this course, it seemed advisable to check this proposed solution and consequently a series of tests was carried out with the lightning generator of Peek to determine the effectiveness of the ground wire on the tower shown in Fig. 2. These tests showed definitely that a reduction amounting on the average to about 50 per cent in the value of the induced voltage could be obtained by the installation of one ground wire at the peak of the towers. This is shown in Fig. 10, which shows the induced potential in A, suspension, B, moderate angle, and C, dead-end towers—the height of the crossarms is the

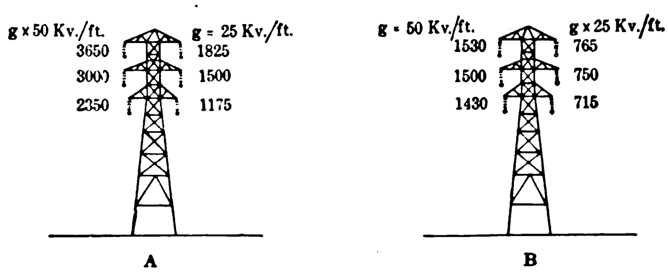

FIG. 10—GROUND WIRE TESTS ON PHILO-CANTON 132 K. W. TOWER

A. No ground wire B. With ground wire

same in each case and is shown in Fig. 2—with and without ground wires, under conditions of a potential gradient of 50-kv. per foot of height, and of 25-kv. per foot of height.

Another phase of the investigation was a series of tests in connection with the arcing rings and horns which it was thought advisable to employ on the towers traversing territory particularly susceptible to lightning. Before working out the designs, a series of tests was

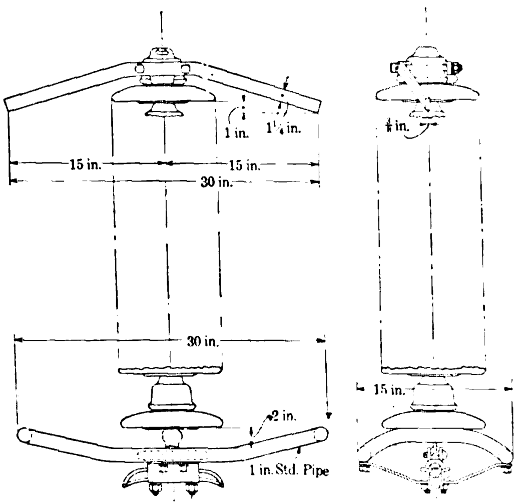

Fig. 11—Arcing Ring and Horn Assembly (1926 Installation) for Single Suspension String—Philo-Canton Line

carried out in the high-voltage engineering laboratory at Pittsfield, to determine the specific shapes and sizes of horns and rings and their placement on the string to clear a power arc from the insulator string and from the

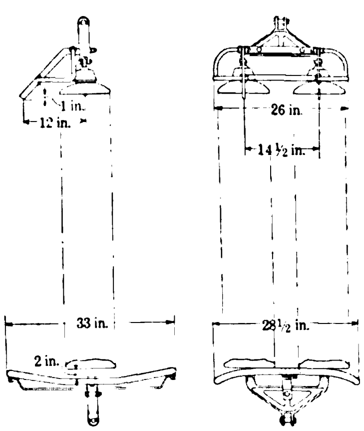

Fig. 12—Arcing Ring and Horn Assembly (1926 Installation) for Dead End String Philo-Canton Line

conductor if flashover should take place and should be followed by a power arc. The rings and horns that were worked out as well as their relations to the string and to the conductors are shown in Figs. 11 and 12 which show the designs for a straight suspension string and for a straight dead-end string. A similar design was worked out for the double suspension string.

As a result of all these studies and investigations, ground-wire installation was decided upon on all 132-kv. steel tower lines that had been erected since the beginning of the Philo-Canton line, or that were in process of erection by the end of 1925, all of which were erected without ground wire. In addition, arcing rings and horns were laid out for the Philo-Canton line and for a number of other lines where either, as in the case of Philo-Canton, it was known that lightning conditions were very bad, or where, because of the existence of but a single circuit between stations, it was imperative to keep the outage time in that circuit as near zero as possible.

Design of Ground Wire and Connections

It is conceded among engineers that the disrepute into which the ground wire had fallen was due primarily to the fact that it had been put up more or less on the basis that it was merely an appendix to the line, and since it was not carrying any energy, and therefore not earning its way, that it ought therefore to be put in with as little expense as possible; this resulted in almost every case in the installation being as poor a one as possible. The conductors employed were very seldom anything but galvanized steel wire, and that was generally of a very much smaller diameter than the main conductor and of a lesser number of strands. The attachment was generally of some clamp type; the sagging of the ground wire was given very little consideration; and all in all the thing was put in in a most non-engineering manner. As a consequence troubles of all sorts were encountered with the ground wire. Three or four years after the installation the wire as a rule would begin to rust and a short time after that breakages would crop out in various sections of the line, resulting in grounds and short circuits being placed on the system. In many cases, too, the main line would swing into the ground wire or the ground wire into the line due to their unequal sags or due to their unequal swings.

It has always been known that if a ground wire similar to the main conductor were employed and the same attention given to its installation as given to the main conductor, these troubles could be avoided, but with the exception of a very few cases the authors do not know of any installations that were put in on that basis. In view of the fact that the decision to install the ground wire was reached after considerable trouble without it, and after a conviction that the ground wire would remedy a considerable portion of this trouble, it was deemed advisable not to repeat the mistakes of handicapping the ground wire through poor installation. On the other hand, it was felt that if there were any ways that the installation could be made cheaper than that which would obtain by the use of a straight line conductor, advantage should be taken of these means. Accordingly, there was worked out in conjunction with the conductor manufacturer, a special 159,000 cir. mil. A. C. S. R. conductor con-

sisting of twelve 0.1151 in. diameter aluminum strands and seven 0.1151 in. steel strands, and this conductor was found to have mechanical characteristics so closely similar to that of either 336,400 or 397,500-cir. mil that under most conditions it could be used interchangeably with them.

More attention than is usual was given to the hardware and to the method of attachment of the ground wire.

APPLICATION OF EXPERIENCE TO TOWER LINE DESIGN

The authors believe that theoretical analysis and their experience in operation applied to tower-line design with a view particularly of designing the lines for continuous service can be summed up as follows:

1. It is essential that a balance be maintained between the height of tower, the length of span, and the lightning voltage that may be expected in the conductor span. As a general rule the cost of the line can be decreased by increasing the length of span, but carried beyond a certain point the continuity of service to be expected from the line is bound to be decreased materially in the raising of the height of the conductors. The standard suspension insulator has been developed to such a point at the present time that the increased number of points of attachment on the line will have materially less effect on lowering the continuity of service than will the raising of the height of the conductor.

2. A proper balance should be maintained between the number of insulators employed per string, the insulating values employed on other apparatus on the system, and the clearance to ground. Insulating a line sufficiently high to prevent flashover in a great majority of cases, will result as a general rule (except perhaps in certain types of lines operating at 220 kv. or higher voltages) in overinsulating the lines at the expense of the rest of the equipment and will result in failures at station and substation points.

3. Unless the line is very low, it is believed that steel-tower structures carrying power conductors of 44,000 volts and over should in general be designed and installed with a ground wire. It is fully realized that there may be locations and conditions under which this is not practicable, for example, in territory where the soil conditions are such that the ground resistance is very high, and where consequently the effectiveness of the ground conductor is minimized to an almost negligible value; but these are special cases. There may also be cases in territory that is particularly lightning-free where no ground wire would be justified. In no case, the authors believe, should the use of a ground wire be dismissed without giving full consideration to the known lightning conditions of the territory over which the line has to traverse, to the height of the tower, to the insulation proposed for the tower, and to their relations to the lightning voltages that might be expected on the power conductors.

4. If a ground wire is installed it should be accepted as an essential part of the line and its installation treated the same as that of the main conductors, full attention being given to the material of the conductor itself and to its method of attachment and stringing. There is no reason why the main power conductor should be designed for a possible 50 years of life and the ground conductor designed for a life equal to 10 per cent of that.

5. It is possible that a line will have to be built of so great a height, because of the contour of the country or for some other reason, that even with the use of a ground wire, sufficient protection will not be obtained to keep the number of flashovers down to a low enough point. In these cases, the authors believe it would be well to install remedial devices in the form of arcing rings and horns or their equivalents to prevent conductor burning and insulator shattering in case of a flashover.

6. The line must be designed so that its switching arrangement is correct; that is, the line must be so designed that it can be relayed properly and disconnected from the rest of the system quickly in case of trouble.

Acknowledgment is hereby made to Mr. F. W. Peek, Jr., and Mr. W. L. Lloyd, Jr., of the General Electric Company, and to Mr. A. O. Austin of the Ohio Brass Company for their assistance in carrying out some of the investigations, and to Mr. Frank Howard, of the Ohio Power Company, for his assistance in carrying through some of the developments and in obtaining the field data.

The complete paper gave a complete record of the relay settings on the Philo-Canton line during 1925, a discussion of the action in regard to the design of new towers taken during the period of trouble, a discussion of the research work on the subject of the ground wire done by various investigators, the results of an investigation of the relationship between the length of the insulator string and clearance of the string to ground to obtain a balance between the two, and an outline of plans for obtaining complete information on the future behavior of these lines.

NEW ELECTRIC CODE FOR MEXICO

Demand for electrical supplies in Mexico have been stimulated by the issuance of a new electric code, which raises the standard of permitted equipment. Existing installations shall be made to conform to the new code by July 11, 1926, but the Department of Industry, Commerce, and Labor is authorized to extend the period if necessary.

The code is an adaptation to Mexican conditions of codes of the United States. The National Electrical Code and the National Safety Code are drawn on extensively. A number of changes from American practises are introduced, such as longer spans between poles and more lenient wiring regulations, as there is considerable use of stone and concrete in the construction of Mexican homes.

Zero Method of Measuring Power with the Quadrant Electrometer

BY W. B. KOUWENHOVEN*
Member, A. I. E. E.

and

PAUL L. BETZ†
Student Member, A. I. E. E.

Synopsis.—*This paper describes a zero method of measuring power by means of the quadrant electrometer developed by the authors, and which we believe to be new. Zero deflection of the electrometer is obtained by opposing the torque produced by the a-c. load by means of a counter torque set up by continuous potentials introduced into the electrometer circuit. The continuous potentials required are small in value and easily handled.*

We have derived the equations that apply to the method and checked their correctness by experimental observations on resistance, capacity, and inductive circuits.

THE importance of the quadrant electrometer as an instrument for measuring the power factor and loss in dielectrics and cables is well recognized. The quadrant electrometer wattmeter has also prove valuable in measuring iron losses in small specimens.

The usual connections for using the quadrant electrometer as a wattmeter are shown in Fig. 1. In Fig. 1, N is the needle; Nos. 1 and 2 are the respective quadrant pairs which are enclosed in the case of the electrometer. The deflection of the electrometer is proportional to the vector product of the load voltage V and the voltage drop across the quadrants, 1 and 2, caused by the load current I flowing through the non-inductive resistance R_1. If it is impossible to apply full voltage to the

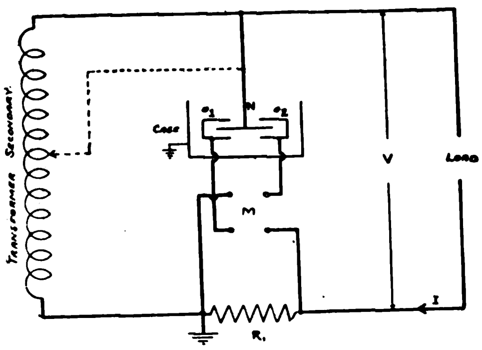

FIG. 1—QUADRANT ELECTROMETER WATTMETER

needle of the electrometer, a fractional part of the supply voltage may be applied to the needle as indicated by the dotted line in Fig. 1. Right and left deflections are taken at each load by means of the reversing switch or commutator, M, and the power consumed by the load is given by equation (1)[1].

$$I\,V\cos\varphi = \frac{1 + R\left(\frac{V}{n}\right)^2}{2\,b_1\,R_1}\,n\,(\beta - \alpha) - \frac{2-n}{2}\,I^2\,R_1 \qquad (1)$$

Where

I = Load current in amperes
V = Load voltage in volts
$\cos\varphi$ = Power factor of the load
R_1 = Value of the non-inductive resistance in ohms
n = The factor by which the voltage applied to the needle must be multiplied to give the load voltage V
α = Deflection of the electrometer with the commutator vertical
β = Deflection of the electrometer with the commutator horizontal
R = An electrometer constant called the needle constant
b_1 = An electrometer constant

The quadrant electrometer wattmeter may be used as a deflection instrument as described above, or it may be used as a zero instrument by a method developed by Simons and Brown[2]. Simons and Brown showed that the deflection may be reduced to zero by the insertion of a resistance in the needle circuit of the instrument. The insertion of the proper value of resistance enables one to bring the voltage applied to the needle in quadrature with the voltage drop across the resistance R_1 and thereby reduce the deflection to zero. The power factor of the load may then be calculated from equation (2)[2].

$$r_2\,c_2\,\omega = \cos\varphi + \frac{2-n}{2}\,\frac{I\,R_1}{V} \qquad (2)$$

Where

r_2 = The resistance inserted in the needle circuit
c_2 = The capacity of the needle circuit
f = Frequency
$\omega = 2\pi f$

and the other symbols have the same meanings as those used in equation (1).

The zero method of Simons and Brown possesses certain limitations, as pointed out by them,[3] on capacity loads of low power factor where n is large. This method is difficult to use on loads of high power factor because of the large value of resistance required for insertion in the needle circuit, and is not applicable to inductive

Presented at the Regional Meeting of District No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

circuits unless the needle voltage is reduced to a small fraction of the load voltage.

I. Theoretical

Zero or balance methods are in general more accurate than deflection methods, and their advantages are too well known to require discussion here. This paper describes a new zero method of measuring power and power factor with the quadrant electrometer. The method is applicable to inductive, resistance, and capacity loads and is independent of the value of the fractional part $(1/n)$ of the load voltage applied to the needle.

The zero method described here depends upon the use of continuous potentials to reduce the deflection of the electrometer to zero. A continuous potential is applied to the needle in addition to the a-c. load voltage and a second continuous potential is introduced into the quadrant circuit in addition to the drop across the resistance R_1, caused by the alternating-load current. The polarity of these two continuous potentials is arranged so that their effect opposes the deflection caused by the alternating potentials applied to the needle and quadrants respectively. The deflection is reduced to zero by adjusting the value of the continuous potentials to the proper value. The advantage of the method lies in its simplicity.

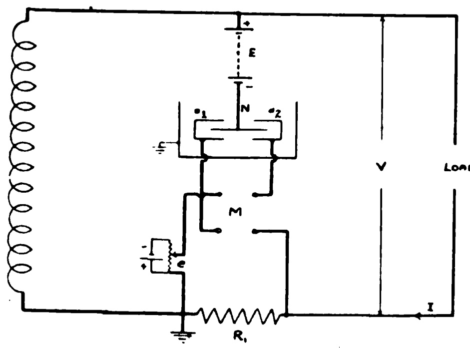

Fig. 2—Connections for Zero Method *A*

A number of arrangements of the connections for introducing the continuous potentials into the circuits of the electrometer have been investigated. Three of these arrangements, called, *A*, *B*, and *C*, respectively, are described in the paper.

Zero Method A. The diagram of connections for zero method *A* is given in Fig. 2, where E equals the continuous potential introduced into the needle circuit of the electrometer and e is the continuous potential introduced into the quadrant circuit; V and I represent the a-c. voltage and current, respectively, and R_1 is the non-inductive resistance.

Three methods of reducing the deflection caused by the a-c. load present themselves; (1) vary both E and e; (2) vary E, e constant; (3) vary e, E constant. Theoretically it makes no difference by which of these methods zero deflection is obtained, but from practical considerations it is simplest to vary e, which is on the grounded side of the instrument, keeping E in the high potential side constant. The variation in e is obtained by using a potentiometer rheostat as shown in Fig. 2.

In making a measurement, two readings are taken in order to eliminate certain electrometer constants. The operation is as follows: Assume that the commutator M is in a vertical position, and that the a-c. circuit is closed. As the instrument begins to deflect, the value of the continuous potential e is adjusted by means of the potentiometer until the deflection equals zero. The value of the potential E and of e_1 are noted. Then the commutator is placed in a horizontal position and the torque due to the a-c. power is again balanced by adjusting the continuous voltage applied to the quadrants. Let e_2 equal the value of the continuous quadrant voltage under these conditions. The experimental results show that the two values of the quadrant continuous potentials, e_1 and e_2, are very nearly equal and, in the equations, the average value e is used without introducing any appreciable error.

Before shifting the commutator from a vertical to a horizontal position, the a-c. circuit and the battery circuit of quadrant voltage, e are opened. This prevents the electrometer needle from deflecting excessively and reduces the time between readings.

Equation (3) gives the general equation of the electrometer which was derived by Kouwenhoven in a previous paper.

$$(1 + R\,V_0^2)\,\theta = -\frac{b_1}{2}V_1^2 + \frac{b_1}{2}V_2^2 + b_1 V_0 V_1 - b_1 V_0 V_2 + c_0 V_0 + c_1 (V_1 - V_2) \quad (3)$$

Here

V_0 = The instantaneous value of the voltage applied to the needle.

V_1 = The instantaneous value of the voltage applied to the quadrant pair No. 1

V_2 = The instantaneous value of the voltage applied to quadrant pair No. 2.

θ = Resulting deflection $(\alpha - \beta)$

α = Deflection with the commutator vertical

β = Deflection with the commutator horizontal

R = Needle constant of the electrometer

b_1, c_0 and c_1 = Electrometer constants

Let v equal the instantaneous value of the load voltage V, and i equal the instantaneous value of the load current I; then with the commutator vertical, we have

$$V_0 = v + i R_1 - E$$
$$V_1 = -e_1$$
$$V_2 = i R_1$$

With the commutator horizontal, the values of V_0, V_1 and V_2 are

$$V_0 = v + i R_1 - E$$
$$V_1 = i R_1$$
$$V_2 = -e_2$$

Substituting these values of V_0, V_1 and V_2 in the general electrometer equation (3) and solving, we obtain

equation (**8**), the derivation of which is given in the mathematical part of the paper.

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e - \dfrac{e^2}{2}}{R_1} - k\,.\,\frac{e}{R_1} \qquad (\mathbf{8})$$

where k is an electrometer constant with a value of $\dfrac{c_1}{b_1}$ as shown in the mathematical part of the paper.

The term, $\dfrac{I^2 R_1}{2}$, of equation (**8**) is a correction term and equals half the loss in the resistance, R_1, which is measured by the electrometer.

If the polarities of the batteries E and e are reversed with respect to those shown in Fig. 2, we find that the power consumed by the load is given by equation (**9**).

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e - \dfrac{e^2}{2}}{R_1} + k\,\frac{e}{R_1} \qquad (\mathbf{9})$$

Equations (**8**) and (**9**) involve only the single electrometer constant, k. The other electrometer constants, that must be determined if the instrument is to be used as a deflection wattmeter, are eliminated.

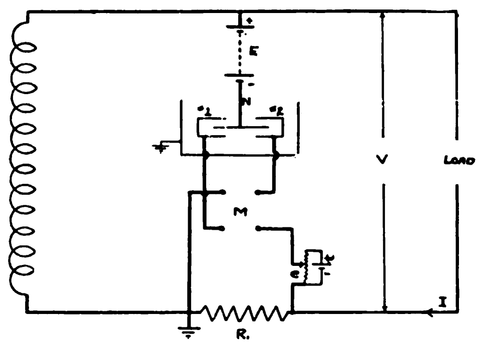

FIG. 3—CONNECTIONS FOR ZERO METHOD *B*

A study of equations (**8**) and (**9**) show that this constant k may be eliminated if we take the mean of two sets of readings. The first set being taken with the connections as shown in Fig. 2, and the second set with the batteries E and e reversed. The constant k, however, can be evaluated very easily as shown in the experimental part of the paper, and the value of the term $k\,\dfrac{e}{R_1}$ determined in each case.

Equations (**8**) and (**9**) were checked experimentally and the results are given in the experimental part of the paper.

Zero Method B. The diagram of connections for zero method B is given in Fig. 3. Two readings are taken for this connection also, in the first the commutator is vertical, and in the second horizontal. When the commutator is vertical

$$V_0 = v + i\,R_1 - E$$
$$V_1 = 0$$

and

$$V_2 = i\,R_1 + e_1$$

With the commutator horizontal, V_0 has the same value as before, but now

$$V_1 = i\,R_1 + e_2$$

and

$$V_2 = 0$$

Proceeding as in connection A, we find that the power consumed by the load is given by equation (**12**) which is derived in the mathematical part of the paper.

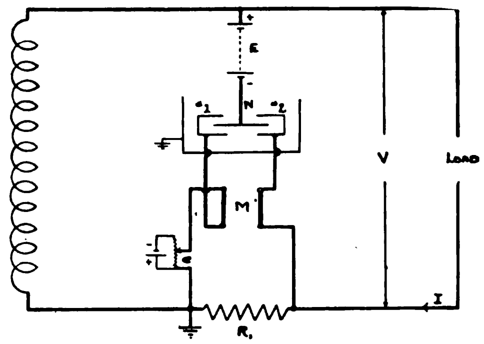

FIG. 4—CONNECTIONS FOR ZERO METHOD *C* COMMUTATOR VERTICAL

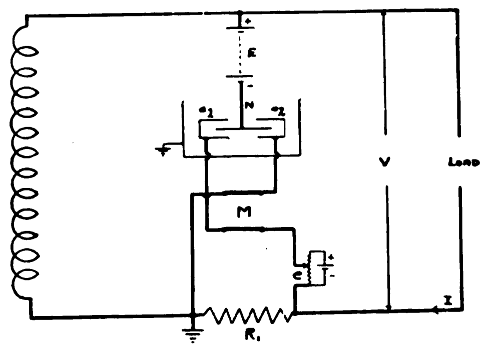

FIG. 5—CONNECTIONS FOR ZERO METHOD *C* COMMUTATOR HORIZONTAL

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e + \dfrac{e^2}{2}}{R_1} - k\,\frac{e}{R_1} \qquad (\mathbf{12})$$

Reversing the batteries E and e, we obtain

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e + \dfrac{e^2}{2}}{R_1} + k\,\frac{e}{R_1} \qquad (\mathbf{13})$$

Experimental proof of the correctness of equations (**12**) and (**13**) is given in the experimental part of the paper.

Zero Method C. The diagrams of connections for zero-method C are given in Fig. 4 and Fig. 5, in which the potentiometers for varying e are not shown.

Zero method C, as may be seen from Fig. 4 and Fig. 5,

is a combination of the two previous zero methods, A and B. A study of equations (**8**) and (**12**) shows that the $\frac{e^2}{2}$ terms are of opposite signs; therefore, this term may be eliminated from the final result by combining the two methods.

In taking a measurement the operation is as follows; with the commutator vertical and the quadrant d-c. voltage in the grounded side of the quadrant circuit,

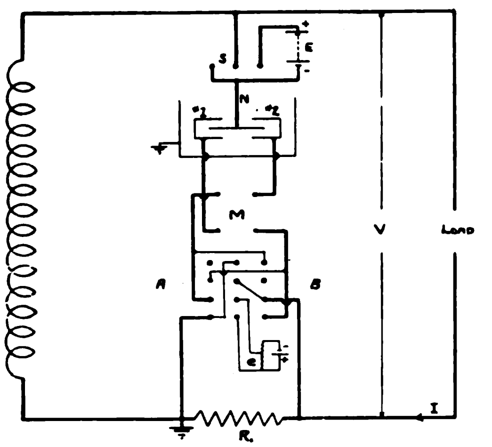

Fig. 6—Switching Arrangement for Zero Methods

as shown in Fig. 4, a balance is obtained between the torque due to the alternating and continuous voltages. Then the commutator is placed horizontally and the quadrant d-c. voltage is thrown to the high side of resistance, R_1, as shown in Fig. 5. and a balance again obtained by adjusting the quadrant continuous voltage.

With the commutator vertical as in Fig. 4, we have

$$V_0 = v + i\,R_1 - E$$
$$V_1 = -\,e$$
$$V_2 = i\,R_1$$

and for Fig. 5

$$V_0 = v + i\,R_1 - E$$
$$V_1 = i\,R_1 + e$$
$$V_2 = 0$$

Substituting these values in the general electrometer equation (**3**) and solving, we obtain (**15**) the derivation of which is given in the mathematical part of the paper

$$I\,V\cos\varphi + \frac{I^2\,R_1}{2} = \frac{E\,e}{R_1} - k\,\frac{e}{R_1} \qquad (\mathbf{15})$$

If the polarities of the two batteries E and e are reversed, we get the relation (**16**):

$$I\,V\cos\varphi + \frac{I^2\,R_1}{2} = \frac{E\,e}{R_1} + k\,\frac{e}{R_1} \qquad (\mathbf{16})$$

Test data are given in the experimental part of the paper to prove the correctness of equations (**15**) and (**16**).

The battery e may be thrown from one side to the other side of the circuit by means of two double-pole, double-throw switches, or a single, four-pole, double-throw switch, and the connections shown in Fig. 4 and Fig. 5 are combined in a single switching arrangement shown in Fig. 6. It is possible to use zero methods A, B, or C by means of the connections shown in Fig. 6.

A single-pole, double-throw switch, S, is shown in Fig. 6 in the needle circuit. This switch when thrown to the left connects the needle directly to the line and permits bringing the mechanical and electrical zeros into coincidence. When the switch S is thrown to the right the battery E is connected in the needle circuit.

When the four-pole, double-throw switch shown in Fig. 6 is closed on the side marked A, the connections are such as to give zero method A. When closed on the opposite side, B, connections are made for zero method B. For zero method C the four-pole, double-throw switch is closed on side A when the commutator M is vertical and on side B when the commutator is placed horizontal.

Method C eliminates the term $\frac{e^2}{2}$ from the equation and is therefore simpler to use from the standpoint of calculation. We can determine k by taking several electrometer readings in a circuit the loss of which is known. The constant k, is evaluated by this method in the experimental part of this paper, for the quadrant electrometer used in the tests.

It is also evident from equations (**15**) and (**16**) that k may be eliminated if we take the means of two sets of

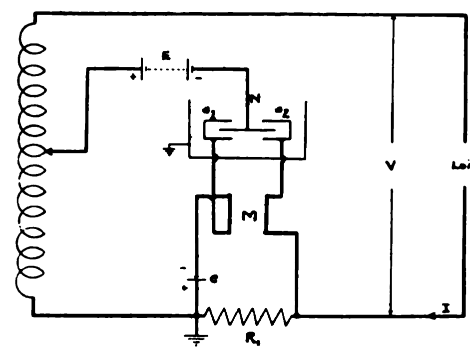

Fig. 7—Fractional Voltage on Needle for Zero Method C Commutator Vertical

readings as described under method A, the first being taken with the polarities of the batteries as shown in Fig. 6, and the second with the batteries reversed.

We can simplify the equations for the purpose of calculation by writing them in a slightly different form. For example we can write equation (**15**) in the form of equation (**17**).

$$I\,V\cos\varphi + \frac{I^2\,R_1}{2} = \frac{(E-k)\,e}{R_1} \qquad (\mathbf{17})$$

Zero Method—Fractional Voltage on the Needle. Any one of the three methods described may be used with fractional voltage applied to the needle. Method C requires the least amount of calculation and is probably

the simplest method to use, therefore, it will be the only method discussed with fractional needle voltage. The connections are shown in Figs. 7 and 8.

With the commutator vertical as in Fig. 7, we have

$$V_0 = \frac{v + i R_1}{n} - E$$

$$V_1 = - e$$

$$V_2 = i R_1$$

and for Fig. 8

$$V_0 = \frac{v + i R_1}{n} - E$$

$$V_1 = i R_1 + e$$

$$V_2 = 0$$

where n equals the factor by which the a-c. voltage applied to the needle must be multiplied to give the total alternating voltage of the circuit.

Substituting these values in the general equation (**3**) of the electrometer, and solving, we obtain (**18**) the derivation of which is similar to that of equations (**15**) and (**16**)

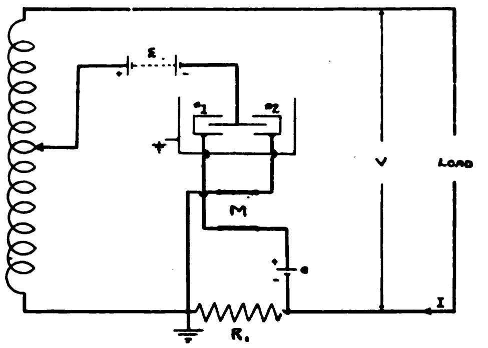

FIG. 8—FRACTIONAL VOLTAGE ON NEEDLE—ZERO METHOD C COMMUTATOR HORIZONTAL

which are derived in the mathematical part of the paper

$$I\, V \cos \varphi + \frac{2 - n}{2} I^2 R_1 = n \frac{(E - k)\, e}{R_1} \qquad (18)$$

It is evident from a study of equation (**18**) that if n equals 1, it reduces to equation (**17**).

The correctness of equation (**18**) was also verified experimentally.

II. EXPERIMENTAL

The electrometer used in these tests was a Dolezalek quadrant electrometer.

Determination of the Constant, k. The constant, $k = \frac{c_1}{b_1}$, was determined by using a resistance load in the circuit of Fig. 6. The load consisted of a non-inductive resistance, R_0, whose value was 260916 ohms. Method C was used in determining the constant. The applied a-c. voltage was 201 volts at 60 cycles. The continuous voltage, E, that is inserted in the needle lead, was made up of three 22.5-volt Radio B batteries. Its value was measured with a 150-volt d-c. voltmeter. The continuous voltage that is inserted in the quadrant circuit, was taken from a six-volt storage battery connected to a potentiometer rheostat. The value of the continuous quadrant voltage, e, that is actually used in the circuit was measured by a 3/15/150-volt Weston Laboratory Standard d-c. voltmeter. The voltmeters used in the experimental work were checked against a Weston Standard Cell.

The quadrant electrometer was set up and adjusted until its electrical and mechanical zeros coincided. Then the load was applied and readings were taken at different values of R_1, the non-inductive resistance across which the quadrants are connected. Two readings of e were made at each setting of R_1; e_1 with the commutator in a vertical position and e_2 with the commutator in the horizontal position. The value of e was adjusted each time until the deflection was reduced to zero, and e_1 is the value of the quadrant voltage for zero deflection and the commutator vertical, and e_2 for zero deflection and the commutator horizontal.

The readings are given in Table I below:

TABLE I
ZERO METHOD C—RESISTANCE LOAD R_0

A-C. Supply voltage	Load R_0-ohms	R_1 ohms	E volts	Commutator $\|\|$ e_1-volts	$=$ e_2-volts	Average e volts
201	260916	500	69.4	1.128	1.121	1.1245
		1000	69.45	2.284	2.208	2.246

		1000	69.35	2.284	2.205	2.245
		2000	69.4	4.62	4.32	4.47

The value of the alternating current in the circuit and the total loss measured by the electrometer, which in this case is the loss in the load R_0 plus one-half the loss in R_1, were calculated for each set of readings. From these results the constant, k, was determined from equation (**15**) as shown in Table II. Its value was found to equal 0.8154.

Experimental Proof of Zero Method A. Experimental proof of the correctness of the theory involved in zero method A and of equations (**8**) and (**9**) that apply to

this method was obtained by using a resistance load as described in the determination of the electrometer constant k. The connections shown in Fig. 2 were used in this test, except that the polarity of the two batteries are opposite to that shown in the figure. Therefore, equation (9) applies to this test.

The results of the test are given in Table III. The watts consumed by the load R_0 and the loss in the resistance R_1 were calculated from the values used in the circuit as was the case in Table II.

A comparison of the results given in the last two columns of Table III shows good agreement between the calculated watts and the watts as measured by the electrometer.

As stated in the theoretical part of the paper, the constant k need not be determined if two sets of readings are taken, one with the battery polarities as shown in Fig. 2, and the other with the polarities reversed. In order to check this conclusion from the theory a number of sets of readings were taken at different values of R_1, using the resistance load, R_0, of 260916 ohms. The results for two sets of these readings are given in Table IV.

A comparison of the average watts as measured by the electrometer with the calculated watts shows an excellent agreement, and proves that this method may be used if desired to determine watts consumed by a load. A disadvantage of this method lies in the fact that four readings are needed.

In most cases, it is better to determine the electrometer constant k and calculate the power consumed by the load from a single set of readings.

The experimental results prove that Method A and the equations that apply are correct.

Experimental Proof of Zero Method B. The experimental proof of the correctness of the theory of zero Method B and of equations (12) and (13) was also

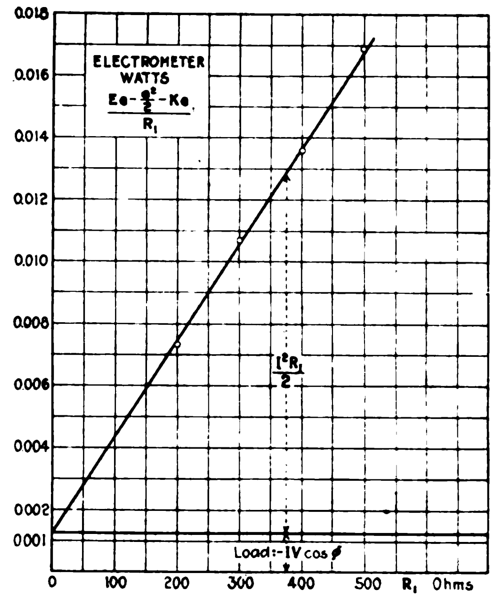

FIG. 9—CAPACITY LOAD (ZERO B METHOD)

obtained using a resistance load, R_0. The connections used are those given in Fig. 3, and equation (12) applies to this test.

The results of this test are given in Table V and a study of the last two columns show that there is a good

agreement between the calculated watts and the watts as measured by the electrometer.

The experimental results prove the correctness of the theory involved in Method B.

Experimental Proof of Zero Method C. Experimental proof of zero method C follows from the results of the tests of methods A and B and also from the measurements made to determine the value of the constant k which are given in Tables I and II. Therefore, no further readings will be given for the measurement by method C of the power consumed in a resistance load.

Capacity Load. Tests were made to determine the loss in a condenser using zero methods A, B and C. The condenser used in these tests was a 1/10 microfarad standard mica condenser. The results obtained by the three methods checked closely, and are given here for methods B and C only.

Data taken by method B, using the connections of Fig. 2, are given in Table VI.

TABLE V
ZERO METHOD B, RESISTANCE LOAD R_0

A-C. Supply voltage	Load R_0 ohms	R_1 ohms	E volts	Commutator $\parallel$ e_1 volts	Commutator $=$ e_2 volts	Average e volts	Calculated watts $I^2\left(R_0+\frac{R_1}{2}\right)$	Electrometer watts $\frac{Ee+\frac{e^2}{2}-ke}{R_1}$
201	260916	500	69.35	1.12	1.111	1.115	0.1544	0.1541
		1000		2.208	2.20	2.204	0.1540	0.1535
		2000		4.33	4.31	4.32	0.1531	0.1527
		1000		2.214	2.192	2.203	0.1540	0.1535

In order to eliminate the correction term $\frac{I^2 R_1}{2}$ the electrometer[4] watts are plotted against the values of R_1 as abscissas. These points lie on a straight line as shown in Fig. 9. If this line is extended to the ordinate axis it will cut the axis at a value equal to the watts lost in the load.[5] From Fig. 9 we see that the loss in the condenser is 0.00125 watts.

A test was made with the same condenser using method C. In this test the loss in the condenser was calculated from the formula

$$I\,V\cos\varphi = \frac{(E-k)\,e}{R_1} - \frac{I^2 R_1}{2}$$

The current I equaled 0.00754 amperes as calculated from the constants of the circuit. The readings are given in Table VII and the average loss was found to equal 0.00127 watts and the power factor was 0.085 per cent. The results of the tests by the two methods are in close agreement.

A-C. Applied Voltage = 62 Volts at 60 Cycles

Method	R_1 ohms	E volts	Average e volts	$E\,e$	$\frac{e^2}{2}$	$k\,e$	Electrometer reading. (Loss in Inductance plus $\frac{I^2 R_1}{2}$)
A	200	69	1.707	117.8	−1.456	−1.392	0.575
B	200		1.6695	115.2	+1.393	−1.361	0.576
C	200		1.6955	117.0	0	−1.382	0.578

Inductive Load. Readings were taken with an inductive load using all three zero methods. The load consisted of an inductance of about 8. henrys and 1650 ohms resistance.

In this test the polarity of the batteries was such that equation (**8**) applies to the results of method A; equation (**12**) to method B; and equation (**15**) to method C.

The results are given in Table VIII and the loss as calculated includes half the loss in the shunt resistance R_1, which was the same for each method.

A comparison of the results of the three methods given in the last column of Table VIII shows that they give the same loss for the circuit within $\pm$ 0.3 per cent.

The experimental results prove conclusively the correctness of the equations as derived, and that the methods may be employed to measure the loss at any value of the power factor leading or lagging.

III. Mathmetical

Derivation of Equation (**8**) *Method A.* Equation (**8**) is obtained by substituting the instantaneous values of the potentials applied to the needle and quadrants in the general equation (**3**) of the electrometer. The electrometer reads the integral of these voltages over a complete period T.

With the commutator vertical in Fig. 2 we have

$$V_0 = v + i R_1 - E$$
$$V_1 = - e_1$$
$$V_2 = i R_1$$

where $v = \sqrt{2} V \sin \omega t$

and $i = \sqrt{2} I \sin (\omega t \pm \varphi)$

Substituting these values and integrating over a complete period, we get the values of the terms in equation (**3**) as follows:

$$- \frac{b_1}{2} V_1^2 = - \frac{b_1}{2} e_1^2$$

$$+ \frac{b_1}{2} V_2^2 = + \frac{b_1}{2} \frac{1}{T} \int_0^T R_1^2 . 2 I^2 \sin^2 (\omega t \pm \varphi)\, dt = + \frac{b_1}{2} I^2 R_1^2$$

$$+ b_1 V_0 V_1 = + b_1 \frac{1}{T} \int_0^T [\sqrt{2} V \sin \omega t + R_1 \sqrt{2} I \sin (\omega t \pm \varphi) - E][- e_1]\, dt = + b_1 E e_1$$

$$- b_1 V_0 V_2 = - b_1 \frac{1}{T} \int_0^T [\sqrt{2} V \sin \omega t + R_1 \sqrt{2} I \sin (\omega t \pm \varphi) - E][R_1 \sqrt{2} I \sin (\omega t \pm \varphi)]\, dt = - b_1 (R_1 I V \cos \varphi + I^2 R_1^2)$$

$$+ c_0 V_0 = c_2 \frac{1}{T} \int_0^T [\sqrt{2} V \sin \omega t + R_1 \sqrt{2} I \sin (\omega t \pm \varphi) - E]\, dt = - c_0 E$$

$$+ c_1 V_1 = - c_1 e_1$$

$$- c_1 V_2 = - c_2 \frac{1}{T} \int_0^T \sqrt{2} V \sin \omega t\, dt = 0$$

With the commutator horizontal the values of V_1 and V_2 change as stated under zero method A, and by substituting these new values of V_1 and V_2 in the terms of equation (**3**) and integrating we may determine the values of these terms for the commutator horizontal.

The signs and the values of the terms in equation (**3**) for the two positions of the commutator are given below in (**4**) and (**5**).

Pos of Comm.	Equa. No.	VALUE OF TERMS				
	(3)	$-\frac{b_1}{2} V_1^2 + \frac{b_1}{2} V_2^2$	$+ b_1 V_0 V_1$	$- b_1 V_0 V_2$	$+ c_0 V_0 + c_1 V_1 - c_1 V_2$	$= (1 + R V_0^2)\, \theta$
$\vert\vert$	(4)	$-\frac{b_1}{2} e_1^2 + \frac{b_1}{2} I^2 R_1^2$	$+ b_1 E e_1$	$- b_1 (R_1 I V \cos \varphi + I^2 R_1^2)$	$- c_0 E - c_1 e_1 - 0$	$= (1 + R V_0^2)\, \alpha$
$=$	(5)	$-\frac{b_1}{2} I^2 R_1^2 + \frac{b_1}{2} e_2^2$	$+ b_1 (R_1 I V \cos \varphi + I^2 R_1^2)$	$- b_1 E e_2$	$- c_0 E - 0 + c_1 e_2$	$= (1 + R V_0^2)\, \beta$

Taking the algebraic sum of equations (**4**) and (**5**) we get equation (**6**).

$$(1 + R V_0^2)(\beta - \alpha) = 2 b_1 R_1 I V \cos \varphi + b_1 I^2 R_1^2 - b_1 E (e_1 + e_2) + \frac{b_1}{2} (e_1^2 + e_2^2) + c_1 (e_1 + e_2) \qquad (6)$$

The experimental results show that e_1 and e_2 are nearly equal and that we may write $e = \frac{e_1 + e_2}{2}$ without introducing any appreciable error. Since the deflections α and β are each zero, we may write equation (**6**) equal to zero and solve for the power consumed by the load.

$$I V \cos \varphi + \frac{I^2 R_1}{2} = \frac{E e - \frac{e^2}{2}}{R_1} - \frac{c_1}{b_1} \frac{e}{R_1} \qquad (7)$$

Equation (**7**) contains two of the electrometer constants b_1 and c_1, which may be combined as previously described, in a single constant $k = \frac{c_1}{b_1}$. Under these

conditions we may write equation (**7**) in the form

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e - \dfrac{e^2}{2}}{R_1} - k\frac{e}{R_1} \qquad (8)$$

If we reverse the polarities of the two batteries, E and e, and proceed as in determining equation (**8**) we find that the power consumed by the load is given by equation (**9**).

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e - \dfrac{e^2}{2}}{R_1} + k\frac{e}{R_1} \qquad (9)$$

Derivation of Equation (**12**), *Method B.* The relations giving the power consumed by the load with the connections as in Fig. 3, method B, are derived from equation (**3**) in a manner similar to that used in finding (**8**).

Pos. of Comm.	Equa. No.	VALUE OF TERMS
	(3)	$-\frac{b_1}{2}V_1^2 + \frac{b_1}{2}V_2^2 + b_1 V_0 V_1 - b\ V_0 V_2 + c_0 V_0 + C_1 V_1 - c_2 V_2 \quad = (1 + R\,V_0^2)\,\theta$
||	(10)	$0 + \frac{b_1}{2}(I^2 R_1^2 + e_1^2) + 0 - b_1(R_1 I\,V\cos\varphi + I^2 R_1^2 - E\,e_1) - c_0 E - 0 - c_1 e_1 \quad = (1 + R\,V_0^2)\,\alpha$
=	(11)	$-\frac{b_1}{2}(I^2 R_1^2 + e_2^2) + 0 + b_1(R_1 I\,V\cos\varphi + I^2 R_1^2 - E\,e_2) - 0 - c_0 E + c_1 e_2 - 0 \quad = (1 + R\,V_0^2)\,\beta$

Taking the algebraic sum of equations (**10**) and (**11**) and solving for the power consumed by the load we obtain equation (**12**) for connection B.

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E + \dfrac{e^2}{2}}{R_1} - k\frac{e}{R_1} \qquad (12)$$

Derivation of Equation (**15**), *Method C.* Method C is a combination of methods A and B, as stated above. With the commutator vertical equation (**4**) of method A, holds and with the commutator horizontal we have equation (**10**) of method B. Taking the algebraic sum of equations (**10**) and (**4**) we obtain equation (**14**).

$$(1 + R\,V_0^2)(\beta - \alpha) = 2\,b_1 R_1 I\,V\cos\varphi$$

$$+ b_1 I^2 R_1^2 - b_1 E(e_1 + e_2) + \frac{b_1}{2}(e_1 - e_2) + c_1(e_1 + e_2) = 0 \qquad (14)$$

Assuming that e_1 is very nearly equal to e_2 the fourth term of the equation becomes negligible and we can write that the power consumed by the load is

$$I\,V\cos\varphi + \frac{I^2 R_1}{2} = \frac{E\,e}{R_1} - k\frac{e}{R_1} \qquad (15)$$

The Correction Term, $k\dfrac{e}{R_1}$. Several methods are possible for eliminating the correction term, $k\dfrac{e}{R_1}$ in addition to those mentioned in the paper. The elimination of this term may be accomplished in method C, for example, by reversing the polarity of the battery in the needle circuit, instead of reversing e as described under this method. This, however, introduces another correction term in the equation which involves E and is, therefore, not to be recommended.

The importance of the correction term, $k\dfrac{e}{R_1}$, can be reduced by use of larger values of the needle battery E. This reduces the value of e needed to balance the torque of the a-c. voltages.

IV. Errors

The sources of error present in any quadrant electrometer have already been ably discussed in an Institute paper[2]. The more important are:

1. A study of the diagram of connections of the quadrant electrometer shows that the electrostatic capacity formed by the two quadrant pairs and their leads is in parallel with the non-inductive resistance R_1. Therefore, the drop across R_1 and this condenser in parallel with it will not be in phase with the current. This error is naturally greater the higher the value of R_1. Taking this into account we find that the equation[6] for method C is as follows:

$$I\,V\cos\varphi + \frac{2 - n}{2} I^2 R_1 + I\,(\omega\,c_1 R_1)\,V\sin\varphi$$

$$= \frac{n\,(E - k)\,e}{R_1} \qquad (19)$$

where c_1 is the electrostatic capacity of the quadrant pair circuit in farads.

In measuring the loss in the 1/10 microfarad condenser by methods B and C it was found possible to work with a value of R_1 as low as 200 ohms and still obtain good accuracy. Tests of this same condenser by the deflection method require a value of R_1 of the order of 1000 ohms to obtain satisfactory deflections. It is evident that the error introduced by the capacity of the quadrants depends upon the value of R_1, and that it is reduced in amount by the use of this zero method.

2. Further study of the quadrant electrometer circuit shows that the charging current I_1 from the

needle to the high quadrant flows through R_1 in addition to the load current, I.

This source of error is very small in low voltage electrometers and may usually be neglected.

3. The theory of the electrometer is based upon the assumption that the resistance of the needle circuit is zero, and the needle charging current flows through a pure capacity.

The use of the battery, E, in the needle circuit introduces a resistance, but its value in our tests was so small compared to the capacitance of the needle circuit that its effect was negligible.

4. If fractional voltage is applied to the electrometer needle, the e. m. f. of the portion of the transformer winding to which the needle circuit is attached, may differ in phase from the total voltage in the circuit. This source of error may become very important at low values of the power factor of the load, and in such cases must be corrected for[2].

General Theory of the Auto-Transformer

BY WALTER L. UPSON[1]

Member, A. I. E E.

Synopsis.—*The method of complex quantities lends itself admirably to the development of general theory of the auto-transformer. As worked out, in this instance, it is found desirable to maintain the actual voltage ratio instead of reducing values to an equivalent 1:1 basis. Examples are given of calculations by this method, and also comparison is made with calculated performance of the two-circuit transformer. Certain inherent peculiarities of the auto-transformer are pointed out, being due to the effects of internal resistance and reactance.*

Part II is an application of the theory to transformers without iron and a number of interesting conclusions are brought out.

* * * * *

An auto-transformer may be represented as a single winding on an iron core, as illustrated in Fig. 1. Primary voltage, E_1, is impressed on the winding, and secondary voltage, E_2, is obtained by suitable taps. The primary current, I_1, flows in a portion of the winding of t_1 turns. The rest of the winding carries current, I_2, which is the resultant of the current I_1 and the load current I_L, and it consists of t_2 turns. The total turns of the entire winding are $t = t_1 + t_2$. Ratio of transformation is given by

$$f = \frac{t}{t_2} = \frac{t_1 + t_2}{t_2} = \frac{E_1}{E_2}$$

at no load.

Resistances of windings t_1 and t_2 are r_1 and r_2 respectively, and reactances are x_1 and x_2. Fig. 2 illustrates the vector relations which exist. We may begin with the flux ϕ, drawn vertically upward. This is produced by magnetizing current i_m in phase with it. Ninety deg. ahead of the flux is the core-loss current i_c. i_m and i_c vectorially added give the exciting current I_x. Ninety deg. behind the flux is the e. m. f., e_i, induced in the turns t_2. The load current $I_L = i_L + j\, i_L'$ is drawn at any desired angle with reference to e_i.

So far, the vector relations are similar to those of the ordinary two-circuit, constant potential transformer. But in the case of the auto-transformer a departure from similarity occurs at this point. This departure is due to two causes; (1) the current in the turns t_2 is not the load current, and (2) the vectors are given actual values and are not reduced to a 1 : 1 equivalent

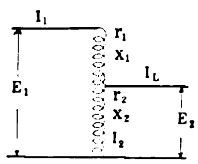

Fig. 1

ratio. This latter consideration is not awkward on account of the fact that auto-transformer ratios do not usually depart very far from 1 : 1, being in that respect quite different from two-circuit transformers.

We now draw $-f\,e_i$, 180 deg. ahead of e_i, and this is that portion of the impressed voltage required to produce e_i in t_2. Similarly, $-\dfrac{I_L}{f}$ is the load component of primary current, 180 deg. ahead of I_L.

1. Professor of Electrical Engineering, Washington University, St. Louis, Mo.

Presented at the Annual Convention of the A. I. E. E., at White Sulphur Springs, W. Va., June 21-25, 1926.

The entire primary current I_1 is the vector sum of I_x and $-\frac{I_L}{f}$. The secondary current, I_2 in t_2, is the vector sum of I_1 and I_L. Secondary voltage, E_2, is obtained by subtracting from e_i the $I_2 r_2$ and $I_2 X_2$ drops in turns t_2.

Primary voltage, E_1, is obtained by adding to $-f e_i$ the $I_1 r_1$, $I_1 x_1$, $I_2 r_2$, and $I_2 x_2$ drops, all operations being, of course, vectorial.

The method of complex quantities lends itself readily to this procedure. It is convenient to start with e_i as the zero vector, however, rather than with E_1 or E_2. This makes the use of the method very simple. Certain difficulties which are introduced may be readily provided for. The chief difficulty is in ascribing to the load current a definite, desired phase angle with respect to E_2, as the components of I_L are given with respect to the zero vector e_i. This and other points will appear in the case of examples cited.

The vector equations are as follows:

$$\dot{I}_1 = \dot{I}_x - \frac{\dot{I}_L}{f} = -\frac{i_L}{f} + i_c + j\left(i_m - \frac{i_L'}{f}\right)$$
$$= i_1 + j\, i_1'$$
$$\dot{I}_2 = \dot{I}_1 + \dot{I}_L = i_1 + i_L + j\,(i_1' + i_L') = i_2 + j\, i_2'$$
$$\dot{E}_2 = e_i - \dot{I}_2 z_2 = e_i - i_2 r_2 + i_2' x_2 - j\,(i_2 x_2 + i_2' r_2)$$
$$= e_2 + j\, e_2'$$

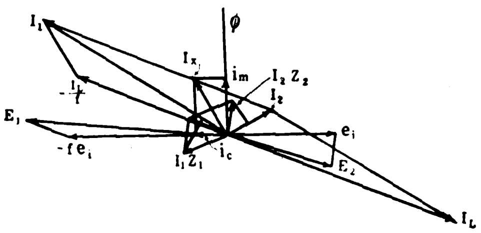

Fig. 2

$$\dot{E}_1 = -f e_i + \dot{I}_1 z_1 + \dot{I}_2 z_2$$
$$= -f e_i + i_1 r_1 - i_1 x_1' + i_2 r_2 - i_2' x_2$$
$$+ j\,(i_1 x_1 + i_1' r_1 + i_2 x_2 + i_2' r_2) = e_1 + j\, e_1'$$

Power input is $P_1 = e_1 i_1 + e_1' i_1'$

Power output is $P_2 = e_2 i_L + e_2' i_L'$

Efficiency is $\eta = \frac{P_2}{P_1}$

Primary power factor is $P f_1 = \frac{P_1}{E_1 I_1}$

Load power factor is $P f_2 = \frac{P_2}{E_2 I_L}$

Regulation is given by the equation

$$\text{Per cent regulation} = \frac{E_2 \text{ at no load} - E_2}{E_2}$$

when the primary impressed voltage is constant. All the above relations, however, are based on an assumed constant induced voltage, e_i, and consequently it would seem, judging by common experience with the two-circuit transformer, that the primary voltage will not be the same at load and no load. It is advisable, then, to determine both E_2 and E_1 for the condition of no load always keeping e_i constant.

The value of E_2 thus obtained should be multiplied by the ratio

$$\frac{E_1 \text{ at load}}{E_1 \text{ at no load}}$$

This reduces E_2 to the value it would have at constant impressed primary voltage. Carrying out this process, equations for the case of $\dot{I}_L = 0$ are as follows:

$$\dot{I}_1 = i_c + j\, i_m = \dot{I}_2$$
$$\dot{E}_2 = e_i - i_c z_2 - j\, i_m z_2 = e_i - i_c r_2 + i_m x_2$$
$$- j\,(i_c x_2 + i_m r_2)$$
$$= e_2 + j\, e_2'$$
$$\dot{E}_1 = -f e_i + i_c (z_1 + z_2) + j\, i_m (z_1 + z_2)$$
$$= -f e_i + i_c (r_1 + r_2) + j\, i_c (x_1 + x_2)$$
$$- i_m (x_1 + x_2) + j\, i_m (r_1 + r_2)$$
$$= -f e_i + i_c r_1 + i_c r_2 - i_m x_1 - i_m x_2$$
$$+ j\,(i_c x_1 + i_c x_2 + i_m r_1 + i_m r_2) = e_1 + j\, e_1'$$

$$\text{Per cent regulation} = \frac{K\, E_2 \text{ (at no load)} - E_2 \text{ (at load)}}{E_2 \text{ (at load)}}$$

where

$$K = \frac{E_1 \text{ at load}}{E_1 \text{ at no load}}$$

The value of this constant is either exactly unity or very near to it in practical cases. The difference in voltage between E_1 at load and E_1 at no load is given by the equation

$$\dot{E}_1 \text{ (at load)} - \dot{E}_1 \text{ (at no load)}$$
$$= i_L\left(-\frac{r}{f} + r_2\right) + i_L'\left(\frac{x}{f} - x_2\right)$$
$$+ j\left[i_L\left(-\frac{x}{f} + x_2\right) + i_L'\left(-\frac{r}{f} + r_2\right)\right]$$

where r and x are total resistance $r_1 + r_2$, and total leakage reactance $x_1 + x_2$, respectively.

This difference reduces to zero in many cases, for example, when $f = 2$, $r_1 = r_2$, and $x_1 = x_2$, which is the case with a uniformly wound coil tapped at its middle point.

Thus, in this case, per cent regulation is simply

$$\frac{E_2 \text{ (at no load)} - E_2 \text{ (at load)}}{E_2 \text{ (at load)}}$$

As an illustration of the whole method we will give

values for the calculation of a 50-kva., 60-cycle, 220/110-volt auto-transformer.

Constants, on percentage basis, are as follows:

Induced voltage $= e_i = 1$

$$r_1 = r_2 = 0.01$$
$$x_1 = x_2 = 0.02$$
$$i_m = 0.025$$
$$i_c = -0.01$$
$$f = 2 = \text{ratio of transformation}$$
$$\dot{I}_L = 1 + j\,0$$

Substituting these values into the above equations we get:

$$\dot{I}_1 = -0.51 + j\,0.025$$
$$\dot{I}_2 = 0.49 + j\,0.025$$
$$\dot{E}_2 = 0.9956 - j\,0.01005$$
$$\dot{E}_1 = -2.0012 + j\,0.0001$$
$$\dot{P}_1 = \text{power input} = 1.0206$$
$$\dot{P}_2 = \text{power output} = 0.9956$$

Efficiency $= 0.974$

Primary power factor $= 0.997$

$$\text{Power factor of load} = \frac{0.9956}{0.9956} = 1$$

To obtain regulation, we have the following values for the condition of zero loading:

$$\dot{I}_1 = \dot{I}_2 = -0.01 + j\,0.025$$
$$\dot{E}_2 = 1.0006 - j\,0.00005$$
$$\dot{E}_1 = -2.0012 + j\,0.0001$$

$$K = \frac{E_1 \text{ at load}}{E_1 \text{ at no load}} = \frac{2.0012}{2.0012} = 1$$

Therefore,

$$\text{Regulation} = \frac{1.0006 - 0.9956}{0.9956} = \frac{0.005}{0.9956} = 0.005$$

This transformer may be considered as a 1 : 1 two-circuit transformer according to the usual method of calculation. Table I gives comparative performance as auto-transformer and as two-circuit transformer. As transformer of the latter type the constants are:

$$e_i = 1, r_1 = r_2 = 0.01, x_1 = x_2 = 0.02, i_m = 0.05$$
$$i_c = 0.02, \dot{I}_L = 1 + j\,0$$

Values of the components of exciting current are seen to be twice those of the auto-transformer. In general, in order that flux and core-loss shall be the same in the two transformers, it is necessary to divide the values for exciting current of the two-circuit machine by the ratio of transformation of the auto-transformer.

TABLE I

	Two-Circuit Trans.	Auto-Trans.
Load Current	$1 + j\,0$	$1 + j\,0$
Efficiency	0.963	0.974
Regulation	0.022	0.005

Comparative efficiencies are as we should expect. Due to reduction in copper losses the auto-transformer shows superiority. In regulation, however, its superiority is far more marked, due largely to the fact that the impedance drop in the secondary winding has a negative effect and tends to raise the secondary voltage instead of lowering it.

Under short circuit, the exciting current ceases to flow in the secondary turns, and is diverted entirely into the short circuit. The short-circuit current may be considered as made up of three parts, (1) that supplied by the secondary turns, which is the induced voltage divided by secondary impedance, (2) the load component of the primary which is equal to (1) multiplied by $\frac{t_2}{t_1}$, and (3) the exciting current, which, at short circuit, is equal to $\frac{t}{t_1}$ times I_x at no load. In the case considered, in which $f = 2$, it is:

$$\dot{I}_2 = \frac{e_i}{r_2 + j\,x_2} = \frac{e_i\,r_2}{z_2^2} - j\,\frac{e_i\,x_2}{z_2^2} = 20 - j\,40$$

$$\dot{I}_{sh.\,cir} = 2\,\dot{I}_2 + 2\,\dot{I}_x = 40.02 - j\,80.05$$

where $\dot{I}_x$ is taken as flowing in the same direction as $\dot{I}_2$; that is, $\dot{I}_x = 0.01 - j\,0.025$.

Total short-circuit current is then 89, approximately.

When operated as a two-circuit transformer, the short-circuit current is 22.3, or one-fourth as much as that of the auto-transformer.

It is interesting to notice the conditions as relating to the exciting current with various loadings of the transformer. At no load, its value is the same in both parts of the winding, t_1 and t_2. Exciting ampere-turns are $I_x\,t$. As the load is increased the load impedance offers a path for the exciting current in parallel with t_2, thereby causing a slight increase in the exciting current which flows in t_1 and a slight decrease in that which flows in t_2. No account is taken of this variation for ordinary loading, as it is insignificant. The total exciting ampere-turns remain constant for all loads, producing constant mutual flux and constant induced voltage in the secondary. Voltage induced in t_1 must also be constant. At short circuit, we have maximum exciting current in t_1 and zero exciting current in t_2. In a 2 : 1 transformer the value of this current in t_1 is $2\,I_x$, where I_x is the no-load exciting current.

The total $I_1\,Z_1$ drop in t_1 is approximately equal to e_i, at short circuit, so that the impressed voltage $E_1 = 2\,e_i$. This relationship is similar to that which exists in a two-circuit transformer, where, at short-circuit, the voltage drop in the primary is approximately equal to the induced voltage. In this case, however, the equality is brought about by reduction in the value of the induced voltage, which, at short circuit, is only half its no-load value.

Part II

AUTO-TRANSFORMERS WITHOUT IRON[2]

Air-core transformers are in general at a disadvantage owing to the fact that their magnetic fields are produced in a medium of unit permeability. Absence of iron, however, offers some compensating advantages, namely, absence of core-loss and exciting current distortion, and saving in cost of iron and in cost of construction. At sixty cycles, these advantages are far out-weighed by the disadvantages in performance as compared with two-circuit transformers. At higher frequencies the situation becomes more and more favorable for the air-core transformers, until at radio frequencies the use of iron is inadmissible.

With auto-transformers the case is distinctly more favorable for the air-cores at lower frequencies. The same theory applies as with iron-core transformers except that the core-loss component of the exciting current drops out. The constants are, of course, very different and it will be of interest to give some values and results that may be expected in practise. An air-core auto-transformer should be wound for maximum self-inductance of the entire winding and maximum mutual inductance of the two parts, that is, of t_1 and t_2. This maximum mutual inductance will, of course, mean minimum leakage reactance.

An auto-transformer may be designed from either of two points of view as respects operation. It may be designed either to operate at a fixed ratio of transformation or as a compensator with taps to give different voltages over a considerable range of ratio.

Table II gives comparative results to be expected from an air-core compensator with three taps giving voltage ratios of 4 : 3, 4 : 2, and 4 : 1. The same voltage is impressed on the primary in each case, and the same load current is assumed. The constants for the three cases are given in the preceding table.

TABLE II

	A	B	C
Transformer ratio	4:3	4:2	4:1
Primary resistance, r_1	0.01	0.02	0.03
Secondary resistance, r_2	0.03	0.02	0.01
Primary reactance, x_1	0.1	0.2	0.3
Secondary reactance, x_2	0.3	0.2	0.1
Magnetizing current	0.3	0.3	0.3
Load current	$1-j\,.1$	$1-j\,.1$	$1-j\,.1$
Induced voltage, e_i	1.5	1	0.5
Primary voltage, E_1	2.12	2.12	2.12
Primary current, I_1	0.838	0.61	0.41
Power input	1.5945	1.0642	0.5349
Secondary voltage, E_2	1.575	1.047	0.52
Secondary current, I_2	0.372	0.559	0.783
Power output	1.5833	1.05	0.523
Efficiency	0.992	0.986	0.979
Primary power factor	0.896	0.822	0.614
Load power factor	1 approx	1.	1.
Secondary no-load voltage	1.59	1.06	0.53
Primary no-load voltage	2.12	2.12	2.12
Per cent regulation	0.0095	0.0124	0.0192

2. A paper on this subject was presented by the author before Section M of the American Association for the Advancement of Science, December 1916, but was preliminary in character and never has been published.

It is to be noted that for low ratio, the primary turns are relatively heavily loaded while the secondary turns are lightly loaded.

With high ratio, the opposite is true. Therefore, if the transformer is to be operated continuously at a fixed ratio, the cross section of wire for primary and secondary should be proportioned to the respective currents to be carried. For a 2 : 1 ratio, the wire should be the same in cross-section for both windings.

In the above table, we see, as we saw with the case of the iron-core transformer, that the impressed voltage is constant regardless of load. The effect of $r\,I$ drop in the primary is exactly neutralized by the $r\,I$ drop in the secondary except for the small and constant drop due to the exciting current. This balance of drops does not obtain if the resistances and reactances are not so proportioned as to accomplish it, but there is always a tendency in that direction. To illustrate this situation we will make comparison of two auto-transformers with the following constants: ratio of transformation, 5 : 4; exciting current, 0.3; load current, $I_L = 1 - j\,.2$; induced voltage, 1; total resistance, 0.04; total reactance, 0.4. The resistances and reactances of the two transformers are differently distributed between primary and secondary, as follows:

TABLE III

	D	E
Primary resistance, r_1	0.02	0.003
Primary reactance, x_1	0.2	0.03
Secondary resistance, r_2	0.02	0.037
Secondary reactance, x_2	0.2	0.37
Primary current, I_1	0.922	0.922
Secondary current, I_2	0.328	0.328
Primary voltage, E_1	1.41	1.358
Secondary voltage, E_2	1.05	1.093
No-load primary voltage	1.37	1.37
No-load secondary voltage	1.06	1.115
Regulation constant, K	1.03	0.99
Per cent regulation	0.038	0.011

Transformer E is seen to operate at nearly constant impressed voltage, and it is this one in which the wire has been proportioned to the currents to be carried.

Certain inherent features of the performance of air-core transformers are of interest. They are due to the fact that the magnetic field is in a medium of constant permeability and consequently all effects due to magnetic saturation are automatically eliminated.

1. Thus, if the characteristics of an air-core transformer are known for one value of impressed voltage, they may be obtained for any other value. For example, let $E_1 = 100$, and let maximum efficiency occur with a load of 10 amperes, and, let us say, 950

watts. If, now, the voltage is raised to 110, maximum efficiency will occur at $\frac{110}{100}$ times $10 = 11$ amperes, and $\left(\frac{110}{100}\right)^2$ times $950 = 1150$ watts. One efficiency curve applies to the transformer, whatever the impressed voltage, provided the scale of amperes and watts is changed in the proper ratio.

2. To obtain maximum capacity, it is only necessary to impress such a voltage on the primary as will correspond with maximum permissible current in the windings at full load, or, conversely, the windings of a transformer may be so chosen as to carry maximum permissible current at full load with any specified impressed voltage.

3. Regulation of an air-core auto-transformer is more affected by leakage reactance than by resistance, when operating at high power factor. This fact is quite apparent from a study of the vector diagram. The primary $I\,x$ drop is almost directly in phase with the impressed voltage, instead of being at right angles to it, giving nearly the worst condition for regulation. To offset this, however, the secondary $I\,x$ drop, while considerably out of phase with E_2, is generally so directed as to assist regulation, partially neutralizing the bad effects of primary reactance.

(4). Power factor of the air-core transformer is generally much poorer than that of the iron-core type because the magnetizing current is a comparatively large out-of-phase component of the primary current. This large magnetizing current is not altogether undesirable, however. It causes a greater lead of I_2 with respect to E_2 and reduces the amount of I_2 without proportionally increasing I_1.

In general, it may be said that the air-core auto-transformer offers possibilities at 60 cycles. At higher frequencies, such as 120 or 180 cycles, it becomes of decidedly more than theoretical interest.

Variable Armature Leakage Reactance in Salient-Pole Synchronous Machines

BY VLADIMIR KARAPETOFF[1]

Fellow, A. I. E. E.

Synopsis.—*The electrical performance characteristics of a polyphase synchronous machine, that is, its voltage-current relations under load, depend essentially upon the nature and the extent of the magnetomotive forces of the armature currents. Broadly speaking, the effect of these magnetomotive forces is two-fold; i. e., (a) they oppose and distort the field magnetomotive force and (b) they create leakage fields linked with the armature conductors. The first influence is known as the armature reaction, and the second as the armature reactance. More specifically, in a machine with salient poles, the armature reaction may be resolved for purposes of computation into the direct reaction (along the center lines of the poles) and the transverse reaction, midway between the poles. In polyphase machines of usual proportions, the armature leakage reactance, x, usually plays a secondary role, and for most purposes is assumed to be constant and independent of the power factor of the load. The vector of the reactive drop, Ix, is simply drawn in a leading time quadrature with the current I.*

However, in machines with considerable armature reactance, or where higher accuracy is required, the assumption of a constant x leads to noticeable discrepancies between the computed and observed data. This is of particular importance in problems which involve hunting, instability, etc., and in which the torque (or displacement) angle must be predicted. This angle depends to a considerable degree upon the leakage reactance of the machine. It has been previously proposed by others to use two distinct values of leakage reactance, one when the leakage paths around a group or belt of armature slots are closed through the center of a pole face (maximum reactance), and the other when such slots are midway between the poles (minimum reactance). However, no account has been taken apparently of a gradual change in the reactance between the two extreme positions, nor have the results been properly correlated with the rest of the factors which enter in the performance of the machine.

In the present paper, the leakage inductance is assumed to consist of two parts, one of which is constant (the average inductance), and the other varying harmonically at a double frequency, reaches a maximum opposite the centers of the poles. A magnetic linkage equation is written, and its derivative with respect to the time angle is taken to obtain the induced voltage. The result shows that the foregoing assumption leads to two reactive drops, one, the usual average Ix drop and another a supplementary drop, leading Ix by an angle 2 ψ, where ψ is the internal phase angle at which the machine is operating. These quantities are introduced in the usual Blondel diagrams for the generator and the motor, and the relationships among the various quantities are established both graphically and analytically.

IN the performance characteristics of synchronous machines with salient poles, there are certain discrepancies between the computed and the measured electrical quantities, even when the usual Blondel diagram is used which is supposed to take into consideration the influence of salient poles on the armature reaction[2]. These discrepancies may be accounted

1. Professor of Electrical Engineering, Cornell University, and Engineering General Department, General Electric Co.

Presented at the Regional Meeting of District No. 1 of the A. I. E. E., Niagara Falls, N. Y., May 26-28, 1926.

2. For a theory of Blondel's diagram, see V. Karapetoff, *The Magnetic Circuit*, Arts. 48 and 49. The subject of direct and transverse armature reaction is also treated in detail in Chaps. 47 and 48 of the author's *Experimental Electrical Engineering*, Vol. II, 3rd ed., now going through the press. Extensive literature references will be found there.

for, at least in part, by taking into consideration the variations in the value of the permeance of the armature leakage flux during a cycle.

At zero power factor of the load, the armature leakage flux reaches a lower maximum value than with the same armature current at unity power factor, because in the latter case the armature slots, in which the current reaches its maximum, are almost opposite the centers of the poles, and the permeance of the leakage paths is greater. Hence, at high values of power factor, the machine should be expected to behave as if its leakage reactance were greater than that obtained from a short-circuit test. Often such is actually the case. Moreover, the torque (or displacement) angle[3] often comes out from test larger than from computation. This also indicates an actual increase in the equivalent reactive drop ix, as would be expected theoretically at higher values of power factor.

Several authors have pointed out the fact that the armature leakage reactance varies during the cycle, and some have used *two values of reactance*, one opposite the poles, the other midway between the poles[4]. However, to the writer's knowledge, *gradual changes* in the reactance have not as yet been considered quantitatively in their effect upon the Blondel diagram, and the latter is usually drawn with a constant ix drop. An attempt is made below to develop a method whereby such cyclic variations in the reactance can be taken into consideration in Blondel's theory of two armature reactions. Of course, a similar correction could be applied to the less accurate Potier diagram, but it would seem hardly logical to correct for the effect of salient poles upon the leakage reactance in a diagram in which the effect of salient poles on the armature reaction is disregarded altogether.

I. Average Reactance and Supplementary Reactance

In Fig. 1, the curve $A\ B\ C\ D\ E$ represents values of the armature leakage inductance plotted with reference to the axis of abscissas $X\ X$. The time angle is denoted by α, where

$$\alpha = 2\,\pi\,f\,t = \omega\,t \qquad (1)$$

t being time and f the frequency. When $\alpha = 0$, let the group of armature conductors under consideration be opposite the center of a pole. The tooth-tip leakage is then at a maximum, and hence the leakage inductance reaches its maximum value. When $\alpha = 90$ deg., the same group of conductors is midway between the poles and the leakage inductance is a minimum.

Thus, the leakage inductance varies at twice the frequency of the main induced voltage of the machine, and, as a first approximation, the inductance curve in this discussion will be assumed to be a sine wave of double frequency. Even when an actual test gives a curve departing from a sine wave, this experimental curve can be replaced by an equivalent sine wave, because higher harmonics in the inductance can produce only higher harmonics in the terminal voltage or in the current of the machine, and in this paper only the quantities of fundamental frequency are considered. The variable value of inductance, L_α, at an instant of time corresponding to the electrical angle α, shall therefore be expressed as

$$L_\alpha = L + \Delta\,L \cos 2\,\alpha \qquad (2)$$

Here L is the *average* value of the inductance over a cycle, and $\Delta\,L$ is the greatest departure from the average, that is, the amplitude of the sine wave with respect to the axis $X'\,X'$.

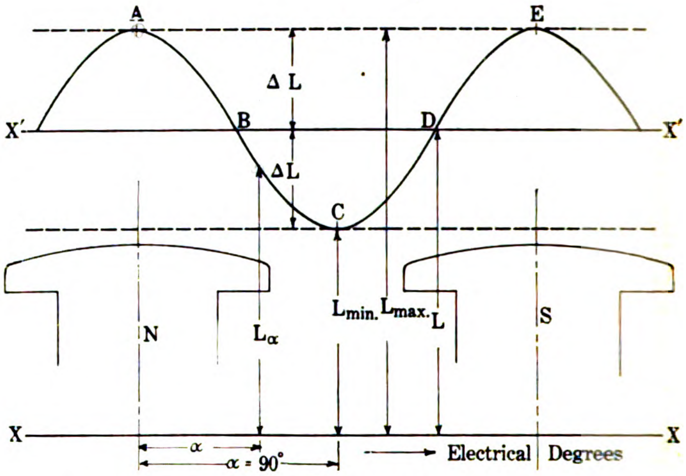

Fig. 1—Variable Armature Leakage Inductance L_α and Its Average Value L

Assuming the armature current to be sinusoidal, it can be written in the form

$$i_\alpha = I \cos(\alpha - \psi) \qquad (3)$$

where I is the amplitude of the current, and $\psi = Q\,O\,G$, Fig. 2, is the internal phase angle at which the machine is operating. The angle ψ characterizes the interval of time between the instant when a group of armature conductors is opposite the center of a pole and the instant when the current in the same group of conductors reaches a maximum[5]. For a generator, ψ is assumed to be positive when the current reaches a maximum *after* the corresponding group of conductors has passed by the center of a pole (although the current may be leading with respect to the terminal voltage). In a motor, ψ is greater than 90 deg., and may even be greater than 180 deg. when the motor is under-excited. Thus, in equation (3), the case of $\psi = 0$ corresponds to the generator working at such a power factor that the current I reaches its maximum when that group of

3. Mag. Cir., the angle $\beta + \phi_2$ in Fig. 40; this angle is denoted by θ in Fig. 2 of this paper.

4. See, for example, C. P. Steinmetz, *A-C. Phenomena*, Chapter on Armature Reactions in Alternators.

5. *The Magnetic Circuit*, pp. 154 and 155; the angle ψ is marked in the diagrams there.

conductors, through which I is flowing, is directly opposite the center of a pole. It can be shown that under these conditions the current is slightly leading with respect to the terminal voltage, but this fact is of no particular importance in this discussion.

Multiplying equations (**2**) and (**3**) term by term, in order to obtain the instantaneous magnetic linkages, gives,

$$i_\alpha L_\alpha = L\,I \operatorname{Cos}(\alpha - \psi) + \Delta L\,I \operatorname{Cos} 2\,\alpha \operatorname{Cos}(\alpha - \psi) \quad \textbf{(4)}$$

In the last term, the product of the cosines can be replaced by their sum and difference. Namely

$$\operatorname{Cos} 2\,\alpha \operatorname{Cos}(2\,\alpha - \psi) = 0.5 \operatorname{Cos}(\alpha + \psi) + 0.5 \operatorname{Cos}(3\,\alpha - \psi)$$

Leaving only the fundamental term containing α, and

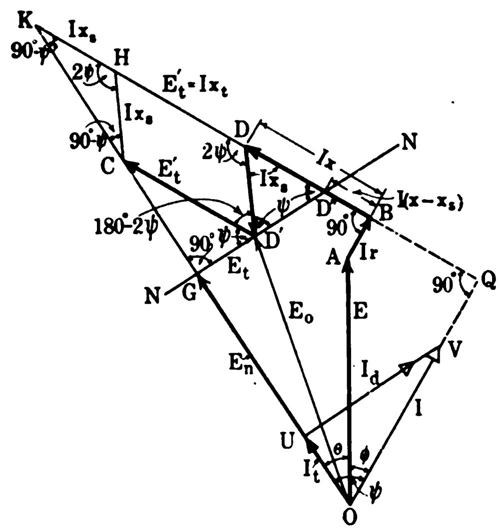

FIG. 2—A MODIFIED BLONDEL DIAGRAM OF A SYNCHRONOUS GENERATOR WITH THE AVERAGE REACTIVE DROP, Ix, AND SUPPLEMENTARY REACTIVE DROP, Ix_s

disregarding the term with $3\,\alpha$ (the third harmonic), *approximately*,

$$i_\alpha L_\alpha = L\,I \operatorname{Cos}(\alpha - \psi) + 0.5\,\Delta L\,I \operatorname{Cos}(\alpha + \psi) \quad \textbf{(5)}$$

The voltage drop due to these linkages is

$$e_x = d\,(i_\alpha L_\alpha)/d\,t = \omega\,d\,(i_\alpha L_\alpha)/d\,\alpha \quad \textbf{(6)}$$

Hence, taking a derivative of equation (**5**),

$$e_x = -\,\omega\,L\,I \operatorname{Sin}(\alpha - \psi) - 0.5\,\omega\,\Delta L\,I \operatorname{Sin}(\alpha + \psi) \quad \textbf{(7)}$$

The term $-\,\omega\,L\,I \operatorname{Sin}(\alpha - \psi)$ represents a sine voltage which leads the current wave by 90 deg. and corresponds to the average constant reactance

$$x = \omega\,L \quad \textbf{(8)}$$

such as ordinarily used in the theory of synchronous machines. The last term in equation (**7**) corresponds to a *supplementary reactance*

$$x_s = 0.5\,\omega\,\Delta L \quad \textbf{(9)}$$

The corresponding voltage drop, $x_s\,I \operatorname{Sin}(\alpha + \psi)$, *leads* the main reactance drop $I\,x$ by the angle $2\,\psi$, because

$$(\alpha + \psi) = (\alpha - \psi) + 2\,\psi \quad \textbf{(10)}$$

Thus, the following expression is reached for the vector of total reactive voltage drop in the armature:

$$\text{Reactive drop} = I\,x\,\underline{/90°} + I\,x_s\,\underline{/90° + 2\,\psi} \quad \textbf{(11)}$$

The quantities x and x_s are expressed by equations (**8**) and (**9**); the values of L and ΔL are shown in Fig. 1. The angle notation in equation (**11**) means that $I\,x$ leads the vector I by 90 deg. and $I\,x_s$ leads I by 90 deg. $+ 2\,\psi$. In other words, $I\,x_s$ leads $I\,x$ by $2\,\psi$.

II. A MODIFIED BLONDEL DIAGRAM

An application of these results to the Blondel diagram is shown in Figs. 2 and 3 which are generalized Figs. 40 and 41 in the "Magnetic Circuit." Fig. 2 represents a generator at a lagging current and Fig. 3 a motor at a leading current[6]. The current I is shown in both cases from the point of view of the machine itself (and not of the line) so that the phase angle ϕ, when the machine is operating as a motor, is greater than 90 deg. This method of representation is of advantage in that the same diagram and the same set of formulas cover operation both as a generator and as a motor.

Beginning with the line voltage E, Fig. 2, the ohmic drop $A\,B = I\,r$ is added in phase with the current, and the average reactive drop $B\,D = I\,x$ in leading quadrature with it. The supplementary reactive drop, $I\,x_s = D\,D'$, is added at an angle $2\,\psi$ to $B\,D$, in the positive (counter-clockwise) direction. In the case of the motor, ψ is greater than 90 deg., and $2\,\psi$ is greater than 180 deg. $E_0 = O\,D'$ is the total induced electromotive force. The direction $O\,C$ is that of the induced electromotive force at no load, or the center line of the pole. Hence, by constructing a right-angle triangle $D'\,G\,O$, with $O\,D'$ as hypotenuse, the net voltage $O\,G = E_n$ induced by the real poles is obtained, and the voltage $G\,D' = E_t$ induced by the fictitious (transverse) poles.

From equations (**83**) to (**85**) on p. 156 of the "*Magnetic Circuit,*" it will be seen that instead of drawing E_t normal to $O\,C$, a vector $D'\,C = E_t'$ can be drawn parallel to $I\,x$. This procedure is necessary when the angle ψ is not known, and in fact can be used to determine this angle, namely, by completing the parallelogram $D\,D'\,C\,H$ and extending $D\,H$ to its intersection with $O\,C$ at K[7]. In the triangle $K\,H\,C$ the angle at H is equal to $2\,\psi$ by construction; the angle at K is equal to 90 deg. $-\,\psi$, because $O\,Q\,K$ is a right triangle, and the angle at 0 is equal to ψ. Thus, in the triangle $K\,H\,C$ the remaining angle, at C, is also equal to 90 deg. $-\,\psi$.

6. The current and voltage notation has been changed from i and e to I and E; the induced voltage is denoted by E_0 in place of E. I has been defined above as the amplitude of the current. There is no objection, however, to considering I and E in the diagram as vectors of the effective values.

7. The point K is of considerable importance in diagrams of synchronous machines, and Blondel uses the term Joubertian e. m. f. for the value of $O\,K$. It is convenient to call K the Joubertian point.

The triangle is isosceles and consequently $H K = i x_s$. This gives the following construction for the angles ψ and θ:

Lay off $O A$ and $A B$, and draw the direction $B K$, normal to the current. Lay off $B K = I x + E_t' + I x_s$, and connect point K to 0. This will give both the internal phase angle ψ and the displacement of torque angle θ. The latter is the electrical angle by which the pole structure of the loaded machine is advanced (or retarded) with respect to an identical unloaded machine connected to the same bus bars.

If it is required to compute the required excitation, complete the diagram by laying off $B D'' = I$

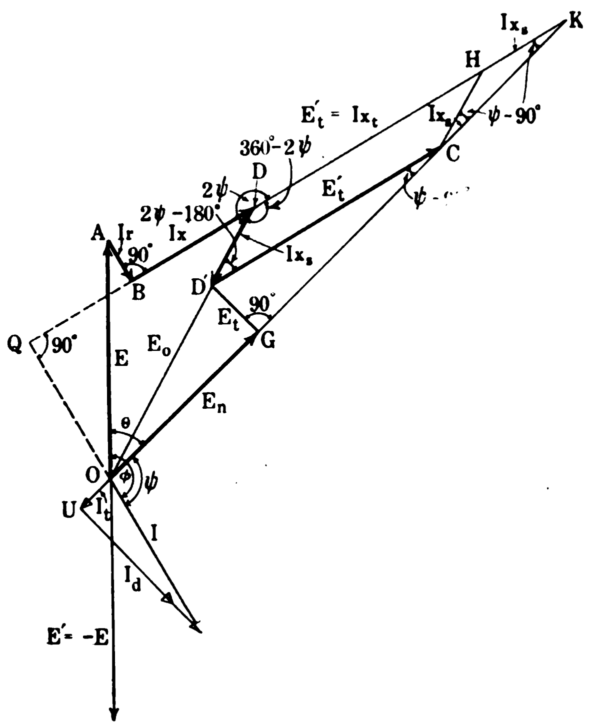

Fig. 3—A Modified Blondel Diagram, Similar to Fig. 2, for Synchronous Motor

($x - x_s$), and through D'' draw the straight line $N N$ normal to $O K$. This will determine the net induced electromotive force $O G = E_n$; from the no-load saturation curve, the corresponding net excitation, M_n, can be found. To this excitation, the direct armature reaction, M_d, is added [or subtracted, if sin ψ is negative, *ibid.*, equation (**79**)]. This will give the required field excitation, M_f, at that particular load.

Most of the construction lines and angles indicated in Fig. 2 are also shown in Fig. 3, and the description given above, with slight modifications, may also be followed in Fig. 3.

III. Analytical Solution

The heavily drawn polygon in Fig. 2 can be represented in the cissoidal complex form by the equation

$$E \operatorname{Cis} \phi + I r \operatorname{Cis} 0 + I x \operatorname{Cis} 90 \text{ deg.} + I x_s \operatorname{Cis} (90 \text{ deg.} + 2\psi) + I x_t \operatorname{Cis} 90 \text{ deg.} = (E_n + I x_t \operatorname{Sin} \psi) \operatorname{Cis} \psi \quad (\mathbf{12})$$

where

$$\operatorname{Cis} \phi = \operatorname{Cos} \phi + j \operatorname{Sin} \phi = \epsilon^{j\phi} \quad (\mathbf{12a})$$

and also

$$I x_t = E_t' = I k_t k_b m n v \quad (\mathbf{13})$$

[*Magnetic Circuit*, p. 156, equation (**84**)], so that the *transverse reactance*, corresponding to the transverse armature reaction, is

$$x_t = k_t k_b m n v \quad (\mathbf{13a})$$

Equation (**12**) expresses the fact that the geometric sum of $O A, A B, B D, D D'$ and $D' C$ is equal to $O G + G C$. To solve this equation for ψ, multiply both sides by Cis (90 deg. $- \psi$)[8]. The real part of the resultant expression is

$$E \operatorname{Sin} (\psi - \phi) + I r \operatorname{Sin} \psi - I x \operatorname{Cos} \psi - I x_s \operatorname{Cos} \psi - I x_t \operatorname{Cos} \psi = 0 \quad (\mathbf{14})$$

Dividing throughout by Cos ψ and solving for tan ψ,

$$\tan \psi = (E \operatorname{Sin} \phi + x_0 I) / (E \operatorname{Cos} \phi + I r) \quad (\mathbf{15})$$

where x_0 is the total equivalent reactance:

$$x_0 = x + x_t + x_s \quad (\mathbf{15a})$$

A reference to Fig. 2 will show that equation (**15**) could be written directly from the triangle $O Q K$, since in this triangle

$$\tan \psi = Q K / O Q \quad (\mathbf{16})$$

However, a derivation from equation (**12**) has been deemed to be of sufficient interest to be included in this paper for the sake of illustrating the general method of solution of such problems. This method is entirely automatic, while the particular geometric relations in a given problem may or may not be evident. The displacement angle θ is determined from the relationship

$$\theta = \psi - \phi \quad (\mathbf{16a})$$

for a motor θ is negative.

Equating separately the real and the imaginary parts on the two sides of equation (**12**), and solving each for the term with E_n, we obtain:

$$E_n \operatorname{Cos} \psi = E \operatorname{Cos} \phi + I r - I (x_s + 0.5 x_t) \operatorname{Sin} 2\psi \quad (\mathbf{17})$$

$$E_n \operatorname{Sin} \psi = E \operatorname{Sin} \phi + I (x + 0.5 x_t) + I (x_s + 0.5 x_t) \operatorname{Cos} 2\psi \quad (\mathbf{18})$$

Knowing the angle ψ from equation (**15**), E_n can be computed from either equation (**17**) or (**18**). When ψ is near zero, it is preferable to use equation (**17**); when ψ is nearly 90 deg., equation (**18**) will give more accurate results.

A graphical interpretation of equations (**17**) and (**18**) is shown in Fig. 4. This diagram is identical with Fig. 2, except that a line, $G W$, is drawn perpendicular to $O Q$. The lengths $D' R$ and $R G$ are each equal to $0.5 E_t'$. Equation (**17**) then simply means that

$$O W = O Q - W Q \quad (\mathbf{19})$$

while equation (**18**) states that

$$W G = R G + W R \quad (\mathbf{20})$$

8. Two Cis operators are multiplied by simply adding the angles; that is, Cis a. Cis b = Cis ($a + b$). This follows directly from the exponential expression in equation (**12a**); see also V. Karapetoff, *The Electric Circuit*, p. 93, equation (**154**).

Whether or not this graphical relationship will prove to be of further practical interest, remains to be seen. It has been deemed advisable to note it here, as a check on the formulas.

The theory deduced above has been checked on a machine with an exceptionally high leakage reactance. The assumption of a constant leakage reactance, deduced from the short-circuit test and from the design data of the machine, led to a wide discrepancy between the observed and computed performance characteristics.

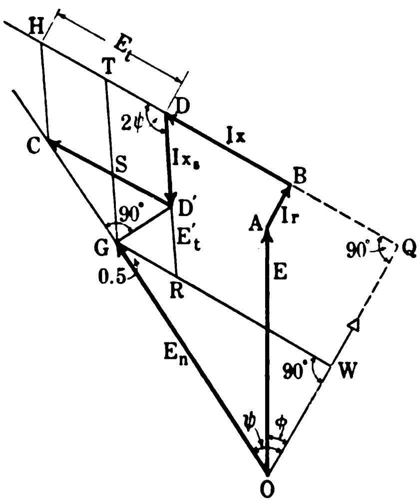

FIG. 4—A GRAPHICAL INTERPRETATION OF EQUATIONS (17) AND (18)

On the other hand, by assuming reasonable values of the average and supplementary leakage reactances, the current and voltage relations, as well as the torque angle θ, were found to agree quite closely with the test data[9].

In conclusion, the author wishes to express his appreciation to Mr. R. E. Doherty, Consulting Engineer of the General Electric Company, for suggesting this investigation and for encouragement while it was in progress.

CORRESPONDENCE

DISCUSSION ON ALTERNATING-CURRENT ANALYSIS ALTERNATING-CURRENT ANALYSIS (MERSHON)

To the Editor:

The statement which appeared in the May 1926 JOURNAL concerning the use in several text-books of the method presented by Mr. Mershon was hastily written on the basis of impression rather than fact. Since then I have attempted, but failed, to find the method in any of the usual texts. I take this opportunity to correct my error and apologize to Mr. Mershon.

PREDETERMINATION OF SELF COOLED, OIL IMMERSED TRANSFORMER TEMPERATURES BEFORE CONDITIONS ARE CONSTANT

The predetermination of temperature rise-time-curves for transformers is of the utmost importance for the calculation of permissible durations of overloading.

In the paper of *Mr. Cooney* in the JOURNAL of December 1925 methods are given to obtain a more accurate calculation of these curves. The special methods pointed out by the author are, first, the separation of the temperature rise of the winding above the ambiant air in the temperature rise of the winding above the oil and the temperature rise of the oil above the ambient air and, second, in taking into account the fact that the heat dissipation increases more rapidly than according to the first power of the temperature difference.

My note refers to this last point. The fact that the coefficient of cooling of a transformer increases with increase of temperature difference is expressed by the author in the formula:

$$\theta = k\,P^{0.8} \qquad \textbf{(a)}$$

This formula is used to calculate the final temperature rise at different losses (loads).

For the tracing of the temperature rise-time-curve the general known ϵ relation is used.

It seems to me that a temperature rise-time-curve still more in accordance with test curves may be obtained by taking into account the formula (**a**) also for the calculation of this curve. We shall give below a method by which this can be done.

The formula (**a**)

$$\theta = k\,P^{0.8}$$

can be written

$$\theta = \left(\frac{k^{1.25}}{\theta^{0.25}} \right) P \qquad \textbf{(b)}$$

By this formula it can be seen that the coefficient between brackets diminishes by increased values of θ. According to formula (*b*) the coefficient of dissipation will vary with the value $\theta^{0.25}$.

Thus, the value for the loss dissipated can be written:

$$K_f \frac{\theta^{0.25}}{\theta_f^{0.25}}\,\theta \qquad \textbf{(c)}$$

In this formula $K_f \,.\, \theta_f$ is the loss dissipated at the temperature difference θ_f, for the generated loss can be written

$$W = W_0\,(1 + \beta\,\theta)$$

W_0 is the loss for $\theta = 0$.

β is indifferent from α and takes into account the fact that the loss consists of iron and copper losses. Taking $\alpha = 0.004$ and the ratio between the iron and copper losses to be 1 : 3 the coefficient β will be 0.003.

The formula (3) of the paper can be written now as follows:

$$W_0 (1 + \beta\,\theta) = C \frac{d\,\theta}{d\,t} + K_f \frac{\theta^{0.25}}{\theta_f{}^{0.25}} \,.\, \theta$$

Taking the time constant:

$$T_\epsilon = \frac{C\,\theta_f}{W_0}$$

the following equation is obtained

$$\frac{d\,t}{d\,\theta} = T_\epsilon \frac{\theta_f{}^{0.25}}{\theta_f{}^{1.25} - \theta^{1.25} + \beta\,\theta\,\theta_f\,(\theta_f{}^{0.25} - \theta^{0.25})} \quad \textbf{(d)}$$

The integration of this formula is difficult. The curve can be easily computed, however, by taking small

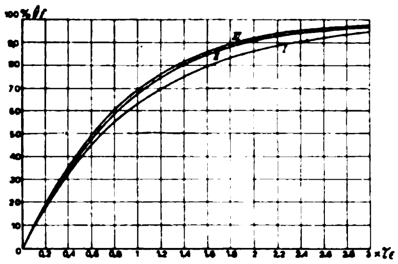

Fig. 1

intervals $\Delta\,\theta$ and calculating for the mean value of ||| θ of this interval the value of $\frac{\Delta\,t}{\Delta\,\theta}$. The time intervals can be obtained then by multiplying $\frac{\Delta\,t}{\Delta\,\theta}$ by $\Delta\ \theta$.

In this way the curve III of Fig. 1 is obtained. For θ_f is taken 100, for $T_\epsilon = 1$ and for $\beta = 0.003$.

Curve II is obtained by taking $\beta = 0.$, *i.e.*, by assuming the losses to be constant at all temperatures.

Curve I shows the well known ϵ curve.

In the middle part of the curves, III and II show a stronger curvature (radius of curvature smaller) than the curve I.

The fact that test values show generally the same deviation from the simple ϵ curve proves that the curve III is the more correct one.

Appendix

Derivation of formula (**d**).

$$W_0 (1 + \beta\,\theta) = C \frac{d\,\theta}{d\,t} + K_f \frac{\theta^{0.25}}{\theta_f{}^{0.25}}\,\theta$$

For $\theta = \theta_f$

$$W_0 (1 + \beta\,\theta_f) = K_f\,\theta_f \text{ or } K_f = \frac{W_0\,(1 + \beta\,\theta_f)}{\theta_f}$$

Thus

$W_0(1 + \beta\,\theta) = C\ \ d\,\theta - \ + W_0\,1 + \beta\,\theta_f$

$$W_0(1 + \beta\,\theta) = C \frac{d\,\theta}{d\,t} + W_0 \frac{1 + \beta\,\theta_f}{\theta_f} \frac{\theta^{0.25}}{\theta_f{}^{0.25}}\,\theta$$

$$W_0 \left[1 + \beta\,\theta - \frac{\theta^{1.25}}{\theta_f{}^{1.25}} - \beta \frac{\theta^{1.25}}{\theta_f{}^{0.25}} \right] = C \frac{d\,\theta}{d\,t}$$

$$W_0 \left[1 - \frac{\theta^{1.25}}{\theta_f{}^{1.25}} + \beta\,\theta \left(1 - \frac{\theta^{0.25}}{\theta_f{}^{0.25}} \right) \right] = C \frac{d\,\theta}{d\,t}$$

$$\frac{d\,t}{d\,\theta} = \frac{C\,.\,\theta_f}{W_0} \frac{\theta^{0.25}}{\theta_f{}^{1.25} - \theta^{1.25} + \beta\,\theta\,\theta_f\,(\theta_f{}^{0.25} - \theta^{0.25})}$$

$$= T_\epsilon \frac{\theta^{0.25}}{\theta_f{}^{1.25} - \theta^{1.25} + \beta\,\theta\,\theta_f\,(\theta_f{}^{0.25} - \theta^{0.25})}$$

POSSIBLE DISCONTINUANCE OF RADIO STANDARD FREQUENCY TRANSMISSIONS

BY BUREAU OF STANDARDS

Since March, 1923, the Bureau of Standards has been transmitting, twice a month, radio signals of definitely announced frequencies for use by the public in standardizing frequency meters (wave meters) and transmitting and receiving apparatus. The signals are transmitted from the Bureau station, W W V, Washington, D. C., and from station 6XBM, Stanford University, California.

Since other means of freely disseminating the Bureau's standards of frequency are becoming increasingly available, the Bureau has considered the termination of the standard-frequency transmissions. The other means referred to are the lists of standard-frequency stations regularly given in the Radio Service Bulletin, published by the Bureau of Navigation, the use of piezo oscillators, and the wide availability of reliable standards and test service from a number of laboratories that do commercial testing of frequency meters. None of these means were available when the standard-frequency transmissions were inaugurated.

The standard-frequency transmission schedules already announced to extend through June and perhaps to October will be carried out as published, but the Bureau of Standards is announcing the possible termination of the service after that date in order that persons who depend upon the service in any special way may inform the Bureau of any objection to its termination, especially persons in the western part of the United States, who have been utilizing the signals from Stanford University, until the listing of standard-frequency stations on the west coast should have been begun. Letters on this subject may be addressed to Bureau of Standards, Department of Commerce, Washington, D. C.

Discussion at Midwinter Convention

SUPERVISORY SYSTEMS FOR ELECTRIC POWER APPARATUS[1]

(LICHTENBERG)

NEW YORK, N. Y., FEBRUARY, 9, 1926

C. E. Stewart: I should like, briefly, to call attention to one or two things of interest. In the first place, supervisory systems have passed the experimental stage. We have had actual service out of the systems so that we know that they are successful in the field for which they are intended. By the end of this year, systems put out by the General Electric Company alone will have supervision over some 2500 oil circuit breakers or their equivalent. We shall have in service a distributor type whereby a dispatcher at a central point will have supervision over breakers located in twenty-two out-lying stations.

Another very interesting application of supervisory systems will be made on an electrified railroad division sixty miles long between Chicago and South Bend, whereby a load dispatcher in Chicago will control eight automatic stations by means of a carrier selector system operating over one wire and ground-rail return. He will be able to start and stop any station, open and close the feeders going out from the station, and also control incoming lines in some cases.

R. J. Wensley: Mr. Lichtenberg says that telephone relays are not suited for supervisory control service. With this statement I do not agree. I would like to call attention to several installations in the New York area which depend entirely on telephone relays for reliability in operation. The equipments in actual operation seem to be the best refutation of Mr. Lichtenberg's condemnation of telephone relays.

The Long Island Railroad has one of the simple audible types in service controlling a remote 600-volt switch house. It is controlled by a dial and a howler gives an audible answer. It works over two wires and is the least expensive type of control.

This same company has a more elaborate equipment of the code-visual type in service at Amityville controlling one 2000-kw. converter in 600-volt railway service.

The New York Edison Company has a remote selective metering equipment in service at their Forty-First Street substation which transmits readings of volts and amperes over standard telephone cable.

The New York and Queens Electric Light and Power Company has a very comprehensive set of relay-visual equipment in the Woodhaven substation. With it they can control oil breakers, adjust induction regulators, bring in spare regulator and transformer when needed, and make necessary simultaneous readings of a-c. volts and amperes. These functions are all accomplished over telephone cable with a relatively few wires.

The most extensive equipment in this area is that on Staten Island. The equipment is used jointly by the Staten Island Rapid Transit Company and the Staten Island Edison Company. It is of the all-relay visual type. Five railway substations and one power-distribution substation are controlled from one dispatching point. Two separate-control desks use the same relay equipment to handle the business of the two operating companies.

H. C. Don Carlos (communicated after adjournment): In the operation of two generating stations under supervisory control, the Hydro-Electric Power Commission has encountered, among others, some very interesting protective problems. Although the final step in remedying certain troubles has not yet been taken, the following comments on them may be of interest to the profession.

The stations in question are near Campbellford, Ontario, on the Trent river, a navigable stream on which they form three successive developments with navigable reaches intervening. Ranney Falls or No. 10, the upstream station, is the point of control for Nos. 9 and 8, the total distance between plants 10 and 8 being three and a half miles. In No. 9 there are three vertical generators, each of 1400-kv-a. capacity, and in No. 8, three vertical generators of 2000-kv-a. capacity each. In common with a number of other stations, they supply power to a 44,000-volt, 60-cycle network, complicated by a large number of loops.

Since the navigation regulations limit the permissible variation of the level of the small reaches between the plants to about two inches, there is practically no storage available, and consequently very exact information is required at the control point on reach levels, plant output, gate openings (in tenths) of all turbines, as well as switch positions and various other control data. For each of the stations, something over fifty supervisory operations are performed in addition to the transmission of three graphic records. A twenty-pair standard, lead-covered telephone cable, located on a separate pole line, 25 ft. from a 44,000-volt power line, connects No. 10 to No. 9, and a ten-pair cable continues on to No. 8.

The No. 8 generating station went into operation under manual control, using automatic equipment, September 11, 1924, and under remote supervisory control, January 13, 1925. A great deal of trouble was at first experienced, which required patient study and careful analysis to eliminate. With few exceptions the equipment itself is now performing very well and gives promise of ultimate success if the disturbing effects of power short-circuits and lightning trouble can be overcome.

Soon after the supervisory cable went into operation, trouble began to develop in it, affecting one or more conductors each time, and occasionally actual burn-outs occurred. The more serious faults were traced down and eliminated, but after a time all spare conductors had been used, and finally we were left without sufficient clear wires to operate.

Induced disturbances due, to the proximity of the 44,000-volt power line, were at first suspected as the cause of our trouble, but theoretical considerations showed that since the sheath was grounded at all three stations, inductive effects could not be responsible. The use of insulating joints in the cable sheath, splitting it into numerous sections grounded at each end, was one of the proposals most frequently advanced by those who were not thoroughly familiar with the problem.

For various reasons, the sheath must be grounded to the apparatus ground of all three stations. The main trouble is caused by differences in potential between the so-called grounds (*i. e.*, the prevailing potential of the ground leads and steel work within the building) of any two of the three stations due to our inability to obtain a sufficiently high-capacity and low-resistance "ground."

This potential difference is uniformly distributed over the cable sheath (which carried a portion of the fault current) between the two stations. The conductors, however, are normally at uniform potential from end to end, and their insulation is quite unable to withstand the stresses due to the potential drop along the sheath, which may be upwards of 8000 volts.

This surprising figure has a simple explanation. The ground resistance at each of the three stations is in the order of two ohms each, and the cable-sheath resistance is nearly 10 ohms. The possible fault current is in the order of 3000 amperes. Duly considering the return distribution of fault current, calculations and tests indicate a probable maximum potential difference of 8000 volts.

It should be remarked that the frequency of our troubles is attributed to the use at No. 10 of a common ground for the power neutral and the station apparatus (the neutrals at Nos. 9 and 8 are not grounded), so that a 44,000-volt fault anywhere on the system causes a difference in potential between the station

1. A. I. E. E. JOURNAL, February, 1926, p. 116.

ground at No. 10 and those at Nos. 9 and 8. This, of course, occurs despite the fact that the power neutral is grounded at two other locations. To remedy this condition, a separate ground for the power neutral has recently been installed at a considerable distance from the station ground, as a result of which the station ground, in large measure, is freed from variations in potential due to fault currents in the neutral. When again in operation, the supervisory cable will thus be undisturbed by faults other than those at one of the three stations in question.

Among the numerous remedies considered may be mentioned:

a. The adoption of a-c. supervisory operation with transformers at each end of the cable completely isolating the conductors from the station ground, or from any apparatus connected thereto.

b. The use of a stabilizing ground conductor of sufficient admittance to limit the possible voltage difference between the three station grounds to an amount which would not prove injurious to the cable.

c. The use of transformers, the primary of which would be connected between the cable sheath and the station ground, and the secondary of which would consist of all the other conductors of the cable wound in close coupling and of such ratio (approximately 1:1) as to cause the conductors to follow approximately the same potential gradient as the sheath.

In addition to the foregoing, the idea of installing a highly insulated cable has been advanced, but this would not help matters since the supervisory equipment, which, in itself, will not withstand high potentials, would be still subjected to the severe stresses and cannot, according to the manufacturer, be protected against trouble of the nature described without blowing fuses which render it inoperative until an attendant makes replacements.

Of the three schemes mentioned, (a), which was developed independently by the Commission and the manufacturer, appears to have merit, but it is expensive and involves the use of additional equipment in the automatic train, and the consequent additional care and maintenance and risk of failure is objectionable. Plan (b) is also expensive, and lacking in some of the merits of (a), although free from its shortcomings. On the whole, (c), proposed by R. W. Osborne, telephone engineer of the Commission, seems to offer the greatest return for the investment, and the greatest promise of satisfactory ultimate operation. Preliminary tests of its behavior under transient disturbances are now pending.

It is interesting to note the manufacturer's contention that conditions exist in this installation which have not been encountered before, yet we are all agreed that the trouble is due to differences in potential between the ground conductors of any two of the stations. So far as I am aware, our ground resistances are not high for isolated plants and are not capable of any considerable improvement consistent with a reasonable outlay which can be relied upon the year round. In fact, the expensive proposition of ground stabilization by means of an interconnecting cable (scheme b) would be cheaper, and, if feasible, far more positive than an attempt to overcome the trouble by further improving the station grounds.

The question of how usual or unusual the conditions are can be decided by any interested engineer who has a general knowledge of the dependable minimum resistances of ground connections, and if he has any particular case in mind and knows the ohmic resistance of the grounds and the maximum fault current, he can calculate the probable resulting potentials in a supervisory installation from causes such as I have described.

In his remarks under the heading "Protection," Mr. Lichtenberg has shown a very open mind and has stated his interest in the experience of operating companies. Some of his views seem to be at variance with the conclusions drawn in the foregoing, and in support of these conclusions I can only add that practical operating experience as well as theory seem to be in agreement—a circumstance which always carries weight.

F. R. McBerty (communicated after adjournment): Mr. Lichtenberg's contribution on the subject of the maintenance of supervisory systems composed of telephone relays (which is in substance a repetition of his remarks before the meeting reported in the JOURNAL of August, 1925, page 879) demands some qualification in the records of the Institute. Mr. Lichtenberg's experience with such relays must have been both limited and unfortunate. Having participated in the design of the telephone relays most extensively used throughout the world and being now the manufacturer of an "all-relay" supervisory system for power equipments, I can perhaps offer definite and accurate information on these matters.

Mr. Lichtenberg is in error in his statement as to the fundamental ideas and assumptions present in the minds of the designers of telephone relays. The designers as a matter of fact did not work under the idea that the relays would be or could be inspected frequently or that some person would be present at one end or the other of a line equipped with them to note their failures and ensure their operation. On the contrary they had in mind that such relays would be used in great numbers, would be operated by persons intent on telephonic communication, would be operated in constantly shifting combinations which would make discovery of individual failure difficult, and would largely determine the reliability of telephone service. The designing and making of relays which should be both sufficiently cheap in cost and sufficiently reliable in service was so well done that there are now scores of millions of them in service throughout the world, of which a large part have been in operation for a quarter century performing thousands of millions of operations per day with a percentage of failure so slight that of all common causes of defect in the operation of telephone systems, the failures of telephone relays form a negligible factor.

Among manual-exchange systems composed of such relays there is no daily inspection, and in most cases not even an annual nor a decennial inspection or test; in machine-switching systems the faults due to relays are a trifling factor in comparison with the faults caused by step-by-step or power-driven moving switch mechanism.

The supervisory system illustrated in Fig. 12 of Mr. Lichtenberg's paper is composed of telephone relays of a type used for performing selection in the automanual city telephone exchange systems and in automatic or dial-controlled private exchanges. As an example, a single unit has performed on test more than fifty million circuit closings without failure or significant change in contact resistance. There are large city exchanges in operation in which the initial selections for all originating telephone calls are made by such relays comprising a total of about sixty thousand relays, some of which have been in continual operation for fifteen years, which are never inspected or tested and which collectively show failures or defects in operation numbering no more than two hundred cases per year in the performance of about five hundred million selective operations. In a particular large exchange the ratio of failures to selections is about one in five million. These relays have never been given routine tests and have had only occasional and in some cases, no inspection since installation.

Reference was made by Mr. Lichtenberg, in his paper dealing with the same subject matter reported in the JOURNAL of last August, to the wide range of temperature under which supervisory systems must operate. Relay selection gear fulfills these requirements far better than any other form of selecting mechanism in existence. As an example, there is an unattended remote-controlled all-relay telephone exchange in Ohio, which gives continual local and long-distance service to about 140 subscribers, situated at a distance of sixteen miles from a city and operated over a pair of control wires from the city, housed in a small building without any means of controlling temperature or hu-

midity. The relay selection equipment has developed only one fault in fourteen months, has had only casual inspection without any adjustment or repair whatever in seven months, and has been without even a visit from an inspector for ten weeks during the winter. During this time there have been no cases of interruption of service or of failures in selection traceable to the relay switching equipment.

The conspicuous merits of the relay selection systems composed of telephone relays, as compared with step-by-step, ratchet-driven and with rotary power-driven selective gear, are as follows:

The moving parts of the relays are pivoted armatures and long flexing flat springs only, with small and fixed ranges of movement with ample factor of safety in power working against relatively unchanging frictional resistance. The contacts themselves, when multiplied, are for all practical purposes free from failure. When properly constructed the relays never afterwards require adjustment or cleaning. The complications of the selective gear lie in the circuits, which being in the form of soldered and cabled wire net works are unchanging and permanent.

Such relays could readily be made much heavier and even more ornamental, but so far as I am aware there are no reasons other than personal taste to warrant the added expense. After all the function of a relay is to move a bit of bronze or platinum against another bit, and telephone relays do that very well.

On the contrary step-by-step or constantly moving selective mechanism is in all cases dependent upon the operation of relays, subject to whatever failures may characterize relays, with the additional handicap of being itself composed of numerous small moving parts—ratchets, pawls, retractile springs and brushes—among which accurate, minute, mechanical adjustments must be closely maintained under driving forces varying widely and against frictional resistance and inertia also varying widely. Its complications lie largely in nice relations of moving parts and forces. In order to be operative such mechanism universally requires rather closely regulated voltage, must be adjusted, lubricated, and kept free from dust and oxidized metal—conditions which change with use, atmospheric conditions and time.

Chester Lichtenberg: Supervisory systems, as mentioned in the paper, are new. Only a few of them have been in service sufficiently long to obtain experience with them. The discussion presented by Mr. Don Carlos is, therefore, exceedingly valuable since it presents in most thorough fashion an operating problem together with three suggested solutions of it.

The discussions of Messrs. Stewart, Wensley and McBerty present data which supplement that given in the paper and express opinions relative to operation. These opinions are indeed very valuable, since designers of supervisory systems will no doubt examine and take from them such suggestions as will prove of material benefit to the art.

A discussion of supervisory systems cannot be concluded without again making clear the fact that these systems are quite different from remote-control systems and, therefore, their application must be carefully made if they are to be successful.

THE CROSS-FIELD THEORY OF ALTERNATING-CURRENT MACHINES[1]

(West)

New York, N. Y., February 11, 1926

P. L. Alger: Mr. West has presented in his paper a business-like and accurate way of obtaining the characteristics of an a-c. motor. The method is particularly adapted, and, in fact, was especially intended, for use by engineers having to do with large numbers of motors. Probably we all agree that the circle diagram, or some similar graphical method, is most suitable for college instruction, and for use by persons only dealing with motors occasionally. When large quantities of motors are to be designed, however, it is necessary to take into account many of the minor features of the theory, and, at the same time, to make the method extremely systematic. Thus, I am heartily in sympathy with the point of view which Mr. West expounds so thoroughly.

While the title of the paper emphasizes the cross-field theory, the same method could be used equally well with the rotating-field theory, for most machines. It is my opinion that both the rotating-field and the cross-field theories have advantages in particular cases, and that a complete understanding of design can be obtained only by a mastery of both theories. So far as I know, there is only one respect in which the two theories give different results.

This one exception occurs when the secondary winding of a single-phase machine has sufficient skin effect to make its effective resistance and reactance at line frequency appreciably different from their values with direct current. Since the actual current in any one secondary conductor consists of components of two different frequencies, the two components encounter different impedances, and so the effective voltage across the conductor is not equal to the product of the total current by any definite value of impedance. The cross-field theory treats the entire current in one axis as being of line frequency, and so does not take into account the variation of impedance with frequency. On this account, the rotating-field theory gives more accurate results for machines of this type.

I believe that the obvious objection to Mr. West's method, that it is very complicated, can be largely overcome by a study of the formulas, and their rearrangement into a form consisting of a principal term and various corrective terms. For example, if the magnetizing reactance is large by comparison with the leakage reactance, many of the formulas can be simplified by expressing them in power series in terms of $\frac{x}{X_m}$, and then neglecting higher powers than the first of this ratio. In some cases, the most complicated formulas can be put into a simple and usable form by assuming average values for certain of the less important constants, and preparing charts showing the effects of variations in the major constants. Then, correction formulas can be made up, showing the effects upon the result of changes in the minor variables made independently, and these auxiliary formulas can be used whenever especial accuracy is desired.

I believe that the ultimate design method is one which takes into account all of the variables, but only carries the result to the desired accuracy, and no further.

K. L. Hansen: In his analysis of the single-phase, induction motor, Mr. West has followed the usual and much discussed method of the cross-field theory. He has, apparently, introduced a slight modification by adding the secondary leakage flux to the mutual flux in the expressions for some of the induced voltages. The introduction of this refinement is, however, incidental and is obviously not the main object of the paper.

In the opening paragraph the author states that some phenomena are more easily understood by a study following the revolving-field theory, and other phenomena are made more clear by use of the cross-field theory. This statement, in connection with the title of the paper, would naturally lead one to believe that some distinct advantage of the cross-field theory over the revolving-field theory would be pointed out, at least in the specific instances which the author has chosen for illustration. The paper does not fulfill this expectation.

According to the author, the choice of methods should depend on what is most desired, *e. g.*, speed, accuracy, or aid to visualization. From the standpoint of speed and accuracy the cross-field theory obviously offers no advantage over the rotating-field theory. From the standpoint of visualization or physical conception the cross-field theory appears to be rather inferior to the rotating-field theory. Indeed, at the very outset an artifice

1. A. I. E. E. Journal, February, 1926, p. 160.

is resorted to of considering the squirrel cage as the equivalent to a commutated winding with brushes bearing on the commutator short-circuited on themselves in the transformer and field axes.

There can be no objection to replacing the actual circuits we are dealing with by artificial equivalent ones when something is gained from the standpoint of clearness or shortening of the analytical work; but in this instance nothing is apparently gained thereby. In the revolving-field theory the squirrel cage is considered to be exactly what it is—a system of polyphase circuits. It seems that the currents flowing in the artificial secondary circuits employed by the author are of constant frequency and that therefore the secondary reactance x_2 is a constant quantity independent of the slip. Have the calculations in the paper been made on that assumption, and if so, do they lead to correct results?

A few years ago a writer in the JOURNAL argued that when several theories are advanced to explain the same phenomena, economy of thought demands that all but one of these theories be abandoned, unless each of the several theories possesses distinct advantages not possessed by the others. He then proceeded to make a misapplication of the revolving-field theory, and as his deductions naturally were in error he concluded that the revolving field theory is more liable than the cross-field theory to lead to erroneous results. He also was laboring under the delusion that the revolving-field theory is not applicable to commutator motors, and therefore advocated that this theory be abandoned in favor of the cross-field theory.

The present writer's opinion is that the point of retaining, in the interest of economy of thought, only one theory to explain a certain set of phenomena, is well taken; but I can not agree that in this case the revolving-field theory should be abandoned. My preference for the revolving-field theory is that is appears to be the more general one of the two. If the two components of the revolving field are equal, we have a single-phase system; if they are unequal, we have an unbalanced polyphase system. If one component vanishes, we have a balanced polyphase system, and if the angular velocity of the rotating field is equal to zero, we have a direct-current system. In other words, all phenomena of rotating electrical machines can be explained as special cases of the general theory based on two oppositely rotating magnetic fields.

H. R. West: I agree with Mr. Alger that the best method of calculation is that which gives results of the necessary accuracy, and no more, with the least amount of labor. On the other hand, I cannot accept the statement that the methods of calculation that I have given are very complicated. The greater part of the work of calculating a motor is contained in the tabulated part. Examination of this tabulated part of the calculation will show that nearly all of the rows of numbers are obtained with only one setting of the slide rule, or merely by addition. With a very little practise, one will find that the calculation can be carried through very easily and quickly. The method given for the single-phase induction motor has been compared in actual trial with the most up-to-date methods of accurately calculating the polyphase induction-motor characteristics, and although it has been found to be somewhat more laborious, as obviously it must, since the operation of the single-phase, induction motor is very complicated in comparison to that of the polyphase motor—still it is found to be comparable in the amount of work and time required. Furthermore, anyone who can use a slide rule can carry out the calculation completely. It is not necessary for him to know anything about motors or electric circuits in order to carry out a complete calculation.

There are some very obvious approximations that can be made in the calculations, particularly in calculating the constants F_n and G_n. These approximations would result in very little more than an apparent reduction in the labor of calculating, and therefore the expressions were given in full for the sake of completeness.

As Mr. Alger suggests, a systematically arranged calculation form would probably be found equally helpful in calculating the characteristics of a motor from equations that might be derived by the revolving-field method. However, I do not believe that the revolving-field method of analysis will lead as directly to equations or formulas that are most useful for calculation purposes.

Mr. Hansen calls attention to the terms in my equations that represent the speed voltages corresponding to the rotor leakage fluxes. The inclusion of these terms is not new[2] with the author, although they have been neglected by some writers, generally with only very slight effect on the accuracy of the results.

The correctness of the results that have been obtained by the cross-field method of analysis has been questioned by Mr. Hansen. The exact equivalence of the results obtained by the revolving-field and cross-field methods was demonstrated several years ago[3]. Furthermore, examination of the analytical expression which Mr. Hansen derived for the line current taken by the single-phase induction motor in his very instructive paper[4] on the rotating-field theory will show that his equation is exactly equivalent to the corresponding one of my paper.

Reply to the remaining portions of Mr. Hansen's discussion must consist largely of repetition of the ideas expressed in the opening paragraphs of my paper. Both methods have their own advantages, depending partly on the types of motors. For instance, it is obvious that the revolving-field method should be used for the balanced polyphase induction motor, and the cross-field method should be used for the a-c. series motor. At the same time, I believe that a study of both of these motors from both points of view will often be found worth while. In the case of the single-phase induction motor, which seems to offer the most debatable ground in regard to the cross-field and revolving-field methods, it seems that the revolving-field method is much superior for the purpose of giving a mental picture of how the motor works. At the same time, I have found that the cross-field theory adds to and clarifies that picture. On the other hand, I am convinced that the cross-field method of analysis is more useful for exact analysis, since it leads directly to results that are immediately useful for exact numerical calculation without the necessity of making two separate calculations for a polyphase motor and then combining them.

As Mr. Alger has pointed out, there seems to be only one case in which the revolving-field method can be used and where the cross-field method cannot be used, *i. e.*, where the rotor inductances depend upon the frequencies. Otherwise, one method seems to be as general as the other.

The paper was not intended as an attempt to prove the general superiority of one method over another for any particular motor, but to demonstrate the possibility of using the cross-field method of analysis to obtain readily usable, accurate, numerical methods of calculation of motor characteristics. My experience leads me to believe that such methods of calculation can be most readily derived by the use of the cross-field method, in the case of many kinds of motors, particularly single-phase motors.

DEVELOPMENT AND APPLICATION OF LOADING FOR TELEPHONE CIRCUITS[5]

(SHAW AND FONDILLER)

NEW YORK, N. Y., FEBRUARY 9, 1926

Bancroft Gherardi: The invention of loading and the development of telephone repeaters have, together, revolution-

ized the engineering of toll-line plants in the United States. For the invention of loading we are indebted to Dr. Pupin.

Before loading was invented, cable was to toll-telephone transmission much the same as strychnine is to the human system. Any great amount of cable produced definitely unfavorable reactions. The advent and application of loading produced a substantial change in this situation. Whereas, before loading was available, a toll-line cable of even twenty or thirty miles in length presented a serious problem which could only be solved by the generous use of copper, loading very much extended the range of cable so that practical toll cables of even 200 mi. length were available. With the advent of telephone repeaters and their use in combination with loading, toll cables 1000 mi. in length or even longer became practical and economical.

Today we are giving commercial telephone service regularly through cable between Boston and New York on the one hand and Chicago on the other. Before the end of 1926 New York and Boston will be connected by an all-cable route to St. Louis. From Boston to St. Louis it will be about 1400 mi. following the route of the cable.

Many other important cable routes are completed or now under way so that within a few years the principal toll routes in the northeastern section of the United States will be cable.

There are several advantages in this type of construction. On the more congested routes right-of-way problems would have been formidable without cable. Between New York and Philadelphia, by the end of this year we would have required twenty 60-wire pole lines to take care in overhead construction of the circuits that we shall have in cable. The maintenance of these lines under unfavorable conditions would have been a formidable problem.

To some, it might appear that the loading coils and repeaters would necessarily be a somewhat incidental factor in the total amount of construction involved in the toll-line cable. This is not the case. Considering a cable between New York and Chicago, it is found that only about 50 per cent of the total cost of the cable is in the cable itself and the structure supporting it.

F. B. Jewett: In looking over the paper and in casting my mind back over the history of my connection with the telephone business (which is in point of time almost coincident with the span of time in which loading has been a factor) I was interested to recall the several steps through which this whole art of loading has gone from the days when it was first presented through Dr. Pupin's work. My mental review included the early stages of our attempts to use loading up to the present time when it is recognized as a factor of very great importance.

I chuckled to myself as I thought of a time, nearly twenty years ago, when we thought our development work as applied to loading was nearing completion. The word went out that we ought to hustle up the work we then had in hand and button up this loading development so that it would be standard for all time and we could take our forces off and go to other things. Well, just as in the case of all things of an engineering nature which have real continuing merit, so it is in the case of loading. Being a real thing, there is no end to the development work and the field of application continues to grow. As the paper states, there are more men engaged in loading development problems today than there ever were in the history of the work; also the problems which open up before us as possible of solution through loading and the combination of loading with repeaters, are more extensive now than they ever have been in the past.

As a result of the work to date, which has resulted not only in improvements in kind but in cheapening the forms of loading, we are continuing to reduce the size and length of circuits on which it is economical to apply loading. At any given stage of the development of a thing like the loading coil, there comes a time when although physically possible of use on certain kinds of circuits, it is economically not feasible to use it because it is cheaper to get the desired result in some other way. But, with the cheapening of loading coils and their improvement, the gage and length of circuits on which loading is commercially applicable and advantageous have been reduced until we are approaching the point where it would appear to be economical to use loading on wires as fine as it is mechanically possible for us to employ them.

As the paper indicates, the development work started by the requirements of loading per se, has ramified in all sorts of unexpected nooks and crannies. It has expanded to include electrochemical processes, matters of tool design for the utilization of those enormously powerful presses for forming the core material, special machinery for winding coils, the kinds of insulating material, a thousand and one things which you wouldn't ordinarily think of as being connected with loading-coil developments. Loading-coil developments have also had profound effect on the methods of line construction. The precision with which we have to space these coils, the accuracy with which we have to maintain the balances between the parts of a circuit and the circuits themselves—all of these things indicate what a vast engineering field has grown up as a result of this thing which appeared relatively so simple.

Just one point in closing: I have no statistics to give but will mention one interesting calculation to indicate what the traffic possibilities are in a group of circuits of modern structure, equipped with loading coils and with modern repeaters. Mention has been made of the New York-Chicago cable. That cable in the main, as far as I know, is a cable of standard size. That means it is a cable which has an outside diameter of 2⅝ in. The lead sheath is ⅛ in. thick and inside there is a core of paper-insulated wires. It is primarily a telephone cable. Just as an illustration, let us consider what the communication-carrying capacity of this telephone cable would be if it were used just as it stands for telegraph purposes instead of telephone. With the voice-frequency multiplex system, it is possible to obtain about ten telegraph channels per telephone pair. If each of these telegraph channels were equipped with multiplex printing telegraph apparatus commonly used by the Western Union Telegraph Company, we could operate about ten thousand printer circuits in each direction. Working simultaneously at their normal speeds, it would be possible with this set-up to transmit between New York and Chicago the whole contents of a New York daily newspaper, exclusive of advertising material, in less than two minutes.

M. I. Pupin: The authors mentioned that it is convenient to discuss the coil-loaded line in terms of its corresponding smooth line. I should like to add one word to that statement —that it is still convenient—because I discussed it that way twenty-six years ago, in my first paper before the American Institute of Electrical Engineers. They also say that "Professor Pupin gave his famous solution in a paper presented before the Institute in May, 1900." That is a very complimentary statement but I should like to see that compliment completed. I should add that in that paper was also given the fundamental mathematical method of treating networks, filters and balancing networks. Before that time no one knew anything about it. They call them filters in West and Bethune Streets. At Columbia University we call them pilot conductors. But they are more persistent than we are, and so they have their own way. But the theory of the filters was first given at Columbia University and not at West Street.

Now, having said all the disagreeable things that I can think of, I am going to add another one which is not so very disagreeable perhaps, or perhaps more so. They talk of the loading coil, the toroidal loading coil. There is a very, very important bit of history attached to that. When I came out with the toroidal form of the loading coil, the engineers of the American Telephone & Telegraph Company couldn't see any virtue in it at all. It took them some time to recognize its virtues but when they did, they recognized them very clearly. Since that time they have been eliminating all other forms of coils that they

employed by the hundreds of thousands in their business.

Now I won't be disagreeable any more. The work that that company has done upon the development of the toroidal coil (invented at Columbia University and not in Bethune St.) is most remarkable. The development went on with a steady progress until today they have a coil that represents scientific research efforts perhaps unequalled by anything else that has happened in the telephone art during the last twenty-five years, since I made the invention.

It is a remarkable result and I think by next year they may have another announcement to make which will be even more remarkable than anything else they have announced so far, but I am not at liberty to talk about that.

It goes without saying that, in the course of the development of an invention, other things are brought in to supplement the invention and it speaks very highly for the loaded telephone cable that it is supplemented so beautifully by the telephone repeater of the vacuum-tube type. A fellow who can't associate with anybody else is not a very good fellow as a rule. An invention that can't stand the companionship of other inventions is probably a poor invention. The loaded-conductor invention takes the repeater invention into its arms and they hug each other and make a beautiful pair of congenial companions. That to me is more encouraging and more complimentary to the loaded-conductor invention than anything else that has happened. Attempts have been made to supplant the loading coil, to get along with repeaters only by adding attenuation equalizers, but they didn't prove practicable. This created the impression in places that the loaded-conductor invention was dead and a friend of mine came to me one day and repeated a sentence which I published in a book some time ago: "Inventions grow old and are superseded by other inventions."

Some one once said to me, "Isn't that a sad expression, Professor? Doesn't that indicate that your invention is dead?"

That doesn't refer to my invention at all. If it did I wouldn't have put it there. It would betray too much disappointment and I dislike exhibitions of disappointment. No, the invention is not dead; it is still alive and quite vigorous.

It is very true, as Mr. Shaw has said, that not even a very small fraction of the hundred million dollars is in my pocket. Anybody can see that; and it isn't in the pockets of the Telephone Company either, which is not quite as obvious. It is in the pockets of the people of the United States, where it belongs, and they will get a great deal more in their pockets in the course of time, because every year the combination of loading and telephone repeaters is saving an enormous amount of money to the people of the United States. And what is it producing? It is producing an effect for which Washington and Lincoln longed. Washington thought of nothing so much as of the consolidation of the American Union. Lincoln, much against his will, even went to war for the purpose of saving that Union and consolidating it.

Now when you hear of that beautiful telephone system, from Boston to New York, to St. Louis and to all the big centers in the United States, tell me of something else that has that power of consolidating the American Union! There is nothing else unless it be the radio broadcasting. That is another electrical art but that is not a part of the paper.

Who has produced this wonderful art which is producing this wonderful effect? I read another passage from my book: "It is not so much the occasional inventor who nurses a great art like telephony and makes it grow beyond all our expectations as it is the intelligence of a well organized and liberally supported research laboratory," like the Bell Telephone Laboratories at West and Bethune Streets, which I have been abusing so much.

The industries of this country have finally discovered the correct method of doing things. Their great research laboratories take the more or less crude ideas of individuals and develop them and put them together as the American Telephone and Telegraph Co. has put together the loaded conductor and the telephone repeater. This is creating one of the finest telephonic systems that the world has ever known, and has gone far beyond our expectations.

The paper testifies to that better than anything I have seen.

William Fondiller and Thomas Shaw: Dr. Jewett has referred to the early stages of loading development work, and recollected that it was thought at that time that loading was to be standardized for all time so that the engineers might give their attention to other problems. While such a consummation may have appeared very desirable to some at that time, new developments in materials and processes and in methods of operation continually open up new fields of investigation and design. Our paper has attempted to chronicle the major steps in this development.

In considering Professor Pupin's discussion, the authors very much regret that he appears to feel that they have not fully recognized his contributions to this art, and that as a result of this has made several remarks which he designates as "disagreeable things."

The paper refers to Professor Pupin's famous solution of the coil-loaded transmission line. It is so generally known that it hardly requires repetition that Professor Pupin obtained the fundamental patents on the coil-loaded line and the toroidal form of loading coil.

As stated at the beginning of the paper, this does not attempt to cover the origin of loading or the early developments of the art, as these have been treated quite fully in earlier papers, particularly Mr. Gherardi's 1911 paper before the Institute. The loading-coil invention, as was true of Bell's original invention and as is true of nearly all important advances ,was not without its controversies. This is similarly true of the developments in filters and balancing networks which Professor Pupin also mentions. Any reference to these past controversies is entirely aside from the purpose of the paper.

Now, about that part of Dr. Pupin's discussion relating to the beautiful companionship of the loading invention and the repeater invention, a casual reading of the paper may lead one to infer that the application of repeaters to loaded circuits was easily accomplished. Be it understood, however, that the paper is a statement of end results, rather than a detailed account of the difficulties which had to be overcome to reach these results; in fact a great deal of investigation was required, extending over a number of years, before it was commercially possible to combine phantoming, loading, and repeatering telephone circuits. A study of the line characteristics indicated that the failure of the early types of loading coil to maintain the necessary stability was principally responsible for the inability of the repeaters to get along with the loading coils. Development of new magnetic materials and improved construction methods were required before these obstacles were overcome.

METHODS OF HIGH QUALITY RECORDING AND REPRODUCING OF MUSIC AND SPEECH BASED ON TELEPHONE RESEARCH[1]

(Maxfield and Harrison)

New York, N. Y., February 9, 1926

C. R. Hanna: The following discussion applies particularly to that part of the paper dealing with the reproducing mechanism. The relative merits of the several improvements that were made are not clearly brought out in the paper and it is the purpose of the writer to compare the importance of the various developments.

In listening to reproduction from one of the new-type phonographs, the average person is impressed with just two things; first, the apparent greater volume of sound, and second, the great improvement in the response at low frequencies. The greater volume of sound is due partly to the fact that there are more low frequencies present, and perhaps, in a measure,

1. A. I. E. E. Journal, March, 1926, p. 243.

to the fact that the diaphragm is one which acts like a piston, causing a greater volumetric rate of displacement of air into the horn for a given needle velocity than with the old type of flat diaphragm.

The improvement in the low-frequency characteristic of the reproducer, as described, could not have been obtained without the use of the slowly expanding logarithmic or exponential horn. The authors refer to the work of Arthur Gordon Webster in this connection: the general properties of the exponential horn were given in his National Academy of Science paper of 1919. Webster did not, however, carry his work sufficiently far to show the properties which the authors have stated in their paper; namely, that the exponential horn is a uniform radiator of sound down to a certain frequency, known as the cut-off frequency, which is determined by the rate of increase of section and the area of the large end of the horn.

The authors cite some work (as yet unpublished), by Messrs. Flanders and Thuras, in which these properties are shown both theoretically and experimentally. I desire to call attention to the fact that the paper by Hanna and Slepian on "The Function and Design of Horns for Loud Speakers"[2] showed these same properties for the exponential horn. The equation for such a horn is

$$A = A_0 \epsilon^{Bx}$$

where

A = Area at any point

A_0 = Initial area

x = Distance from initial area, cm.

B = Constant which determines the rate of increase. It was demonstrated that the cut-off frequency is determined by the relation

$$\frac{2\pi f}{B} = \frac{a}{2}$$

where a = velocity of sound. From this it is seen that the smaller B is, the lower will be the cut-off.

The radiation characteristic of the infinite exponential horn

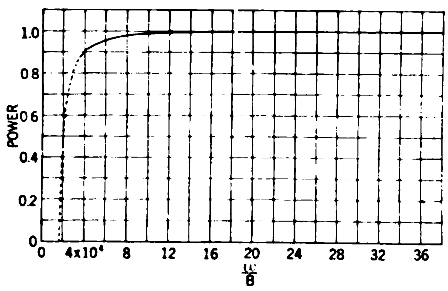

Fig. 1

for a fixed velocity of air in its throat was also shown in the paper by Hanna and Slepian. Fig. 1, herewith, shows this curve. The abscissas are $\frac{\omega}{B}$ and the ordinates give the comparison between the exponential horn and the infinite straight pipe which is a uniform radiator down to zero frequency. The cut-off point is seem to be as stated above.

It was clearly brought out in this paper that an exponential horn could be made with much smaller dimensions than any other shape of horn giving equal performance. A comparison was also shown between a particular exponential horn and a conical horn of equal length and terminal dimensions. This is given in Fig. 2, the superiority of the exponential horn being quite pronounced. Up to this time many persons had advocated the conical horn. It is believed that this paper was the first to show the superiority of the exponential horn.

2. A. I. E. E. Transactions, 1924, page 393.

Now, taking up the matter of the final or large area of the horn, as is pointed out by Maxfield and Harrison, if this area is large enough to prevent end reflections in the range of frequencies where the horn is a good radiator along its length, a horn will be secured which has very little resonance. The curves of Fig. 3 were presented by Hanna and Slepian to show the variation of reflection with frequency and area. The curves indicate that the smaller the area and the lower the frequency, the greater will be the reflection. It is seen, however, from the curve for

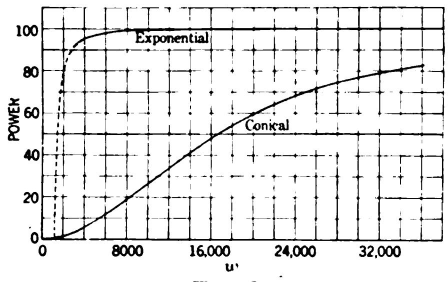

Fig. 2

the largest area, that the reflection becomes appreciable only in the range of frequencies where the horn ceases to be a good radiator along its length. Hence it follows that a horn of this shape can be designed with no marked fundamental resonance.

The degree of horn resonance and the position of the cut-off frequency as indicated by Fig. 20 of the Maxfield and Harrison paper agree very closely with values that can be predicted from the curves of Figs. 1 and 3 in this discussion.

The very careful proportioning of masses and compliances in the mechanical system of the reproducer has played only a minor part in the securing of a more uniform frequency-response characteristic than in the older types of phonographs. The slight extension of the upper frequency range may be attributed to the accurate design of mechanical parts. It should be pointed out, however, that since the phonograph record is a constant-current (or velocity) generator, the impedance of the mechanical system does not have to be uniform over a wide band of frequencies for it to be forced to vibrate in accordance with the vibrational velocity of the record. A departure from this fact, not apparent from the electrical analogy given by the authors in their paper, is the ability of the whole arm of the reproducer to vibrate in the low-frequency ranges instead of just the diaphragm mechanism. This may be overcome either by increasing the mass of the arm or, as the authors have done, by reducing the stiffness of the diaphragm.

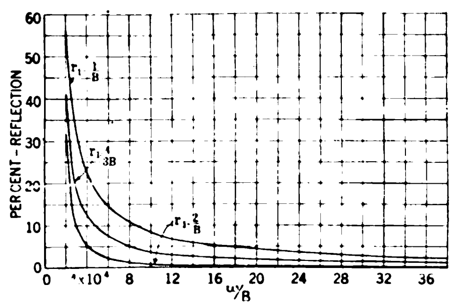

Fig. 3

Great credit is due the authors for the design of a mechanical system which is light and resilient, enabling the needle to track the record with small reaction force (and consequent decrease in wear) at the high frequencies where the accelerations are great, and at low frequencies where the deflections are great. The big improvement in the quality of reproduction, however, is due to the use of an exponential horn whose rate of increase

of section is very small and whose final section is quite large.

E. W. Kellogg: I think most of us have thought of the rocking arm, which connects the needle with the diaphragm in a phonograph, as a simple lever, rigid enough so that when the needle moves one way, the diaphragm moves the opposite direction by a corresponding amount. If we could see what is really going on during a high-frequency vibration, we should probably find that the motion was more nearly like that of a snake. Messrs. Maxfield and Harrison and their associates have accepted the wave-motion picture and based their design upon it. The most striking resultant change in design is the interposition of a flexible link, or spring, between the end of the lever and the diaphragm. On first thought, it seems like deliberately throwing away some of the available motion, but the result is quite the opposite. I refer to the spider through which the diaphragm is driven.

If telephonic currents are to be transmitted without distortion over a high-efficiency line of length exceeding a sixth of a wavelength for the highest frequencies, the line must end in a non-inductive resistance of a definite value. A corresponding resistance is required in a mechanical system. In the case of the reproducing system the required resistance is obtained from the sound radiation of the diaphragm. But for the cutting tool, some other resistance must be found. In an electrical circuit nothing is easier to get than resistance, yet its mechanical counterpart is by no means easy to obtain. Sliding friction is not at all suitable. Motion in viscous fluids and electromagnetic drag, such as used in wattmeters, are true analogs. I wish to draw an illustration from the case of electromagnetic drag. An aluminum ring, weighing about four grams, surrounds a magnet pole, so that it is in a radial field of about 10,000 gausses. If one pushes it up and down, it feels as if it were in thick molasses. Under its own weight it settles about one millimeter per second. Yet if this ring is vibrated in an axial direction at 4000 cycles, its mass so predominates over the resistance that the power factor is only about 40 per cent. Mechanical hysteresis is another means for absorbing energy from vibrations. Rubber has long been used for such purposes. But rubber, so far from being pure in mechanical resistance, is a spring with a power factor of only about 10 per cent. I think the authors of the paper are to be complimented upon the ingenious device by which they obtain with the use of rubber a practically pure resistance with which to load the cutting tool. It should be borne in mind that the damping required for the cutting tool is of an altogether different order of magnitude from that which many of us have employed to take out the resonance peaks from loud-speaker diaphragms and similar applications.

The paper mentions methods of measuring mechanical impedances. I should be much interested to hear something further of the means used, for the problem presents many difficulties, and the results of such measurements would find many applications.

One statement in the paper causes considerable surprise. The knife edge was discarded because it has too great an elastic yield, and because it brings in too much rotational friction. The knife edge, of course, must work with an initial pressure exceeding the maximum force on the bearing, due to the vibrations, and is not well adapted to stand forces in more than one direction, but, in the case of the pivot for the reproducing lever, one would expect a well designed knife edge to work very satisfactorily.

L. T. Robinson: I am in agreement with the statement of the authors that, "There is therefore no distortion in the record whose purpose is to compensate for errors in the reproducing equipment." In employing so many elements, some of which can be so readily modified in performance the temptation is very strong to look only at the final result and not be too critical as to where any corrective treatment is to be administered. I hope the stand taken by the authors will be firmly adhered by them and others who are working along similar lines. In this way, any progress that has been made, or will be made, becomes permanent.

Speaking of the electrically-cut record in general, we need not, for the moment, be concerned with minor details of the process. The results already obtained are so good that we may feel sure that the electrically cut record has come to stay and will place the phonographic art on an entirely new plane of excellence.

The mechanical reproducing system described by the authors is a distinct advance over former phonographs. However, I feel that full realization of the advantage of the electrically cut record will come through electrical reproduction.

One great advantage of the electrical method of reproducing is that the control of the sound volume is obtainable quite independent of the cut on the record and the cut on the record is controllable with consideration for the best conditions for the record alone. The advantages of such separation can be learned from the paper if it is read with this point in mind.

Volume of the sound reproduced is quite important and reproduction to be quite satisfactory must be about equal to the volume of the original sounds. A loud tone produced on a given musical instrument is quite different from a soft tone produced on the same instrument and reproduced with larger volume.

A. E. Kennelly: We have here presented to us the wonderful analogy which underlies mechanical and electrical phenomena, with mechanical phenomena interpreted in electrical terms.

We have long known that mechanical inertia was really electrical, and now we are finding that all these mechanical phenomena are primarily electrical quantities.

J. P. Maxfield: There are one or two technical questions brought out in Mr. Hanna's discussion which are of interest: The first deals with the statement that the new reproducing mechanism has a greater apparent volume of sound. In this connection, it is interesting to note that the response curves of the new and the old machines shown in Fig. 20 indicate that in the frequency region from around 800 to 2000 cycles per second, the old machine produced a louder sound for a given needle velocity. It will be seen, therefore, that this apparent increase in volume has been obtained by the widening of the band reproduced rather than by increasing the amount of energy radiated in that frequency band in which the old machine was most efficient.

The other point of interest refers to his statement that "The very careful proportioning of the masses and compliances in the mechanical system of the reproducer has played only a minor part in the securing of the more uniform frequency response characteristic than in the older type of phonograph." In view of the high quality which is obtained and of the commercial requirement that the wear on the record shall not be excessive, the authors do not agree with this statement. It is not necessarily true that because the record is a constant-current generator and, therefore, delivers constant current to the sound-box mechanism, that the diaphragm necessarily delivers constant current to the air. If a relatively stiff, heavy, vibrating system is used, it becomes exceedingly difficult with the constant-current type of generator to obtain good quality and if it is possible to obtain it, the wear on the record becomes excessive. A reference to Fig. 16 indicates that the first part of the system reached is the needle point which has a definite compliance. At the higher frequencies, if the impedance of the reproducing system is too high, the needle will bend instead of moving the rest of the system and the response will be reduced thereby. Similarly, at the low-frequency end, if the diaphragm-edge compliance is too small, that is, if the diaphragm is too stiff, the whole tone arm will vibrate and thereby reduce the motion of the diaphragm relative to its case. It is true that, so far as response is concerned, this effect can be corrected by increasing the moment of inertia of the tone arm—a method which is equivalent to increasing the mutual inductance of the transformer, T_1, (Fig. 16); but if the solution is thus obtained, the wear on the record becomes excessive and in some cases the force becomes so great that the needle will not track in the groove.

The solution presented in the paper is one in which the mechanical impedance has been made as nearly as possible independent of frequency and is of the nature of a pure mechanical resistance. The result of this type of solution is that a maximum of sound energy at all frequencies within the band is radiated with a minimum of wear on the record.

MECHANICAL FORCE BETWEEN ELECTRIC CIRCUITS[1]

(Doherty and Park)

New York, February 9, 1926

J. Slepian: The relation which is perhaps most frequently used by electrical engineers for calculating mechanical forces between circuits is that due to Maxwell, which states that in any displacement in which currents are kept constant, the mechanical work received during the displacement is equal to the increase in magnetic energy of the system. This relation is readily derived from the principle of conservation of energy by taking into account the electrical input during the displacement. As Professor Karapetoff puts it, there is a "fifty-fifty" rule here; half the electrical input goes to increasing the magnetic energy and half is given up to mechanical work.

However, this fifty-fifty rule does not apply when there is iron in the neighborhood, subject to saturation, and Messrs. Doherty and Park do well to bring out this fact strongly. In my own experience I have seen several cases where this rule led to completely erroneous results when applied to practical machines. In one instance, a complete change in sign of the force was involved, a repulsion was predicted, whereas actually an attraction was found. The magnetic circuit shown in Doherty and Park's Fig. 1 is one for which application of the fifty-fifty rule would give the wrong sign if the iron is saturated. With constant current, motion of the armature upward *decreases* the magnetic energy, and yet, the armature is attracted and not repelled.

The great contribution of Doherty and Park in this paper lies in showing that application of the principle of conservation of energy in another way leads to a relation which is universally applicable, saturation or no saturation. Namely, if the mechanical displacement is effected, not with constant currents but with constant flux linkages, then the mechanical work received is equal to the *decrease* in magnetic energy. The authors further add to the value of this result by showing how the calculation on this basis may be carried out, when the curves connecting flux linkages with currents for various positions of the moving parts are known.

I have a suggestion to make as to the formulas *(9)* and *(11)* which the authors give, and the corresponding expression for magnetic energy. While it is principally a matter of notation, I think it is important because it makes such a difference in the clarity of ideas. For simplicity, considering only two circuits, the authors would write the magnetic energy,

$$E = \int_0^{\Omega_1} i_1 \, d\,\omega_1 + \int_0^{\Omega_1} i_2 \, d\,\omega_2$$

To bring out more definitely that i_1 and i_2 are functions of both variables, w_1 and w_2 I shall write this as

$$E = \int_0^{\Omega_1} i_1 (\omega_1 \, \omega_2) \, d\,\omega_1 + \int_0^{\Omega_2} i_2 (\omega_1 \, \omega_2) \, d\,\omega_2$$

Now ω_2 is not a constant in the first integral, but may be varied as ω_1 varies, and ω_1 is not a constant in the second integral. However, whatever relation is adopted between ω_2 and ω_1 in the first integral, the same relation must be used in the second if the correct value for magnetic energy is to be obtained.

Now integrals of this kind are of frequent occurrence in mathematical physics, and they are usually denoted by line integrals written thus:

$$E = \int_{\substack{\omega_1 = 0 \\ \omega_2 = 0}}^{\substack{\omega_1 = \Omega_1 \\ \omega_2 = \Omega_2}} i_1 \, d\,\omega_1 + i_2 \, d\,\omega_2$$

This single integration is to be carried out over a curve in the $\omega_1 \, \omega_2$ plane, joining the point $\begin{pmatrix} \omega_1 = 0 \\ \omega_2 = 0 \end{pmatrix}$ to point $\begin{pmatrix} \omega_1 = \Omega_1 \\ \omega_2 = \Omega_2 \end{pmatrix}$.

In general, the value of such a line integral depends upon the path chosen in going from the initial point to the final point, but in this case since the magnetic energy is the same, however the state $\begin{pmatrix} \omega_1 = \Omega_1 \\ \omega_2 = \Omega_2 \end{pmatrix}$ is reached, the integral is independent of the path. Mathematicians have shown that in this case it follows that

$$\frac{\partial\, i_1}{\partial\, \omega_2} = \frac{\partial\, i_2}{\partial\, \omega_1}.$$

This may be looked upon as a generalization for the case of saturation, of the well-known fact for the linear case, that the mutual inductance of circuit No. 1 upon circuit No. 2 is equal to the mutual inductance of circuit No. 2 upon circuit No. 1.

On the fourth page first column of their paper, the authors give a number of formulas applying to their Fig. 1, and state that the quantity L_0, which appears there, is the inductance corresponding to no saturation. However, in their derivation of these formulas, if I understand their derivation correctly, L_0 is taken as the inductance corresponding to the air gap alone. That is, L_0 is the inductance corresponding to infinite permeability, and not to no saturation. There thus seems to be an omission in the authors' proof, which might be rectified as follows.

Let

L_0 = inductance corresponding to air-gap alone: *i. e.* inductance corresponding to infinite permeability.

Let

L_0' = inductance corresponding to no saturation,

Let

L_1 = inductance corresponding to iron alone with no saturation, *i. e.*, inductance with zero air-gap and no saturation.

Then,

$$\frac{1}{L_0'} = \frac{1}{L_0} + \frac{1}{L_1}$$

Hence, since L_1 is constant.

$$\frac{\partial}{\partial\, x}\left(\frac{1}{L_0'}\right) = \frac{\partial}{\partial\, x}\left(\frac{1}{L_0}\right)$$

Hence, since L_0 appears in the authors' formulas only in the factor

$$\frac{\partial}{\partial\, x}\left(\frac{1}{L_0}\right)$$

Therefore L_0' may replace L_0 throughout.

R. H. Park: In order to test the ease of applicability of the formulas developed and the agreement of calculated and observed results, a calculation and test was made in a particular case.

The circuit employed (see Fig. 1 herewith) consisted of two magnetic yokes separated by a brass strip and excited by direct current in two coils connected in series.

In order to determine the attractive force of the yokes, a weight was attached to the lower yoke and the exciting current was reduced until the yokes separated.

In order to calculate the force, the flux linkages ω were measured with a ballistic galvanometer for different air-gap and excitation. This data are shown in Fig. 2.

From the saturation curves, the curves of $\frac{\partial\, i}{\partial\, x}$ at constant ω were computed (see Fig. 3) as outlined in the paper. The forces were then calculated from the areas under these curves.

1. A. I. E. E. Journal, March, 1926, p. 231.

The agreement of observed and calculated results is shown in Fig. 4. The smooth lines in the figure represent the calculated, and the small circles, the observed results.

The difference between observed and calculated results is about 4 or 5 per cent, the observed results being, in general less than the calculated. The tendency for the observed results

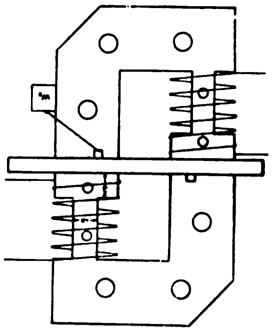

Fig. 1

to be low may be accounted for by unavoidable disagreement in the positions of the center of moment of the load and of the attractive force resulting in less effective magnetic pull, or by the effect of vibration.

From a theoretical point of view, we know that, until the satura-

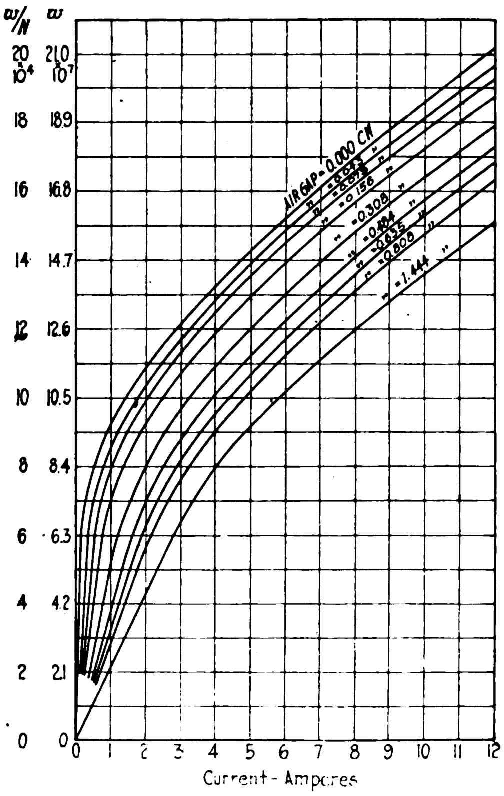

Fig. 2

tion of the core is sufficient to change appreciably, the distribution of the field in air, the curves of $\frac{\partial i}{\partial x}$ should be linear.

It may be observed that the experimental results agree with this requirement, the curves of $\frac{\partial i}{\partial x}$ being linear except at very high saturation.

This fact indicates that the approximate expression for force [equation (65) of the paper] holds good in this case until extremely high values of saturation are encountered.

Thus, the experimental results obtained agree with those theoretically deduced in the paper.

R. E. Doherty: The authors wish to thank Dr. Slepian for his

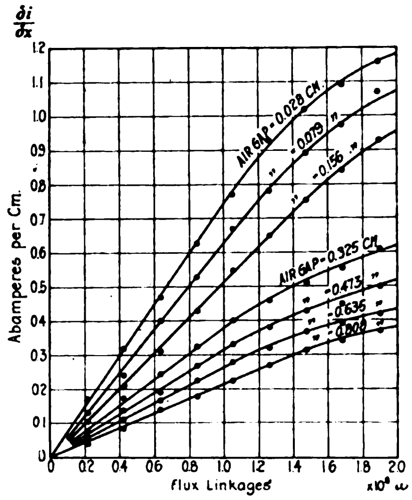

Fig. 3

suggestion regarding notation. It is undoubtedly a somewhat clearer representation of quantities than that used by them.

With respect to his other suggestion, however, the authors have not made the omission in logic which he alleges.

They have treated two different *special cases* where saturation

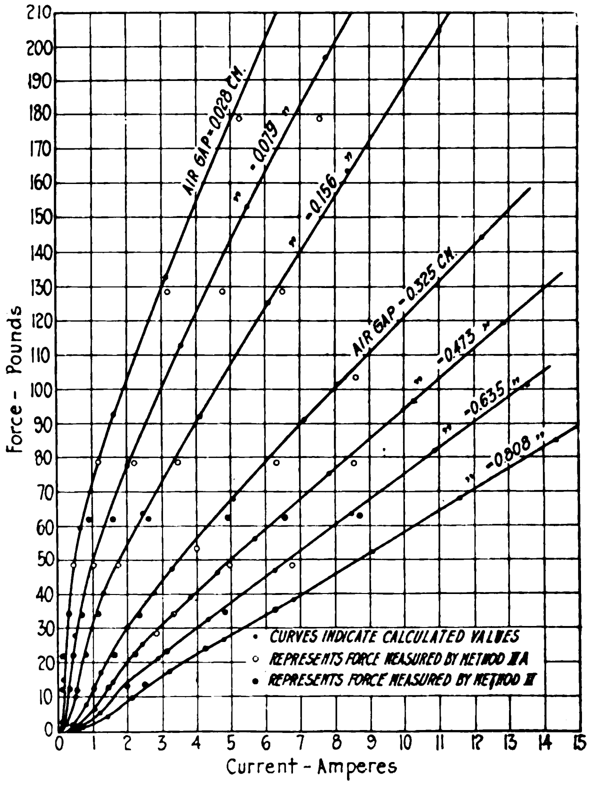

Fig. 4

is taken into account, and in the results of both cases, the term L_0 appears. The symbol L_0 is defined in the list of notations as "the self-inductance in henrys of a single circuit without satura-

tion," and it therefore, in general, includes the effect of the reluctance of the iron as well as of the air. Dr. Slepian's point is that the effect of the reluctance in the iron, when saturation is absent, is not taken into account.

The two cases treated are,

a. "Special Case," in connection with Fig. 3 of the paper. Here it is specifically stated that, so far *as* L_0 is concerned, the magnetic reluctance of the iron is neglected. Therefore L_0 in this special case in the industance corresponding to zero reluctance in the iron. Hence Dr. Slepian's discussion, referring to the equations based on this assumption, is not pertinent.

b. Another case, Appendix D, in which no qualifying assumption is made with respect to L_0 except those given in the definition, quoted above, from the list of symbols. And, therefore, if it is desired to consider the case which Dr. Slepian has in mind, he should use the equations for this case given in Appendix D.

PARAMETERS OF HEATING CURVES OF ELECTRICAL MACHINERY[1]

(KARAPETOFF)

NEW YORK, N. Y., FEBRUARY 10, 1926

G. E. Luke: As mentioned in this paper, Professor Kennelly derived the heating characteristics of an electric machine by considering it as one "chunk" of metal[2]. This paper gives the thermal equations on the basis of two "chunks" of metal (core and windings). An approximate solution of this problem based on three "chunks" of metal (core, windings, and frame) was given in another previous Institute paper[3]. As a matter of fact, a correct solution of this problem would have to be based upon an infinite number of "chunks."

Professor Karapetoff assumed two thermally connected masses of metal (core and windings), each having a uniform temperature and loss throughout. In practise, the losses and temperatures are usually much higher in the teeth than in the main part of the core; hence, there will be a heat flow in that direction. In the windings, there may be a considerable heat flow from the embedded part to the ventilated end portion. Thus, the heating curve of the "hot spot" on the copper will depend not only upon the thermal constants of the embedded copper and core but also upon the thermal conditions of the end windings. Again the large variation in the temperature of the cooling fluid in its passage through the machine will tend to cause all parts of the machine to vary with it.

The assumptions which must be made in order to derive the approximate thermal characteristics of a machine are more closely approached in small machines with relatively little forced cooling. On the other hand, in large machines, where long heat and fluid flow paths are found, together with a high velocity of the cooling fluid, the derivation of the heating characteristics on the assumption of uniform core and winding temperatures is likely to be erroneous.

The method of solution of the problem as simplified by Professor Karapetoff interested me, as several years ago I had occasion to solve the same problem. In my solution, θ_1 was evaluated from eq. (2) (also $d\ \theta_1$) and substituted in eq. (1). This also gave a linear differential equation having constant coefficients, but the second member, instead of being zero, as in eq. (8), was a function of p_1, p_2, k_1, k_2, s_1, and α, where α is the temperature coefficient of resistance. The solution of this was similar to eq. (10) with a constant term added. Although the method of solution given in this paper seems to be indirect, yet the equations representing the arbitrary constants are more systematic than the method I used.

1. A. I. E. E. JOURNAL, January, 1926, p. 40.
2. Temperature Rise of Electric Machines on Intermittent Duty, by G. E. Luke, *Electrical World*, May 27, 1922.
3. *Heating of Railway Motors in Service and Test-Flaor Runs*, by G. E. Luke, JOURNAL A. I. E. E., (1922), p. 165..

For the application of these equations, the author suggested that the many constants be calculated from experimentally obtained heating curves. The difficulty is to obtain accurate heating curves of the copper and iron temperatures especially on the rotating members.

I have applied these equations for predetermining the temperatures of machines on short-time overloads by calculating the constants from the known physical conditions. Thus, on such loads, most of the losses are stored and since the copper has such a high rate of loss, its temperature rises quickly. For example, the temperature rises of a 50-h. p., d-c. railway motor on a 150-per cent load, for one-half hour, as calculated (starting cold) were 51.5 deg. cent. armature core and 85.5 deg. armature copper, while the actual tested values were 48.0 and 87.5 deg. cent. respectively.

Another interesting application of these heating equations was to calculate the heating and cooling curve of a 600-volt, 31,000-cir. mil., rubber-insulated, stranded copper cable, with a

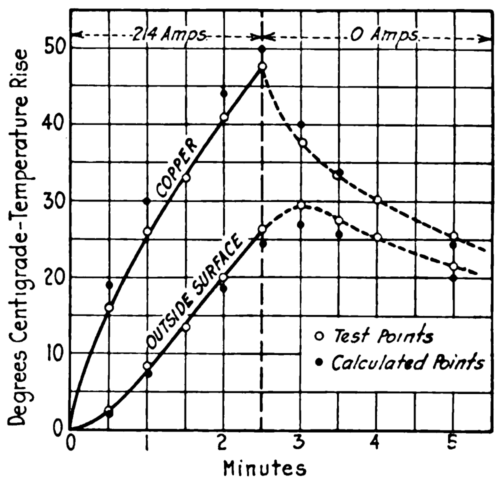

FIG. 1—HEATING AND COOLING CURVE OF A 600-VOLT, 32,000-CM. RUBBER-INSULATED, STRANDED COPPER CABLE

load of 214 amperes for 2½ min. The calculated points were based only on the weight of copper and insulation, the conductivity of heat of the rubber, and the surface heat transfer from the cable. The solution is necessarily approximate since the insulation and copper were assumed to have a uniform temperature θ_2 and θ_1, respectively. The results are given in Fig. 1 herewith. Since the loss in the rubber was zero, its slope was zero at the start of the cycle.

Although the assumption of two thermal masses simplifies the problem considerably, the final solution is still long and complicated and therefore will be used seldom by the average engineer. This solution should prove of value to the specialist, however, when considering problems such as I have mentioned. This solution also will indicate the limitations and errors of the less approximate solution based on a single uniform mass of metal.

W. F. Dawson: I want to show some curves (Fig. 2 herewith) that follow the curves given in Goldschmidt's paper[4] and also by Dr. Kennelly.

These curves are the heating curve of a mass of copper imbedded in insulation and other surrounding material. To simplify the problem, let us assume that it is not armature copper in an armature, but a field coil where the only loss is the copper loss. The initial rate of temperature rise depends upon the specific heat of the material, the specific gravity, (density), the specific resistance, and the current density. It so happens that, at 1100 amperes per sq. in., where there are no parasitic or extra losses, and the mean temperature is about 60 deg. cent., the rate

4. *Journal* I. E. E. (London) May 1905, Vol. 34, No. 172, p. 660.

of temperature rise is almost exactly one deg. cent. per min. This current density also gives approximately one watt per cu. in. (0.95 watt).

In practise, it is found that at 1100 amperes per sq. in., the initial rate of temperature increase is much less than one deg. cent per min., seldom more than one-half of a deg. cent. per min. and sometimes as low as one-third of a deg. cent. per min. The explanation lies in the fact that these windings are always surrounded with a considerable amount of insulation and frequently with masses of iron. Goldschmidt has suggested that the

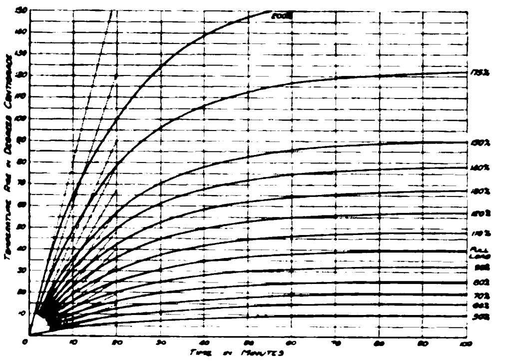

FIG. 2—TEMPERATURE GRADIENT CURVES BASED ON 2200 AMPERES PER SQ. IN., FULL LOAD AND TWO-DEG. RISE PER MIN.

specific heat of cotton insulation is approximately six times that of copper; hence it is easy to explain that the added thermal capacity of the surrounding insulation and iron is responsible for the lowered rate of temperature rise. A divisor of two is usually quite safe, hence with a current density of 2200 amperes per sq. in., one can safely assume that the initial rate of temperature rise will not exceed two deg. cent. per min.

I have made several tests with temperature rise plotted against time and found that, when a proper factor was used for the thermal capacity, the test results compared very closely with curves calculated according to Goldschmidt's formula. In one, a strange "hump" was shown in the observed heating curve and it was referred back to the testing department with the comment that "the phase currents in the armature became temporarily unbalanced." This was found to be the case. The extra heating was due to double-frequency currents induced in the field because currents in the armature phases became unbalanced. Fig. 2 will be found useful in the study of short-time ratings of windings, and the effect of fractional loads and overloads. It should be considered as a suggestion rather than something to be followed under all circumstances. It is plotted on the assumption that 2200 amperes per sq. in. gives an initial temperature rise of two deg. cent. per min. (this assumes that total thermal capacity equals twice that of the copper winding), that the final temperature rise will be 40 deg., and that the temperature rise varies as the square of the current load.

A little study will suggest many uses for curves of this sort; for example, a short-time overload is required on a machine that has been operating at fractional load until it has reached steady temperature. From the steady temperature indicated by the curve for that fractional load, follow the abscissa line to the left until it intersects the curve corresponding with the overload and note the corresponding time. Add the time for the required overload, and the intersection of the corresponding ordinate with the overload curve will indicate the total temperature rise.

C. J. Fechheimer: A few more words may be added in regard to the longitudinal heat flow in the copper. In machines which have, let us say, over 50-in. core length, the influence of the longitudinal flow upon the copper temperature at the middle of the core may be neglected. But in short machines, that flow plays an important part in the heat dissipation at the center. In some short machines, (say eight in. of core length or less), most of the heat generated in the copper is dissipated from the end windings, and there may even be flow of heat from the iron to the embedded copper whence it flows longitudinally to the ends. Frequently, then, there is not a great difference in temperature between the embedded copper and the ends.

It is well known that the time constant in a simple exponential equation is proportional to the ratio of the storage of heat to the dissipation of heat. In general, that time constant is considerably higher for the embedded part than for the ends, and, since there is so large an interchange of heat between the two in the short machine, the influence of the longitudinal flow cannot be ignored. About eight years ago I tried to obtain a solution of the problem, taking into account time and the distance along the conductors as independent variables. I obtained the partial differential equations and was able to integrate them. But the equations became so unwieldy when the terminal conditions were substituted that I abandoned the solution. I believe I still have the papers, and should be glad to send to Professor Karapetoff the results as far as I went, if he cares to go over them.

Suppose the time-temperature curves for a short machine are illustrated graphically as in Fig, 3 herewith. Curve I shows the rate of heating of the embedded part, and Curve II that of the

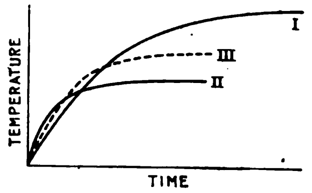

FIG. 3

ends, assuming that neither is influenced by the other. The actual time-temperature curve of the copper at the middle of the machine is about as in Curve III. The ends attain their maximum temperature in considerably less time than the embedded parts, each acting alone, and the maximums are quite different. If the equation of Curve III can be taken as of simple exponential form $[\theta = \theta_o (1 - \epsilon^{-\frac{T}{t}})]$, and if the final temperature rise θ_o and the initial slope $\left(\frac{d\theta}{dt}\right)_{t=o}$ be known, the entire curve can be plotted.

In Dr. Kennelly's paper of last year, and in this paper of Professor Karapetoff's mention is made of the similarity between the time equations of the heat circuit and the electric current containing inductance and resistance. In the discussion of a paper by Mr. Luke in 1922, that similarity was noted.[3] Perhaps that was brought to the attention of the electrical engineers long ago.

A. E. Kennelly: In the paper which I presented last year, I was not interested primarily in the determination of the conditions of heating, but in the presentation of the statistical factors concerning heating. As has been pointed out by several speakers, and as pointed out in the discussion last year, there are a number of instances in which the heating curves of parts of machines, or of parts of windings, or of core bodies, follow exponential curves,

and it is marvelous, I think, how common exponential curves, either of the rising type or of the falling type, are in natural phenomena.

We have been in the habit of referring the unit of time in which the exponential change occurs to a time constant in which the change is 63.2 per cent of the final ultimate change and in the next time constant 63.2 per cent of what again is left. That is a very awkward numerical calculation to present to practical men, so that, in order to avoid that unnecessary numerical and statistical combination, I ventured to point out that it is sufficient to take approximately 70 per cent of that exponential time constant (69.3 per cent theoretically) and to state that, as the binary time-constant or the time to come up to one-half; so that if in the first binary time constant of, let us say, twenty minutes, this element of the machine will come to half its final temperature elevation, then, in the next binary time constant of twenty minutes, it will come to half of what is left or three-quarters of the whole.

As has been pointed out by Professor Karapetoff and others, probably no machine develops a strictly exponential time curve of heating. As engineers, we try to find reasonable practical applications and we say, "Well, granted that it is never quite true, are there not cases which present themselves where the deviations for ordinary practical purposes can be neglected?" It is my opinion, after having gone over a considerable number of such heating curves, that many cases can be treated upon the basis of an experimental time constant.

So I think the procedure we can agree upon is this: Let us find the cases which present themselves in engineering practise where the actual curves are nearly constant, so that we may say, for practical purposes, that this machine, under such a load, will come up to one-half its final temperature elevation in so many minutes. Then one knows just how the heating will be beyond that point. Then, let us tabulate the exceptions.

I think we may look upon this as a valuable tool for the future, but I want first to see a tabulation of what can be done with existing machinery of various classes, using the simple, single time-constant. From what I have been able to ascertain from actual engineers,—men who are using this,—there will be a considerable number of cases where that does apply reasonably well.

F. Fabinger (in writing[5]): It may be of interest to call attention to my article entitled "A Contribution to the Theory of Heating of Electrical Machinery" published in the May 1923 issue of the *Elektrotechnicky Obzor* which is the official organ of the Association of Electrical Engineers of Czechoslovakia. In this article, I consider a body which is a source of constant quantity of heat per unit time to be completely surrounded by another body of infinite conductivity, in contact with a cooling medium of constant temperature. The differential equations in this case lead to a solution similar to Karapetoff's eq. (**10**); that is, the instantaneous temperature is expressed by a sum of two exponential terms.

Vladimir Karapetoff: As Dr. Kennelly has pointed out, the next step is to apply the proposed theory to a few machines to see how handy (or unhandy) it will be. I also hope that someone will be spurred to improve the two-chunk theory, but let us hope that this will be not in the direction of a three-chunk theory, but in the direction of distributed flow of heat.

To me, the next step is this: Assume the heat flow in the stator copper to be parallel to the shaft of the machine and the heat flow in the stator core to be radial. The temperature at a point will then not only be a function of time, but of the coordinates of that point as well, so that, as Mr. Fechheimer has pointed out, we shall have equations with partial derivatives. It would be of considerable interest to establish such equations. Even should they prove to be too complicated for a straightforward solution, some approximation methods may be applicable in numerical cases.

5. From Prague, Czechoslovakia.

ILLUMINATION ITEMS

By Committee on Production and Application of Light

SMALL CORONA LAMPS

Gaseous conductor lamps have been produced by D. McFarlan Moore for service on 115-volt circuits and in sizes smaller than those heretofore developed. They are now available in two sizes, illustrated in the accompanying cut, for operation upon 115-volt circuits, a-c. and d-c.

The lamps are understood to be filled with neon, argon and helium in certain proportions. When excited by electric pressure, the gas becomes luminous at the cathode. On direct current, the gas around one electrode glows. On alternating current, the gas glows at both electrodes.

The round bulb lamp, which is little more than an inch in diameter, consumes approximately 1/10 watt with an efficiency of the order of ¼ lumen per watt. The small tubular bulb lamp consumes about 1/50 watt.

These lamps, because of their low illuminating power and low efficiency, are not employed for purposes of illumination but possess value as markers and signal lights. By reason of practically instantaneous lighting and extinction characteristics they possess peculiar value for stroboscopic use. This type of lamp is employed in successful experimental transmission of motion pictures.

At the Annual Convention of the Institute at White Sulphur Springs, in discussion of these lamps, it was suggested that one field of application for them lies in their use as signal lamps on motors for direct drive in industrial work where 220-volt supply circuits necessitate the use of 220-volt lamps which oftentimes are not easily available.

EYESIGHT CONSERVATION

The investigation of school architecture and construction showed that defective illumination of classrooms has an adverse influence on the activity of the intellectual processes of children.

The investigators, according to the report of the Eyesight Conservation Council, studied the relative value of daylighting and artificial lighting, concluding that "owing to the manner in which the human eye has developed during many ages under natural lighting conditions, the great changes in the intensity of daylight, varying as much as 1,000 foot-candles and more within a few minutes, are less trying to the eye than are the variations of relatively few foot-candles of artificial light."

The standards used in the U. S. investigation were those of the Code of Lighting School Buildings prepared jointly by the Illuminating Engineering Society and the American Institute of Architects and approved as an "American Standard" by the American Engineering Standards Committee, on which the Eye Sight Conservation Council was represented. This code makes definite provisions for natural as well as artificial lighting. (Eyesight Conservation Council of America.)

Annual Convention, White Sulphur Springs

As we go to press, the Annual Convention of the A. I. E. E. is being held at White Sulphur Springs, W. Va., June 21-25 inclusive.

The program is comprehensive of many interesting and progressive aspects of the Institute's activities furnishing many attractions for the 350 engineers in attendance.

The various committees of the Institute have surveyed the advancement of the profession in their respective fields; President Pupin, President-elect Chesney and other notable leaders have contributed addresses on the developments in electrical engineering, emphasizing the need and desirability of the electrical engineer participating both individually and collectively in national as well as local affairs. Several high-grade technical papers were scheduled for presentation, presenting gratifying advancement in the field of this specific art, as well as leading to much valuable and pertinent discussion.

The full report of the Convention will appear in the August issue of the JOURNAL.

Pacific Coast Convention to be Held in Salt Lake City, Sept. 6-10

This year the Pacific Coast Convention will be held in Salt Lake City, Utah, beginning September 6 and continuing through for four days. A number of very fine papers have been arranged for and the well-known hospitality of Salt Lake City and the points of interest in and nearby this city insure an enjoyable meeting.

The technical papers will deal with such subjects as high-voltage transmission, corona, surge recorders, stability of alternators, distribution stations, the growth of population, power-factor correction, protection of oil tanks against lightning, transcontinental telephony, carrier communication on submarine cables, electricity in lead-silver mines, safety in mine application and engineering education.

The general committee in charge of arrangements for the meeting is as follows: C. R. Higson, Chairman; P. P. Ashworth, H. G. Baker, V. L. Board, D. L. Brundige, R. J. Corfield, G. S. Covey, John Harisberger, R. A. Hopkins, C. P. Kahler, J. A. Kahn, E. A. Loew, C. A. Malinowski, J. F. Merrill, E. B. Meyer, H. T. Plumb, R. C. Powell, C. C. Pratt, Paul Ranson, L. W. Ross, John Salberg, H. H. Schoolfield, M. M. Steck, A. Vilstrup, H. B. Waters and B. C. J. Wheatlake.

A Fine Niagara Regional Meeting

A regional meeting of outstanding accomplishment was held by the Northeastern District of the Institute at Niagara Falls, N. Y., May 26-28. The meeting was notable for excellent papers, earnest discussion, well attended sessions and entertainment of high grade. About 580 attended the meeting. All sessions were held in the Niagara Hotel, the convention headquarters.

The meeting was opened on Wednesday morning, May 26, by Prof. H. B. Smith, Vice-President in the Northeastern District, after which J. A. Johnson, Chairman of the local convention committee, welcomed the assembled members in a short address. The first technical session, a symposiun on measurement of dielectric power factor, was presided over by Prof. A. E. Knowlton. Seven papers were presented which were as follows: *Phase Difference in Dielectrics*, by J. B. Whitehead; *Standards for Measuring Power Factor of Dielectrics*, by H. L. Curtis; *The Significance of Errors in Dielectric-Loss Measurements*, by C. F. Hanson; *Use of Dynamometer-Wattmeter for Measuring Dielectric Power Loss*, by E. S. Lee; *Commercial Dielectric-Loss Measurements*, by R. E. Marbury; *Three Methods of Measuring Dielectric Power Loss and Power Factor*, by E. D. Doyle and E. H. Salter and *The Dielectric-Loss-Measurement Problem* by B. W. St. Clair.

A full discussion followed to which the following contributed: P. L. Hoover, E. W. Davis, I. M. Stein, J. D. Stacy, D. DuBois, Brian O'Brien, N. L. Morgan and R. Notvest.

This symposium was continued on Wednesday afternoon with W. A. Del Mar presiding. Two papers were presented as follows: *Compensation for Errors of the Quadrant Electrometer*, by D. M. Simons and W. S. Brown; *Zero Method of Measuring Power with a Quadrant Electrometer*, by W. B. Kouwenhoven and P. L. Betz.

Discussion on these papers was given by J. B. Whitehead, H. L. Curtis, C. F. Hanson, E. S. Lee, E. H. Salter, D. M. Simons, B. W. St. Clair, W. B. Kouwenhoven, C. A. Adams and Delafield DuBois.

A delightful trip to Toronto was enjoyed by about 200 members, following the session on Wednesday afternoon. The party traveled by trolley down the Niagara Gorge to Lewiston and across Lake Ontario to Toronto on a lake steamer. At Toronto the steamer was met by the lady guests of the convention who had gone in the morning to Toronto, where they were entertained by the ladies of the Toronto Section. On the return trip across the lake dancing was enjoyed on one of the decks.

The Thursday morning technical session was opened by J. A. Johnson, the presiding officer and two papers on rectifiers were presented as follows: *Steel-Enclosed Power Rectifiers*, by O. K. Marti; *Rectifier Voltage Control*, by D. C. Prince. These papers were discussed by R. H. Wheeler, Otto Naef, F. A. Faron, D. C. Prince, E. B. Shand, and S. Q. Hayes.

E. F. W. Alexanderson next presented his paper *Polarization of Radio Waves* and this was followed by *Current Transformers*

with Nickel-Iron Cores, by Thomas Spooner. I. F. Kinnard and W. K. Dickinson discussed the latter paper.

K. B. McEachron then described informally some experimental work he has done on the calibration of Lichtenberg figures, and J. H. Cox also added some discussion on this subject. Two more papers were then presented, namely, *A Flux-Voltmeter for Magnetic Tests*, by G. Camilli, and *Circulation of Harmonics in Transformer Circuits*, by T. C. Lennox. These were discussed by R. L. Sanford, W. H. Cooney and C. H. Kline.

On Thursday afternoon inspection trips were made, the principal trip being a scenic trip in the Gorge on which stops were being made to inspect the power plants on both sides of the river.

The high point of the meeting was reached on Thursday evening in the banquet at which about 400 were present including a large number of Institute officers and other notables of the electrical profession. Vice-President H. B. Smith was toastmaster and he first introduced P. A. Schoellkopf, President of the Niagara Falls Power Company, who said a few words of welcome. He was followed in short addresses by Giuseppe Faccioli, past-vice-president in the Northeastern District, A. I. E. E.; F. L. Hutchinson, National-Secretary; H. M. Hobart, Vice-President-elect in the Northeastern District; C. C. Chesney, President-Elect of the A. I. E. E.; C. F. Scott, Past-President, and Edward D. Adams, one of the founders of the original power development at Niagara Falls.

Mr. Adams gave a most interesting account of the difficulties of starting the Niagara Falls development in 1890 and 1891. At that time, he recalled, polyphase electric power was virtually unknown in this country and the only alternating-current apparatus consisted of small single-phase belted generators. The decision to adopt alternating current was strongly opposed by such authorities as Edison and Lord Kelvin. However, it is now obvious that this decision is largely responsible for the remarkable advances made by the electric light and power industry for the success of Niagara has spread its influence over the earth. Niagara has stimulated and focussed attention on water-power development, electric transmission and the utilization of electricity. It is symbolic of engineering courage, daring and achievement.

Following Mr. Adams' address the winners of the prizes for papers presented in the Northeastern District in 1925 were announced by C. A. Stevens, secretary of the District executive committee. The prize for the "best" paper was awarded to K. B. McEachron and E. J. Wade for their paper *Study of Time Lag of the Needle Gap*. The prize for the best "first" paper was awarded jointly to C. A. Nickle and R. W. Wieseman,—their respective papers being *An Electro-Mechanical System Analyzer*, (Nickle) and *A Two-Speed Salient-Pole Synchronous Motor* (Wieseman).

The final event of the dinner was a lecture on *Modern Reproduction of Sound*, by L. T. Robinson. He talked particularly on the recording of sound on electrically cut phonograph records and reproduction by the phonograph. He illustrated his talk through the reproduction of several musical selections by means of a phonograph operating a loud speaker whose volume of sound filled the banquet room.

After the banquet a trolley trip was made to view the Falls which were being illuminated with many changing and shifting colors.

At Friday morning's session, H. C. Don Carlos in the chair, four papers were presented. The first was *Variable Armature Leakage Reactance*, by V. Karapetoff. This was discussed by P. M. Lincoln and E. B. Shand. J. A. Johnson and E. J. Burnham then presented *Fire Protection of A-C. Generators*. This was discussed by H. L. Barns, H. U. Hart, R. B. Williamson, L. W. Riggs, S. Q. Hayes, A. F. Hamdi, M. W. Smith, J. Allen Johnson, James A. Johnson and L. W. Riggs.

F. V. Smith then presented his paper *Automatic and Supervisory Control of Hydroelectric Stations* and this was discussed by W. H. Gerrie, C. F. Publow and A. G. Darling.

The paper *Retardation Method of Loss Determination as Applied to the Niagara Falls Generators* by J. A. Johnson was then presented. Those discussing it were R. B. Williamson, E. M. Wood, V. Karapetoff, O. K. Marti and W. J. Foster.

Friday afternoon's session on power transmission was presided over by P. H. Thomas. S. Q. Hayes first presented a lecture illustrated with slides on *Interconnection and Superpower*. Mr. Hayes showed the large interconnected systems in this and other countries. L. E. Imlay then presented a paper on *European Transmission Practises* by G. F. Chellis. Following this three more papers were presented, namely, *Lightning and Other Experience on 132-kv. Transmission Lines*, by M. L. Sindeband and P. S. Sporn; *Notes on the Vibration of Transmission-Line Conductors*, by Theodore Varney; *Transmission-Line Sag Calculations, by H. B. Dwight.* Extended discussion followed by F. W. Peek, L. E. Imlay, L. C. Nicholson, E. S. Healy, S. S. Hertz, M. G. Lloyd, H. B. Vincent, A. E. Knowlton, N. J. Neall, C. F. Scott, A. O. Austin, J. H. Cox, V. Karapetoff, and H. Halperin.

On Friday evening there were two interesting features. The first was a piano recital by Professor Vladimir Karapetoff who chose for his subject Wagner's opera Parsifal. Prof. Karapetoff made the rendition of the music especially attractive by a previous explanation of the story of the opera, by lantern slides showing principal events and by explanatory verbal interpolations.

The meeting ended with a lecture by G. S. Anderson on the *Present and Future Development of Niagara Falls* which was illustrated with beautiful motion pictures.

This, the third regional meeting held by the Northeastern District, was in all ways a success, and the committees in charge deserve the highest commendation for the organization of the meeting and the smoothness with which all the events were conducted.

Institute Award of Prizes

The Committee on Award of Institute Prizes, composed of Messrs. E. B. Meyer, Chairman of the Meetings and Papers Committee, L. F. Morehouse, Chairman of the Publication Committee and Percy H. Thomas, Chairman of the Power Transmission and Distribution Committee, reported on the date of June 15, as follows:

"The Committee on Award of Institute Prizes has carefully considered the various papers submitted during the year 1925. They are all of a high calibre and show care in their preparation, and thoroughness of the work done. Some cover highly technical research work, important in a particular field of electrical progress, while others are of somewhat more general interest. All contribute information of value and it has been a matter of considerable difficulty to determine the prize paper in both of the groups.

"After careful deliberation we have selected the following:

First Paper Prize for the Year 1925

A Two-Speed Salient-Pole Synchronous Motor, by R. W. Wieseman (Published in April 1925)

Honorable Mention is awarded to

Effect of Repeated Voltage Application on Fibrous Insulation, by F. M. Clark (Published in January 1925)

Overvoltages on Transmission Systems Due to Dropping of Load, by E. J. Burnham (Published in June 1925)

"In reviewing the papers coming under the transmission group, it also was extremely difficult owing to the general excellence of the papers offered, to select one which might be considered to surpass the rest. The Committee, however, has agreed on the following:

Transmission Prize

The Klydonograph and Its Application to Surge Investigation, by J. H. Cox and J. W. Legg, (Published in October 1925 issue of the JOURNAL)

Honorable Mention is awarded to

Power System Transients, by V. Bush and R. D. Booth, (Published in March 1925 issue of the JOURNAL)

Fundamental Considerations of Power Limits of Transmission Systems, by R. E. Doherty and H. H. Dewey, (Published in October 1925 issue of the JOURNAL)."

Arrangements were made for the presentation of these prizes at the Annual Convention of the Institute, White Sulphur Springs, West Virginia, on Tuesday morning, June 22.

Revised Report on Standards for Electrical Measuring Instruments Available

A completely revised report on A. I. E. E. Standards for Electrical Measuring Instruments (Section 33 of the Revised Standards) is now available, without charge, for distribution to all those interested in the subject, members or non-members.

This report is issued for purposes of criticism and revision before final adoption as an A. I. E. E. Standards. The Standards Committee will greatly appreciate any suggestions based upon the application of the proposed Standards to general practise. All communications should be addressed to H. E. Farrer, Secretary A. I. E. E. Standards Committee, 33 West 39th St., New York, N. Y.

National Exposition of Power and Mechanical Engineering

Preliminary plans for the Fifth National Exposition of Power and Mechanical Engineering interests indicate that the coming event which is to be held at Grand Central Palace, New York City, December 6-11 inclusive, will be larger and more comprehensive than any of their previous Expositions. Approximately 140 exhibitors have arranged displays in the heating and ventilating field, some 75 in machinery and considerable space will be devoted to exhibits on power generating equipment. In all, the exhibitors will total over 400. Mr. I. E. Moultrop of the Edison Illuminating Co. of Boston is chairman of the Advisory Board and the managers of the Exposition are Charles F. Roth and Fred W. Payne, International Exposition Company, Grand Central Station, to whom all inquiries should be addressed.

New York Electrical Society Develops a Neglected Field

ELECTS OFFICERS FOR 1926-27

At the annual meeting of the New York Electrical Society held on the afternoon of June 14, 1926 at Institute headquarters, 33 West 39th Street, the retiring President of the Society, H. A. Kidder, Superintendent of Motor Power, Interborough Rapid Transit Company, called attention to the much broadened aim and scope of the New York Electrical Society as instanced in its work during the past year. He outlined the new policy, as follows: "To interpret to thinking people the newest things in discovery and science; to present in its meetings the latest achievements in the art and in industry; to acquaint the public with the proper status of teachers, scientific workers and engineers, and with the social value of their work." The determined attempt to shape the work of the Society in the direction indicated has been marked with rapid and increasing success. Attendance at meetings has jumped to an average of approximately 850. Through popularization, the meetings have evidently gained greatly in favor with those within the industry. It is felt that such work as the New York Electrical Society is trying to do, should be done nationally, for if accomplished it would constitute an important and valuable public service. The better people understand the nature of scientific and industrial research and the nature and social value of the work of the engineer, the greater will be the resources at the command of such workers.

The plans for the fall meetings are still tentative. One of particular interest, which is sure to be held, will be a demonstration of "Synchronized Talking Motion Pictures and Music" with popularized explanation of the process of development and operation.

The following officers were elected for the administrative year 1926-27: President, S. P. Grace, Commercial Development Engineer, Bell Telephone Laboratories, Inc.; Vice-Presidents; E. E. Dorting; Lighting Engineer, Interborough Rapid Transit Co.; Dr. E. E. Free, Consulting Engineer, J. P. Alexander, Sales Engineer, General Electric Co.; Treasurer, David Darlington, Assistant Treasurer, New York Edison Co.; Secretary, H. E. Farrer.

Automotive Engineers to Discuss Aircraft Progress

Three technical sessions, an inspection trip to the Naval Aircraft Factory and an Aeronautic Banquet will be the attractions at the annual aeronautic meeting of the Society of Automotive Engineers, to be held in Philadelphia on September 2 and 3 at the Bellevue-Stratford hotel. This meeting immediately precedes the National air races to be run in Philadelphia consecutively from September 4 to 11.

In view of the great amount of night flying that is now being done and that will increase greatly in the future, a joint address on equipment and methods for illumination of air routes, to be presented at the same session by C. T. Ludington, of the B B T Corporation, and H. C. Ritchie, of the General Electric Co., will be of much interest.

Direction finding by radio in an airplane is a recent development of prime importance, particularly when the landscape is obscured by darkness, fog or storms. The remarkable advancement that has been made in the practical application of directional radio to air transport will be described by Lieut. L. M. Wolfe and Capt. W. H. Murphy, of the Air Service radio laboratory at McCook Field, Dayton, O.

National Research Council

Doctor Charles M. Upham Receives New Appointment

The engineering world will be interested in the announcement that Charles M. Upham, who, for five years was North Carolina's Chief Highway Engineer, has tendered his resignation effective June 1st, and will shoulder the duties of Managing Director of the American Road Builders' Association, and in addition, accept a few connections as consulting engineer, among them, the reorganization of the construction division of the Mexican Federal Highway Commission, he already having reorganized the engineering section.

Doctor Upham received two degrees from Tufts College and a third from the North Carolina State University. He is Director of the Highway Research Board of the National Research Council, Vice-President of the National Traffic Association, President of the North Carolina Society of Civil Engineers, Member of Concrete Institute, Permanent International Association, of Road Congresses and other engineering and highway organizations.

The John Ericsson Medal Award

The first award of the John Ericsson gold medal was made to Doctor Svante Arrhenius on the evening of May 29th at the Hotel Willard, Washington, D. C. This was following the unveiling of the memorial Ericsson Statue on the Mall at which the Swedish Crown Prince, Princess Louise, President Coolidge were present, besides many other distinguished international figures.

Graduate Instruction in the Moore School

Beginning with the academic year 1926-27, graduate instruction will be offered in the Moore School of Electrical Engineering, with the degree of Master of Science in Electrical Engineering.

A prescribed course will be offered, the purpose of which is to prepare young men for engineering research or for teaching. The course includes the following subjects: Introduction to Mathematical Physics, Advanced Mathematics for Engineers, Advanced Electric Circuit Theory, Electron Theory and its Engineering Applications, and a Thesis.

To be admitted to this graduate course, the applicant must have completed with credit an undergraduate course in Electrical Engineering substantially equivalent to that given in the Moore School.

In order to encourage students who are properly qualified to add a fifth year to their University training, four graduate fellowships are offered. Each fellowship carries free tuition and a cash stipend of $500, payable in equal installments, October 1 and February 1. Applications for these fellowships should be addressed to the Dean, Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa.

PERSONAL MENTION

THOS. W. WOOTTON has resigned from the Adirondack Power and Light Corporation of Schenectady, N. Y., and is now located in the engineering department of the Duquesne Light Company, Pittsburgh, Pa.

R. L. MCLELLAN, managing director of the Cia Westinghouse Electric Internacional, S. A., of Argentine, has recently been elected president of the United States Chamber of Commerce in Argentine.

W. R. WHITNEY, director of the research laboratory, and E. F. W. Alexanderson, consulting engineer who gained international fame with his radio inventions and developments, were awarded the honorary degree of doctor of science on Monday, June 14, Dr. Whitney at Syracuse University and Mr. Alexanderson at Union College.

ANSON W. BURCHARD, chairman of the board of directors of the International General Electric Company and vice-chairman of the General Electric Company, recently received the degree of doctor of laws from Union College.

W. J. FOSTER, consulting engineer of the General Electric Company, had the honorary degree of doctor of science conferred upon him by Williams College at its commencement exercises on Monday, June 21. Mr. Foster, an alumnus of Williams College, took graduate work at both Williams and Cornell. With the General Electric Company he has specialized in alternating-current apparatus design.

HOMER CLYDE SNOOK, a fellow of the Institute, has just received the degree of Doctor of Science from Ohio Wesleyan University. Doctor Snooks has been referred to as "originator of many fundamental patents in X-ray and wireless inventions; organizer of electrical manufacturing companies; holder of the Edwards Longstreth Medal of the Franklin Institute; staff engineer, Bell Telephone Laboratories, New York; gifted with insight and technical proficiency to have rendered in scientific fields a service of high order."

Obituary

Rudolf Schmolck, who was enrolled as an Associate of the Institute during the year 1925, died May 5, 1926, in Chicago. Mr. Schmolck was born in Germany in 1892, and was educated at the University of Heidelberg and the University of Berlin. Since December 1923 he had been employed by the Automatic Electric Co. of Chicago as a research engineer.

Olin J. Emmons died at his home in Elgin, Illinios, on the 9th of May. For ten years he had been an Associate of the Institute. Mr. Emmons received his electrical education at the University of Iowa, where he took the B. S. degree in 1907 and the E. E. in 1914. At the time of his death he was a wire chief at the Chicago Telephone Co.

Benjamin T. Viall, chief electrician for the Sunnyside Mining and Milling Co. at Eureka, Colorado, died at Silverton, Colorado, Feb. 3, 1926. Mr. Viall was born in 1873, and was graduated from Leland Stanford University in 1900. After three years spent with the General Electric Co. and the Edison Electric Co. he went with the Los Angeles Traction Co. in 1903. The same year he became an Associate of the Institute.

Charles W. Schaifer died in Schenectady, N. Y., on the 4th of April. For eleven years he had been in charge of the section handling "Special Testing of Electrical Machinery and Devices" in the General Engineering Laboratory of the General Electric Co. Mr. Shaifer was a graduate of the Agricultural and Mechanical College of Missippi of the class of 1912, and an Associate of the Institute since 1925.

Charles Griffith Young, Fellow of the Institute, died suddenly in Porto Rico, June 16, while there on a professional engagement. Mr. Young was born at Bath, Steuben County, New York, November 1, 1866. He attended the Haverling Academy there, taking special courses on technical subjects under private tutelage. His first work in the field was with the Schuyler Electric Company, of Hartford and Middletown, Conn., with whom he took an expert course in their every deparment during a two years' period. In 1887 he became general superintendent and electrician for the Mount Morris Electric Light Company, New York City, remaining with them until 1892, when he was chosen construction manager for the White-Crosby Company and the J. G. White Engineering Co., with foreign and domestic practise. Under his direction and operation of public utilities and construction engineering, over 2000 miles of electric railways were built in this and other countries. Mr. Young specialized upon investigations of professional undertakings, both proposed and actual, ultimately leading into the development of his own company, The C. G. Young Co., Inc., of which he was president. His engineering work extended over a wide range,—Canada, South America, Central America, China, Japan, and the Phillippines, New Zealand, Australia, Siberia and several of the European countries. He joined the Institute as an Associate in 1889, but in 1913 was transferred to the grade of Fellow. He was a respected and active member of the National Electric Light Association, the New York Electrical Society, the American Electric Railway Transportation and Traffic Association, the American Electric Railway Engineering Association, Associate Member of the American Society of Civil Engineers, member of the Pan American Society, the Pan American Chamber of Commerce, the Steuben Society, beside belonging to the Engineers' Club, the Railway Club, the Indian House Club and the Circumnavigators. He was the author of a paper of technical worth entitled, "Logical Basis for Valuations." This, besides being reprinted in separate pamphlet form, was published in the *Electric Traction* weekly of Jan. 21, 1911. Mr. Young had been three times around the world.

A. R. Rivet, an Associate of the Institute since 1903, died the 23rd of May in St. Louis, Mo. He was a former editor of the *Electrical Era*, a monthly published in that city, and at the time of his death was financial and commercial editor of the *St. Louis Globe-Democrat.* Mr. Rivet had had much practical electrical experience. He was born at Florissant, Mo., and for over a year was connected with the Municipal Electric Lighting Co. there, having charge of the contracting and estimating of cost of erection of Commerical Arc Lamps. He also was in charge of the motor department of the General Electric Co. in that city for about a year. For several years, he served as expert in the purchase of electrical machinery for isolated plants and was considered a valuable authority by all employing

his services. Mr. Rivet was an inveterate student and in his personal library he had all volums of the *Electrical World* for 15 years back and the *Street Railway Journal* for ten years.

George D. Shepardson, member of the Institute and head of the Electrical Engineering Dept. of the University of Minnesota died at Florence, Italy, of pneumonia, May 26. He left last spring for a trip around the world on a sabbatical leave of absence until next September.

Prof. Shepardson was born November 20, 1864 at Cincinnati Ohio. He attended the Granville Ohio High School and graduated from Denison University 1885 A. B. and A. M. 1888, specializing in Latin, Greek, German and French. He received his degree of Mechanical Engineer from Cornell in 1889. During his other sabbatical year in 1912, he received a degree of Doctor of Science from Harvard. One of his hobbies was the collectiong of old forms of lighting devices. While on his trip he had already gathered a number of primitive and ancient lamps of various designs for the museum of the Electrical Engineering Department of the University. These are now lying in bond in Minneapolis.

Prof. Shepardson has taught at the Young Ladies Institute at Granville, Ohio, Cornell University and since 1891 until his death has been Head of the Department of Electrical Engineering at the University of Minnesota. During the period of his professorship at the University of Minnesota the department has grown from almost nothing to a point where it is the largest in the College of Engineering, graduating 80 senior electrical engineers this spring and now housed in a new building costing $375,000.

Prof. Shepardson was a very prolific writer, having published more than 125 technical articles, in addition to several books, one of the latter "Elements of Electrical Engineering" for now being used in several colleges as a textbook for s phomore electrical engineers.

He was a member of a number of technical societies, among them the Society for the Promotion of Engineering Education, American Association for the Advancement of Science.

John J. Flather, head of the Department of Mechanical Engineering at the University of Minnesota and Associate of the Institute, died suddenly on May 14th at his home in Minneapolis.

Professor Flather was born at Philadelphia, June 9, 1862. He was educated in private schools in Scotland, at the High School in Bridgeport, Conn., and at the Sheffield Scientific School, Yale University, from which he was graduated in 1883. He took graduate studies at Yale, Cornell and the University of Edinburgh, receiving his Ph. B. from Yale in 1885 and his M. M. E. from Cornell in 1890. His early practical experience covered a full machinist's apprenticeship in various New England shops, including Flather & Co., Nashua, N. H.; he served also as foreman at the Ansonia Electric Supply Co. and as superintendent for the Hotchkiss Mfg. Co. In 1888 he became instructor in Mechanical Engineering at Lehigh University, remaining there for three years, followed by seven years at Purdue University. In 1898 he became Professor of Mechanical Engineering at the University of Minnesota, where he remained until the time of his death. He was a prolific writer, and his consulting work covered some import engineering projects of the Northwest, including municipal water works, electric light plants, factories and power plants. He entered the research field in 1888 investigating gas and combustion performances with natural gas, artificial gas, gasoline and kerosene power for machinery drive; also locomotive tests, train resistance tests, rope, belt and gear drive, refrigeration and many other fields of engineering interest. He joined the Institute in 1892 and was also a member of the Society of Industrial Engineers, the American Association of University Professors, the Minneapolis Engineers' Club, the Newcomen Society of London, the Authors' Club and the honorary societies of Sigma Xi, Tau Beta Pi and Pi Tau Sigma. He was secretary and vice-president of Section D of the American Association for the Advancement of Science and served as treasurer and vice-president to the Society for the Promotion of Engineering Education.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

1.—J. Roy Barclay, 3424 Harrison, Kansas City, Mo.
2.—I. V. Beall, Wright Hotel, 4th & Hinkson Sts., Chester, Pa.
3.—Reynolds Bellows, 28 East 39th St., New York, N. Y.
4.—William A. R. Brown, c/o Radio Corp. of America, 33 West 42nd St., New York, N. Y.
5.—Aleck. Burk, c/o Lempert, 1327 Wilkins Ave., New York N. Y.
6.—J. F. Clinton, 3682 Broadway, New York, N. Y.
7.—A. G. Corbin, 753 Crescent Ave., Buffalo, N. Y.
8.—Hugh Denehy, The Inst. of Elect. Engrs., Savoy Pl., Victoria Embankment, London W. C. 2, Eng.
9.—John P. Flood, 414 No. Iowa Ave., Eagle Grove, Iowa.
10.—John Fowler, 25 Bettswood Rd., Norwalk, Conn.
11.—Clyde D. Grim, 623 Chestnut St., Reading, Pa.
12.—Frank I. Grover, 1831 E. 82nd St., Terrace, Kansas City, Mo.
13.—Stephan G. Guth, 419 Hampton Ave., Wilkinsburg, Pa.
14.—A. R. Henry, 633 Coristine Bldg., 20 St. Nicholas St., Montreal, Que, Can.
15.—William A. Hiney, Colonial Apts., Media, Pa.
16.—J. W. Hopkins, 136 E. 3rd St., Keyport, N. J.
17.—Niels K. Knudsen, N. Y. Edison Co., 44 E. 23rd St., New York, N. Y.
18.—Alexander Knut, 11th Ave. & 17th St., New York, N. Y.
19.—F. A. Lindlof. 610 So. Spring St., Los Angeles, Calif.
20.—Charles Wm. Lucck, 1454 First Ave., New York, N. Y.
21.—Shu-Sing Man, 541 West 124th St., New York, N. Y.
22.—Irving Menschik, 48 W. 4th St., New York, N. Y.
23.—Arthur R. Michaelson, Mezzine Dv., Cresskill, N. J.
24.—Erwin H. Mitchell, 481 6th St., Brooklyn, N. Y.
25.—Daniel T. Morgan, Power, W. Va.
26.—Jose P. Ortiz, 23rd St. & 4th Ave., New York, N. Y.
27.—Olof E. Permanson, 44 E. 23rd St., New York, N. Y.
28.—J. C. Peterson, 5125 Kimbark Ave., Chicago, Ill.
29.—Chester A. Raymond, 131 W. 17th St., Erie, Pa.
30.—Irving T. Roberts, 2355 Prairie Ave., Evanston, Ill.
31.—Wm. D. Robinson, Sterro-Woolley, Wash.
32.—Carl Russell, Albers Apt. G., Chehalis, Wash.
33.—W. J. Strieby, 104 Broad St., New York, N. Y.
34.—Herbert S. Summers, Standard Oil Co., of N. Y., Sofia, Bulgaria.
35.—O. G. Utt, 4738 Oak St., Kansas City, Mo.
36.—Albert C. Weyandt, 1200½ Negley St., Farrell, Pa.
37.—C. A. Winder, Southern Equipment Co., San Antonio, Tex.
38.—Flavel M. Williams, 106 So. Elliott St., Brooklyn, N. Y.
39.—Fred Willoughby, Jr., 500 West 111th St., New York, N. Y.
40.—W. H. Wilson, 13 Westminster Ave., East Park Hull, England.
41.—W. G. Withington, Commercial Nat'l Bank Bldg., Washington, D. C.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES MAY 1-31, 1926

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

ALTERNATING CURRENTS.

By Carl Edward Magnusson. 3rd edition. N. Y., McGraw-Hill Book Co., 1926. 611 pp., illus., diagrs., tables, 9 x 6 in., cloth. $5.00.

A textbook based on the course given in the University of Washington. The aim has been to aid the student to gain clear concepts of what takes place in alternating-current machinery, to explain the relations between the factors involved and to explain the physical facts in mathematical forms in such a manner that the student shall understand the equations and be able to use them in the solution of industrial problems. The new edition has been thoroughly revised.

AUS DEM REICH DER TECHNIK.

By Max Maria von Weber. Berlin, V. D. I. Verlag, 1926. 188 pp., port., 8 x 6 in., cloth. 7,-r. m.

This collection of stories, long out of print, is now reissued by the press of the Verein deutscher Ingenieure. Weber was born in 1822 and died in 1881. He was educated as an engineer and spent his life in railroad service in Germany and Austria. He is best known, however, for his stories, which unite technical knowledge and poetic ability in an unusual degree. Those here reproduced are based on various incidents of railroad operation. Through them all runs a desire to arouse pride in his vocation in the railroad employer and to show the public the importance to national prosperity of the engineer and the mechanic.

AUSSENDUNG UND EMPFANG ELEKTRISCHER WELLEN.

By Reinhold Rüdenberg. Berlin, Julius Springer, 1926. 67 pp., diagrs., 9 x 6 in., paper. 3,90 r. m.

There are many books on the action of radio sending and receiving mechanisms, but there is not a great deal available on the mechanism of the wave passage from sender to receiver. In this little book the interaction between the currents and voltages in the stations and the electromagnetic waves flowing between them is considered, together with the problem of wave propagation in the intervening medium. The discussion is confined to undamped waves.

CORROSION; CAUSES AND PREVENTION.

By Frank N. Speller. N. Y., McGraw-Hill Book Co., 1926. 621 pp., illus., diagrs., tables, 9 x 6 in., cloth. $6.00.

An important reference work for all who are interested in any of the many phases of the problem of corrosion, combined with a handbook of practical preventive methods of interest to engineers and architects.

Part one treats of general principles. After an explanation of the nature and mechanism of corrosion and of the theories advanced to explain it, the author discusses the influence of methods of manufacture and treatment, of composition and of external factors on corrosion. The principles and methods of testing are then described and a chapter is devoted to the question of the relative corrodability of the various ferrous metals.

Part two discusses measure for preventing corrosion under various service conditions. Corrosion in the air, under water or under ground, corrosion in hot water systems and in steam plants and corrosion caused by chemicals or electric currents are discussed at length. Many references to other work are given in the notes and bibliography.

Dr. Speller's long study of the subject has enabled him to write a book of great value to all engineers.

DIE DRAHTSEILBAHNEN.

By P. Stephan. 4th edition. Berlin, Julius Springer, 1926. 572 pp., illus., plates, 9 x 6 in., cloth. 33,-m. k.

A detailed descriptive work on aerial ropeways and cableways, and telphers. The book is written from the point of view of the user rather than the manufacturer.

After a brief historical introduction, the various elements of ropeways (cables, supports, cars, stations, safety devices, etc.) are described. Examples of the use of ropeways as mountain railways and industrial conveyors, in mines, harbors and mills are then given, after which special types, such as gravity ropeways, single-cable ways, passenger ropeways and cableways are discussed. Economic and legal matters are then taken up, followed by a chapter on erection and operation. The types described are those now manufactured in Germany.

ETHICS OF BUSINESS.

By Edgar L. Heermance. N. Y., Harper & Bros., 1926. 244 pp., 8 x 6 in., cloth. $2.00.

Standards of business conduct, sometimes unwritten, sometimes expressed in definite codes, have been developing during the past quarter-century until today, Mr. Heermance believes, the average American merchant of the better class is probably more ethical than his patrons. In this book he presents these standards and the reasons for them, giving a useful picture of the development of business ethics in the United States. The author also intends his book as an introduction to social ethics, and therefore makes certain generalizations and interpretations of the ethical process in trade associations, as a contribution to ethical theory.

INDUSTRIAL STOICHIOMETRY.

By Warren K. Lewis and Arthur H. Radasch. N. Y., McGraw-Hill Book Co., 1926. (Chemical Engineering Series). 174 pp., diagrs., tables, 9 x 6 in., cloth. $2.50.

While the chemist is always taught the use of stoichiometric methods of computing quantitative analyses, he frequently is not trained to use them in industrial work. This textbook is designed to familiarize the beginner with correct methods for the quantitative interpretation of data in industrial work by a detailed presentation of typical cases of industrial processes, such as the operation of gas producers, lime burning, kiln and furnace design, plant design, sulfur burning, and iron smelting.

INSULATED ELECTRIC CABLES, v. 1; Materials and Design.

By C. J. Beaver. N. Y., D. Van Nostrand, 1926. 264 pp., illus., diagrs., tables, 10 x 7 in., cloth. $11.00.

Intended to supplement recent publications about insulated cables, which are chiefly devoted to their electrical properties, by a statement of the principles that underlie their design and manufacture. These, the author says, have not been comprehensively treated in any previous work.

The present half of the work discusses the materials—metals, insulants and protective substances—, the design of conductors,

the design and properties of dielectrics, and the factors in voltage rating. The second volume will treat of manufacture and installation.

JAHRBUCH DER ELEKTROTECHNIK . . . . 1924.

Edited by Karl Strecker. Mün. u. Ber., R. Oldenbourg, 1926. 269 pp., 10 x 7 in., paper. 14,20 mk.; bound, 15,40 mk.

A digest of over five thousand articles on electrical engineering which were published in some two hundred periodicals during 1924. The digests are the work of specialists and give a valuable summary of advances in each line, conveniently arranged for reference use. Machine design, power transmission and distribution, power plants, lighting, railroads, electric driving and other industrial uses of electricity, primary and secondary batteries, electrochemistry and electrometallurgy, telegraphy, telephony, signaling, electrical measurements and scientific investigations are included in the book. References are given to the original papers and author and subject indexes are supplied.

NEW VIEW OF SURFACE FORCES; A COLLECTION OF THE SCIENTIFIC PAPERS OF WILSON TAYLOR. Toronto, Univ. of Toronto Press, 1925. 240 pp., illus., diagrs., tables, 9 x 6 in., cloth. A Memorial Volume. Price not quoted.

When the author died, in 1923, after four years of research in physics, he left a number of papers, chiefly upon surface tension and molecular physics. Those here printed discuss the coalescence of liquid spheres and the law governing it, cohesion and adhesion in liquids and solids, the potential energy of free molecules, etc. One paper is devoted to flotation oils and their mode of action.

DE ONTWIKKELING VAN DE ELECTRICITEITSVOORZIENING VAN NEDERLAND. 1925.

By Vereeniging van Directeuren van Electriciteitsbedrijven in Nederland. Amsterdam, P. N. Van Kampen & Zoon, 1926. 568 pp., illus., maps, 11 x 9 in., cloth. 25 guilders. (This volume can be supplied by the Central Bureau of the Association, Maastricht, Breedestraat 11, at the price quoted).

In commemoration of its tenth anniversary, the Association of Managers of Electricity Supply Works in the Netherlands has issued this handsome volume. It contains elaborately illustrated accounts of the service provided by the utilities controlled by members of the Association, which furnish practically the entire electrical supply of the country. In addition to descriptions of equipment, service, etc., detailed statistics and maps are included, so that the book is a complete presentation of the development of electricity supply in the Netherlands.

RAILWAY ENGINEERING AND MAINTENANCE CYCLOPEDIA. 2nd edition, 1926, [of Maintenance of Way Cyclopedia]. N. Y., Simmons-Boardman Publ. Co., 1926. 1072 pp., illus., 12 x 9 in., cloth. $8.00.

The Cyclopedia is a convenient, authoritative assemblage of information on current practise in the engineering and maintenance of railroad track, bridges, buildings, water service and signals. This information is arranged in sections, each of which discusses the work of one of these branches. A general section cares for matters of interest to all. A dictionary of terms gives convenient definitions and serves as an index. Condensed catalogs of manufacturers are included. The sections were edited by a number of specialists actively engaged in railroading.

S. A. E. HANDBOOK, March 1926. N. Y., Society of Automotive Engineers, 1926. Various paging, diagrs., tables, 7 x 4 in., fabrikoid. $2.50 to members. $5.00 to non-members.

The standards and recommended practises of the Society of Automotive Engineers, some six hundred in number, have been revised and published in a bound volume of convenient pocket size, replacing the former data sheets supplied to its members. The contents are divided into sections relating to the power, plant, lighting, electrical equipment, parts and fittings, materials, transmission, axles and wheels, tires, frames, etc. Revisions are to appear twice each year hereafter.

TECHNISCHES WORTERBUCH . . . . DES MASCHINEN-UND SCHIFFBAUES, v. 2; Englisch-Deutsch.

By Erich Krebs. 2nd edition. Ber. u. Lpz., Walter de Gruyter & Co., 1926. 163 pp., 6 x 4 in., cloth. 1,50 r. m.

A convenient English-German pocket dictionary of technical terms used in mechanical engineering and naval architecture. Apparently includes all the principal terms, with satisfactory equivalents, and is remarkably cheap.

LA TELEPHONE AUTOMATIQUE.

By H. Milon. Paris, Gauthier-Villars et cie, 1926. 414 pp., illus., plates, 10 x 7 in., paper. 90 fr.

A concise textbook on automatic telephony, prepared especially for French students. The author omits any history of the development of the apparatus and confines himself, after giving an outline of the essential characteristics of the different systems, to a detailed account only of those in use in France. These include the Automatic Electric, the Thomson-Houston, the Siemens and Halske, the Western Electric and several semi-automatic systems. Data for the design of installations are given.

THEORY AND PRACTISE OF ALTERNATING CURRENTS.

By A. T. Dover. Lond. & N. Y., Isaac Pitman & Sons, 1926. 539 pp., illus., diagrs., 9 x 6 in., cloth. $5.00.

Devoted to general principles, circuits, polyphase systems, non-sinusoidal wave-forms, the magnetization of iron, instruments, measurements, and an elementary treatment of the initial conditions in the simpler electric circuits. Intended for use as a college text, introductory to the study of alternating-current machines and apparatus, it treats these principles on a broader basis than some textbooks do. Among the special features are an extended application of the circle diagram to series, parallel series-parallel circuits; the reduction of the general circuit to its equivalent series-parallel form and the development of a load diagram therefor; the calculation of currents in unbalanced polyphase circuits; and the theory of the principal types of measuring instruments.

Past Section and Branch Meetings

SECTION MEETINGS

Atlanta

Developments of the Columbus Electric and Power Company, by R. M. Harding. November 6. Attendance 60.

The Traffic Problem in Atlanta, by P. S. Arkwright, Georgia Railway and Power Co. January 18. Attendance 10.

Recent Developments in the Manufacture of Chemical Fiber, by F. H. Griffith, The Viscose Co., and

Cellucose, by R. C. Dort, the American Cellucose and Chemical Co. March 18. Attendance 27.

Ceramics, by A. V. Henry, Georgia School of Technology. April 22. Attendance 17.

Baltimore

Radio Broadcasting Station, Consolidated Gas and Electric Company, by F. A. Fallon, and

Radio Equipment, by P. M. Rainey, Graybar Electric Co. January 15. Attendance 65.

Mercury-Arc Rectifier as Applied to Power Development, by H. D. Brown, General Electric Co. Illustrated with slides. February 19. Attendance 90.

Mechanical Power and Trend of Civilization, by C. E. Skinner, Westinghouse Electric and Mfg. Co. March 19. Attendance 110.

Automatic Testing of Watt Hour Meters, by J. S. Cruickshank, Consolidated Gas, Electric Light and Power Co., and

Maintenance and Care of Storage Batteries, by A. Albaugh and F. Fried, Consolidated Gas, Electric Light and Power Co. April 16. Attendance 87.

Annual Banquet. Joint with A. S. M. E. April 29. Attendance 156.

Boston

Business Meeting. Election of Officers. Banquet preceded the meeting. May 18. Attendance 238.

Cincinnati

Research, by Dean Herman Schneider, University of Cincinnati. Illustrated with slides. May 20. Attendance 216.

Cleveland

Mental Attitude, by Dr. M. I. Pupin,, National President, A. I. E. E. May 18. Attendance 100.

Connecticut

Fatigue Prevention is Accident Prevention, by Dr. H. W. Haggard, Yale University. The following officers were elected: Chairman: A. E. Knowlton; Secretary-Treasurer, R. G. Warner. May 19. Attendance 40.

Denver

The Changing Status of the Engineer, by Dr. F. B. Jewett, American Telephone and Telegraph Co. The following officers were elected: Chairman, W. H. Edmunds; Vice-Chairman, A. L. Jones; Secretary-Treasurer, R. B. Bonney. May 28. Attendance 500.

Erie

Talk by Giuseppe Faccioli, General Electric Co., on a trip through Europe in a machine, with special reference to engineering conditions. The following officers were elected: Chairman, F. A. Tennant; Secretary, L. H. Curtis. May 25. Attendance 94.

Ithaca

The Social and Economic Aspects of Niagara Falls, by W. K. Bradbury, Niagara Falls Power Co. Illustrated with slides and motion pictures. A dinner preceded the meeting. May 7. Attendance 125.

Lehigh Valley

Oil Switches, by Wm. S. Edsall, Condit Electric Mfg. Co., and

Application of the Electric Motor to Steel Mills, by G. E. Stoltz, Westinghouse Electric and Mfg. Co. A dinner preceded the meeting. April 23. Attendance 135.

Lynn

Street and Highway Safety, addresses by Dr. George W. Haywood, President of Lynn City Council; Hon. Ralph S. Bauer, Mayor of Lynn; Deputy-Commissioner Good of Boston; C. A. B. Halvorson, General Electric Company, and S. C. Rogers, Street-Lighting Department, Lynn. June 3. Attendance 150.

Madison

A talk was given by D. W. Mead, University of Wisconsin, on some of his experiences in building hydro-electric plants. The following officers were elected: Chairman, E. J. Kallevang; Secretary, H. J. Hunt. May 26. Attendance 24.

Milwaukee

The Inadequacy of American Patent and Trade-Mark Protection, by R. S. Hoar, The Bucyrus Co. May 19. Attendance 100.

Minnesota

Dinner Dance. May 11. Attendance 61.

Nebraska

Long Distance Telephone Transmission—Fifty Years of Progress, by A. F. Rose, American Telephone and Telegraph Co. Demonstrated. May 12. Attendance 85.

Pittsfield

Street and Highway Safety—addresses by W. A. Whittlesey, engineer of the Pittsfield Electric Co., and Chief of Police John L. Sullivan. May 27. Attendance 150.

Portland

Manual, Supervisory and Automatic Control, by Albert Kalin, Westinghouse Electric and Mfg. Co. A motion picture, entitled "From Mine to Consumer," was shown. May 12. Attendance 85.

Rochester

A motion picture, entitled "The Yoke of the Past," was shown. The following officers were elected: Chairman, E. C. Karker; Vice-Chairman, R. G. Thompson; Secretary-Treasurer, J. R. Clark. May 7. Attendance 40.

San Francisco

Elements of Transmission-Line Stability Problems, by A. W. Copley, Westinghouse Elec. & Mfg. Co., and Roy Wilkins, Pacific Gas and Elec. Co. A dinner preceded the meeting. May 28. Attendance 80.

Supervisory Systems for Control and Indication, by C. E. Stewart. Illustrated with motion pictures and slides. June 3. Attendance 58.

Sharon

Mechanical Power and the Trend of Civilization, by C. E. Skinner, Westinghouse Electric and Mfg. Co. The following officers were elected: Chairman, H. L. Cole; Secretary-Treasurer, L. H. Hill. June 1. Attendance 75.

Springfield

Electric Time Equipment, by G. F. Harter, The Standard Electric Time Co. May 24. Attendance 45.

Syracuse

Radio and Interference, by E. P. Peck, Utica Gas and Electric Co. March 8. Attendance 175.

Developments in Radio Wave Propagation, by E. F. W. Alexanderson, Radio Corporation of America. March 29. Attendance 225.

Engineering Mechanics at the Bureau of Standards, by L. B. Tuckerman. April 12. Attendance 195.

Toledo

Inspection trip to the Toledo Furnace Company. May 19. Attendance 32.

Urbana

Business Meeting. The following officers were elected: Chairman, J. T. Tykociner; Secretary-Treasurer, L. B. Archer. May 12. Attendance 12.

Utah

New Electrical Developments, by A. L. Jones, General Electric Co. Illustrated with slides. May 26. Attendance 40.

Vancouver

Annual Meeting. The following officers were elected: Chairman, R. L. Hall; Secretary, C. W. Colvin. June 1. Attendance 46.

BRANCH MEETINGS

Alabama Polytechnic Institute

The Oscillograph, by Prof. J. A. Douglas. Mr. W. B. Fish also gave a demonstration of a Dudell-type machine. May 12. Attendance 14.

University of Arizona

Business Meeting. April 17. Attendance 11.

The Orthophonic Reproduction of Sound, by Dr. Earl Warner. Motion pictures, entitled "Electric Transmission of Speech," and "The Single Ridge Method," were shown. April 24. Attendance 24.

Rectification of Alternating Current, by R. O. Wright;

Textile Engineering, by W. R. Brownlee, and

Commercial Phases of the Telephone, by W. T. Voss. May 1. Attendance 12.

Business Meeting. May 8. Attendance 12.

Super-Power Systems, by Geo. Diamos. May 15. Attendance 20.

A motion picture, entitled "The Audion," was shown. The following officers were elected: President, J. W. Cruse; Vice-President, T. E. Davis. May 22. Attendance 20.

University of Arkansas

Illinois Central Switching Yard, by F. H. Smith, and

Frog-Leg Windings, by Fred Ross. June 1. Attendance 9.

Brooklyn Polytechnic Institute

Vacuum-Tube Crest Voltmeters, by Paul Heise, student;

Induction Motors, by Wallace Griesman, student. Mr. Fred Siemers gave a demonstration with a Tesla coil giving a 30-inch spark. The following officers were elected: President, Ferdinand Wankel; Vice-President, William Dalton; Treasurer, Fred Wahlers; Secretary, Joseph Heller. May 21. Attendance 38.

Bucknell University

Business Meeting. The following officers were elected: President, A. Fogelsanger; Vice-President, G. Timm; Secretary-Treasurer, J. D. Johnson. May 17. Attendance 38.

California Institute of Technology

Motion pictures, entitled "King of the Rails" and "The Potter's Wheel," were shown. May 17. Attendance 46.

The Operation of a Large Power Company, by H. A. Barre, Southern California Edison Co. The following officers were elected: Chairman, Thomas Gottier; Vice-Chairman, Don Hinkston; Secretary, Alan Capon; Treasurer, Carter Blankenberg. May 28. Attendance 24.

Carnegie Institute of Technology

The Uses of Aluminum in the Electrical Industry, by Theodore Varney, Aluminum Company of America. April 28. Attendance 35.

Banquet. The following officers were elected: Chairman, J. R. Power; Vice-Chairman, W. F. Simpson; Secretary, R. O. Perrine, Treasurer, J. T. Chidester. May 18. Attendance 55.

University of Colorado

A motion picture, entitled "The Single Ridge," was shown. May 12. Attendance 25.

Business Meeting. The following officers were elected: President, A. D. Thomas; Vice-President, W. G. Edwards, Jr.; Secretary, J. A. Setter; Treasurer, R. W. Gutshall. June 2. Attendance 22.

University of Denver

Business Meeting. The following officers were elected: Chairman, Harold Henson; Vice-Chairman, Carlyle Connor; Secretary-Treasurer, Allea Ohlson. May 13. Attendance 18.

Drexel Institute

Electrical Show. May 7 and 8. Attendance over 2000.

Business Meeting. The following officers were elected: Chairman, H. D. Baker; Vice-Chairman, G. V. Craddock; Secretary, J. E. Eininger; Treasurer, T. J. Ballantyne. May 19. Attendance 23.

University of Idaho

Business Meeting. The following officers were elected: President, J. W. Gartin; Vice-President, Cecil Balkow; Secretary-Treasurer, S. Blore. May 25. Attendance 32.

State University of Iowa

Evacuating Electric Lamps, by Nathan Whiting, and

The American Institute of Electrical Engineers and Its Purposes, by Prof. A. H. Ford. May 12. Attendance 37.

Automatic Train-Control Devices, by LeRoy Wyant, Rock Island Railroad, Mr. Lyon, Ragan Automatic Train Control Device Co., and E. Wanamaker, Rock Island Railroad. May 21. Attendance 37.

Business Meeting. May 26. Attendance 33.

Kansas State College

Electrical Power Applications in the Printing Industry, by Mr. Higgenbottom. The following officers were elected: President, A. M. Young; Vice-President, K. B. Mudge; Recording Secretary, L. S. Hobson; Corresponding Secretary, John Yost; Treasurer, C. C. Tate. May 10. Attendance 66.

University of Kansas

Business Meeting. The following officers were elected: President, W. L. Immer; Vice-President, R. M. Alspaugh; Secretary, H. R. Hilkey; Treasurer, Glen Kireckhaus. May 13. Attendance 40.

Michigan State College

Business Meeting. June 3. Attendance 18.

University of Michigan

Business Meeting. The following officers were elected: Chairman, M. H. Nelson; Vice-Chairman, R. R. Swain; Secretary, H. R. Stevenson; Treasurer, W. I. Poch. May 26. Attendance 19.

Engineering School of Milwaukee

Inspection trip to the Westinghouse Lamp Works. May 21. Attendance 44.

Automobile Headlight Illumination, by E. J. Lehnen. A motion picture, entitled "Telephone Inventors of Today," was shown. June 8. Attendance 24.

University of Minnesota

The Development of the Steam Turbine, by C. C. Douglas, General Electric Co. Illustrated with slides. May 12. Attendance 70.

Montana State College

Business Meeting. The following officers were elected: Chairman, W. E. Pakala; Vice-Chairman, Wayne Kobbe. May 13. Attendance 147.

College of the City of New York

Porcelain Insulators, by Mr. Hirsch. Illustrated with slides. May 20. Attendance 14.

Production Methods in the General Electric Company, by W. W. Hambly. June 3. Attendance 26.

Business Meeting. The following officers were elected: Faculty Chairman, Professor H. Baum; Student Chairman, Harold Wolf; Vice-Chairman, Harry Hirsch; Secretary, Joseph Leipziger; Treasurer, E. F. Day. June 10. Attendance 19.

New York University

Business Meeting. The following officers were elected: Chairman, H. U. Hefty; Secretary, Henry Och. May 6. Attendance 20.

University of North Carolina

Short talks were given by the following students: Messrs. Wilson, Smith, Coe, Farmer, Ryan, Cantwell and Mason. May 6. Attendance 38.

Banquet. The following officers were elected: President, H. L. Coe; Vice-President, G. M. Wilson; Secretary, C. M. Lear; Treasurer, J. L. Cantwell. May 20. Attendance 46.

Ohio University

A New Method of Measuring Sound Intensity, by D. B. Green. Illustrated. May 13. Attendance 27.

Oklahoma Agricultural and Mechanical College

Banquet. May 20. Attendance 30.

University of Oklahoma

Business Meeting. The following officers were elected: President, G. B. Brady; Vice-President, Ralph Tyler; Secretary, J. C. Glaze. May 19. Attendance 16.

Oregon State Agricultural College

The Transmission of Pictures by Wire, by A. K. Morehouse, Pacific Telephone and Telegraph Co. Illustrated with slides. May 11. Attendance 55.

Business Meeting. May 28. Attendance 31.

Pennsylvania State College

The Transmission of Pictures by Wire, by J. W. Horton, Bell Laboratories, Inc. Illustrated with slides. May 12. Attendance 50.

Business Meeting. May 26. Attendance 20.

Banquet. June 3. Attendance 78.

University of Pennsylvania

Spring Dance. May 7. Attendance 100.

Business Meeting. The following officers were elected: Chairman, F. H. Riordan, Jr.; Vice-Chairman, W. L. Carns; Treasurer, J. T. Naughton, Jr.; Secretary, Wm. H. Hamilton. May 19.

Social Meeting. May 23. Attendance 150.

Purdue University

Public Utilities, by Stanley Green, Indiana Central Power Co. May 18. Attendance 30.

South Dakota State School of Mines

Business Meeting. The following officers were elected: Chairman, C. Allen; Secretary-Treasurer, Harold Eade. May 24. Attendance 10.

University of South Dakota

Developments of Electrical Machinery in 1925, by Louis Stverak, and

A Modern 220-Kv. Power Transmission Line, by Richard Brackett. January 5. Attendance 9.

Latest Developments in Electrical Instruments, by Will Doohen. Illustrated with slides. The following motion pictures were shown: "The Glow of the Lamp," and "White Coal." February 13. Attendance 72.

Transmission Lines in South Dakota, Mr. G. W. Day. March 9. Attendance 7.

Rearranging the Dynamo Room, by Will Doohen and Louis Stverak. April 12. Attendance 8.

A Piezo-Electric Oscillator Working at 3000 kc. and 4000 kc. per Second, by Richard Brackett. May 11. Attendance 14.

Stanford University

Business Meeting. May 26. Attendance 15.

Business Meeting. June 2. Attendance 12.

Business Meeting. The following officers were elected: Chairman, A. V. Pering; Vice-Chairman, R. H. Brandt; Secretary, J. G. Sharp. June 8. Attendance 17.

Syracuse University

A motion picture, entitled "Temperature and Motor Endurance," was shown. May 3. Attendance 18.

Water Power in New York State, by V. R. Kimball. May 24. Attendance 18.

University of Tennessee

Illustrated lecture by Mr. Nelson, General Electric Co. April 15. Attendance 35.

Business Meeting. The following officers were elected: President, F. N. Green; Vice-President, J. R. McConkey; Secretary-Treasurer, B. M. Gallaher. May 6. Attendance 20.

University of Texas

Business Meeting. The following officers were elected: President, F. W. Langner; Vice-President, R. F. Calhoun; Secretary-Treasurer, F. B. Menger; Corresponding Secretary, H. W. Zuch. May 13. Attendance 10.

Virginia Military Institute

Business Meeting. The following officers were elected: Chairman, R. P. Williamson; Secretary, M. L. Waring. May 25. Attendance 28.

University of Virginia

Hydro-Electric Possibilities Along the St. Lawrence River, by T. M. Linville;

Recent Developments of Moore Gaseous-Conductor Lamps, by H. M. Dixon, Jr., and

Recent Developments in the Reproduction of Music, by J. S. Miller. Motion pictures, entitled "The Telephone, A Modern Marvel," "The Land of the White Cedar," and "Story of a Telephone Conversation," were shown. May 19. Attendance 52.

Business Meeting. The following officers were elected: Chairman, R. C. Small; Secretary, G. L. Lefevre; Treasurer, J. Bronaugh. May 28. Attendance 10.

State College of Washington

Business Meeting. The following officers were elected: President, S. H. White; Vice-President, S. A. Bobe; Secretary, H. R. Meahl; Treasurer, Walter Beattie. June 1. Attendance 20.

Washington University

Business Meeting. The following officers were elected: President, E. B. Kempster, Jr.; Vice-President, Y. O. Waller; Secretary-Treasurer, George Simpson. May 21. Attendance 22.

University of Washington

The Superpower System, by Mr. Hutton, Pacific Coast Engineering Co. Annual Dinner. The following officers were elected: President, C. M. Murray, Jr.; Secretary-Treasurer, R. H. Crosby. June 2. Attendance 29.

West Virginia University

Inspection Trips at Carnegie Tech., by R. W. Beardslee; *Inspection Trips under Auspices of Westinghouse Elec. & Mfg. Co.*, by J. U. Neill; *The Springdale Power Plant*, by M. W. Naylor; *The Colfax Power Plant*, by E. A. Berry; *The Manufacture of Steel Shapes*, by D. S. Roush; *Interesting Things Seen at the Westinghouse Works*, by R. L. Cole; *Machine-Switching Telephone Exchange*, by R. A. Osborne; and *Submarine Indicators*, by I. L. Smith. May 21. Attendance 28.

University of Wisconsin

Hydro-Electric Construction, by Professor Meade. Banquet. May 26. Attendance 60.

Worcester Polytechnic Institute

Business Meeting. The following officers were elected: Chairman, D. A. Calder; Vice-Chairman, R. A. Beth; Treasurer, A. M. Tarbox; Secretary, C. H. Kauke. May 6. Attendance 16.

University of Wyoming

Business Meeting. The following officers were elected: President, John Hicks; Vice-President, William Buchholz; Secretary-Treasurer, James O. Yates. May 19. Attendance 10.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.

53 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.

57 Post St., San Francisco, Calif., N. D. Cook, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to ***EMPLOYMENT SERVICE, 33 West 39th Street, New York City,*** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

PUBLIC UTILITY EXECUTIVE, thoroughly seasoned for general management. X-73.

EXPERIENCED TRANSFORMER ENGINEER, familiar with design and practise relating to high-tension potential transformers and high-tension small distribution and special purpose transformers. Must be capable of original work, both theory and practise. Positions with a new division of an old line manufacturing company, not previously engaged in the manufacture of high-tension electrical apparatus. Location, Connecticut. R-9452.

DISTRICT SUPERINTENDENT, to take charge of the distribution and commercial work in a fast growing and progressive town of eighty thousand. Should be technically trained, experienced with overhead city distribution problems, customers' relations, rate interpretation, motor applications and illumination. Good working knowledge of Spanish essential. Climate healthful. Apply by letter with full particulars regarding past experience, salary, when available, references and enclose recent photograph. Location, Porto Rico. R-9898-C.

MANUFACTURING ELECTRICAL ENGINEER, who can design and plan the production of a complete line of electric stoves. Only engineer who has had practical experience producing electrical stoves will be considered. Apply by letter. Location, West. R-9839-C-R-226-S.

STEAM PLANT BETTERMENT AND SERVICE ENGINEER, with five-ten years' public utility operating experience, principally in steam electric generation. Work is in connection with plant betterment and service division of large public utility management organization. Essential that applicant be fully informed as to operation, maintenance and design of up-to-date

high-pressure steam electric stations and capable of analyzing operating results and costs, as well as rendering all kinds of service in connection with the operation of the steam and utility plants. Some traveling. Apply by letter stating salary expected, when available, and full statement of education, age, and past experience. Headquarters, New York. X-49.

STEAM PLANT BETTERMENT ENGINEER, for steam plant betterment division of large utility management company. Must have at least five years' operating experience in public utility plants. Knowledge of Spanish desirable, not essential. Underfeed stoker experience required. Apply by letter stating age, salary expected, education, when available, and full description of past experience. Headquarters, New York; location, foreign. X-50.

MEN AVAILABLE

EXECUTIVE, graduate electrical engineer, age 32, married, desires permanent position with manufacturing organization where actual selling, purchasing and manufacturing control experience can be used to advantage. Experienced in shop practise and management with knowledge of factory cost and accounting systems. Skilled in production methods, waste elimination, bonus systems and rate setting. A-4070.

GRADUATE ELECTRICAL ENGINEER, 30, married, several years practical and business, some educational experience, desires teaching position offering opportunity for research and advanced study. Excellent scholastic record, naturally adapted to educational work. Can handle electrical or power plant engineering or mathematical subjects. Westinghouse shop course and sales experience. Excellent references. C-1071.

ELECTRICAL ENGINEER, 28, B. S. in E. E., desires teaching position in electrical engineering department of university or college of standing. Desires position with prospects of advancement. Five years' experience in design, estimation and installation of electrical and mechanical equipment. Present position instructor in electrical engineering in well known Western college. Available September. B-9894.

ELECTRICAL ENGINEER, 28, single, desires position with manufacturer electrical apparatus. Five years' experience with large manufacturer electric control apparatus. Some sales experience. B-6274.

ELECTRICAL ENGINEER, graduate Lond., Eng., two years' Canadian hydro experience, five years plant maintenance. At present located Quebec, desires to improve position in Canada. Thorough practical and theoretical experience. Available in one week. At present employed. C-1419.

GRADUATE OF DREXEL INSTITUTE IN ELECTRICAL ENGINEERING, 23, five years general wiring, one year power plant construction, six months underground transmission and distribution work, including test on 13200 volt Conduit Oil Switches. De ires position electrical engineering work. Loca.ion, immaterial. C-1477.

ELECTRICAL ENGINEER, 30, married, experienced in the electrical design of power plants, substations, transmission lines, special studies, investigations, reports, etc. Technical graduate, business training. Will consider a connection with a consulting organization or an operating company. C-995-507.

ELECTRICAL AND CIVIL ENGINEER, 35, with fifteen years' experience in electrical and hydro-electric developments. Theoretical training well seasoned with actual experience in all stages from preliminary reports to construction and operation. Executive accustomed to assuming responsibility and delivering results. Fluent Spanish. B-1173.

ELECTRICAL ENGINEER, 30, married, graduate E. E., M. E., seven years' varied experience on central and substation estimating, design, construction and installation, also safety and research work. Five years in responsible positions with private corporation and public utilities. Good record and references. Desires responsible position requiring ingenuity and good judgment with industrial, engineering or small power company, preferably New York or neighboring state. Available on reasonable notice. B-5505.

RECENT COLLEGE GRADUATE, E. E., desires position as instructor in electrical engineering, preferably in New York City. C-1514.

ELECTRICAL SALES ENGINEER, wishes to represent manufacturers of electrical power and control equipment, also special illuminating equipment for industrial use. Location, St. Louis. C-1479.

ASSISTANT ENGINEER, 25, single, B. S. in E. E., two years on Westinghouse test. Desires work with public utility. Location, East, Virginia or North Carolina. C-1314.

ELECTRICAL ENGINEER, college and technical graduate, twenty-five years' broad experience in power plant and substation design, H. T. bus construction, power and light distribution, underground and line transmission, quantity surveys, specification writing, executive correspondence, and office charge, desires position with reliable utility company. Atlantic Coast preferred. B-3231.

ELECTRICAL ENGINEER, 35, married, M. I. T. education, fourteen years' experience, office and field, electrical design of power stations, substations, industrial buildings, desires position with a substantial organization where the experience stated herein can be used to the advantage of employer and employee. Familiar with appraisal work. Holds New York State Professional Engineer's license. Salary $4200. Location, New York City. B-5393.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER, desires permanent position engineering work Pacific Coast. Two years drafting, designing with electrical manufacturing company, two years substation design, rate engineering large public utility. Good character, pleasing personality, efficient worker. Several languages. European university graduate, 27, married. Minimum salary $175 a month. Present employed. Available month's notice. C-1109.

DISTRIBUTION ENGINEER, technical graduate, married, 33, five years' experience substations, steam and electric power stations, five years' experience in electrical distribution with large public utility in East. Desires location in East. Available one month. B-1410.

POWER SALES ENGINEER. Young man with ability, 34, married, desires connection with public utility who needs a real salesman for new business or contract department. Has had ten years' engineering and selling experience. Technically educated. Salary and expenses. Available August 1st. A-1330.

SUPERINTENDENT ELECTRICAL AND MECHANICAL CONSTRUCTION AND OPERATION-EXECUTIVE, 48, married, technical education, wide experience, five years in Orient, design, construction, installation and operation, power, light and industrial plants, steam, hydro-electric. Special experience all kinds electrical apparatus and equipment, turbines, boilers, auxiliaries, high tension transmission, substations, distribution systems, building construction, mill machinery in public utility and industrial plants. Available short notice. Location immaterial. C-408-127.

GRADUATE ELECTRICAL ENGINEER AND MECHANICAL ENGINEER, 27, married, one year G. E. test, one year of substation design with large public utility. Work consisted mostly of switchboards, control and protection schemes, and checking drawings. Available on reasonable notice. Location, Middlewest or East. C-1068.

MECHANICAL ELECTRICAL ENGINEER, married, eighteen years' experience covering General Electric test, substation and power station design and operation for steel and wire mills, electrical cable manufacturing and sales. Executive and industrial development ability. A-4652.

SALES ENGINEER, 34, well acquainted with Eastern public utilities, and large electrical jobbers; twelve years' experience. At present connected with large manufacturer of line material and substation equipment. Salary and expenses. Available June 30th. C-1551.

EDITOR-ENGINEER, will edit house organ for transportation company, public utility company, manufacturing company, or get up catalogue, advertisements or historical booklet or descriptive matter. Three and one-half years' experience as department editor of magazine, and electrical engineer of a number of years' standing. C-1490.

GRADUATE ELECTRICAL ENGINEER, Canadian, 27, married, finished Alexander Hamilton Institute Modern Business Course. Three years naval wireless work. Canadian General Electric Students' Test Course, nine months operating department, two years electrical design on hydraulic generating stations. Wishes position as engineer or executive with small growing manufacturing company or public utility. Location, Eastern States. Available fifteen days' notice. C-1524.

ELECTRICAL ENGINEER OR EXECUTIVE, twenty years' experience in electrical design and construction of generating and substations, also transmission and distribution, also industrial installations. Can also sell electrical equipment and commercial power. Desires responsible executive position. Permanence more important than location. B-3711.

LICENSED ELECTRICAL CONSTRUCTION ENGINEER, at present employed electrical field superintendent of large firm doing heating, plumbing, electrical contracting business. Four years' experience with above firm estimating, sales, purchasing, seven years with large public utility electrical engineering and new business departments. Minimum salary $5000. Location, New York or vicinity. Available reasonable notice. C-1548.

RADIO COMPASS ENGINEER, technical graduate, desires position with reliable concern in this capacity. Present employed by U. S. Navy Department on position and direction finding radio. C-723.

ASSISTANT EXECUTIVE, B. S. and E. E. degrees, five years' well balanced experience in all phases of distribution and power substations and their commercial aspects, and one year's experience in administrative office of manufacturing company, three years in supervisory capacity. Desires position with electrical company requiring technical, commercial, and executive ability. Minimum salary $3600. Location preferred, lower Great Lakes States. B-7315.

ELECTRICAL ENGINEERING GRADUATE, (B. S. in E. E.) 30, single, ten years' electrical construction and maintenance of industrial plants, substations, etc., one year electrical design. Desires position in electrical construction with public utility or contracting company. Field work preferred. Minimum salary $2600. Eastern location. C-1525.

POWER ENGINEER, 38, married, electrical graduate, also special study M. I. T., Allis-Chalmers test, 13 years' experience installation power plant machinery, maintenance, general construction, operation and supervision in public utility. Desires position distribution engineer with a public utility or similar work with opportunity for advancement. Location, United States. Available at once. A-4018.
